Hand ladles are used to remove the molten metal and a fairly clean separation can be made between the metal and the fused chloride metal. Under normal operating conditions and with reasonably trained operators this should be more than 98 per cent pure.

This metal then passes to a refinery where it is either refined for sale as pure metal 99.7 per cent or better or alloyed for sale as one of the constructional alloys.

In the refinery the metal is first melted in large cast steel crucibles of 2-ton capacity; during this process Basic Melting flux is used to minimize local oxidation. When the charge is molten, the alloying additions are made—aluminum and zinc directly; the manganese being added in the form of manganous chloride. The charge is then refined with a refining flux, Basic E, which is stirred into the melt to carry down the suspended particles of chloride from the electrolysis metal and to remove the remains of the melting flux. The refined metal is then poured into a clean crucible and superheated under cover of refining flux at a temperature above 1472 deg. F. for over 15 min. The charge is then cooled rapidly to 1328 to 1382 deg. F. and poured either onto a continuous ingoting machine or into 300 lb. crucibles which are then poured off into extrusion billets or rolling slabs.

Fluxes in Magnesium Refining

INASMUCH as all melting and refining processes for magnesium and its alloys require the use of fluxes, C. E. Nelson of the Dow Chemical Co.'s metallurgical department emphasized their unique characteristics and proper use in his paper on "Melting and Refining of Magnesium."

Four main types of melting were discussed: Open-pot; crucible; reverberatory, and die-casting. The open-pot method makes use of a flux having the composition 55 KCl, 34 $MgCl_2$, 9 $BaCl_2$ and 2 CaF_2. The flux provides protection during melting. It is stirred through the molten metal bath and agglomerates oxide or similar foreign bodies; then on quiet standing separates away, leaving the refined metal ball floating in an encircling layer of molten flux. It forms only a thin fluid film over the surface of the molten metal, which may be parted for hand ladling processes and tends to cover the metal again after the ladle is removed.

The open pot method is used generally in the following process: 1. Alloying and secondary smelting in the production of magnesium ingots; 2. in sand foundries for premelting and to a lesser extent for the production of small castings requiring hand ladling; 3. in permanent mold foundries for premelting and also direct ladling to castings; 4. for continuous methods of preparing metal in the production of billets or ingots from which wrought products are fabricated, and 5. in general scrap recovery.

For the crucible process of melting and refining magnesium, a flux is used that is thinly fluid at the start and then dries out or thickens to leave a protecting crust on the pot surface until the time of casting. Such a flux contains 20 KCl, 50 $MgCl_2$, 15 CaF_2 and 15 MgO. When pouring, the crust can be readily skimmed off or held back, so that the molten metal is not contaminated with the flux.

Crucible melting is used principally in sand and permanent mold casting as a single step melting, refining and pouring operation, or more commonly as a second step following the transfer to a casting crucible of molten metal from premelting units like large open pots or tilting crucibles. It is also used in the batch method of melting, alloying and pouring billets or ingots from which wrought products are fabricated and in the refining of die-casting scrap.

Successful experiments in melting magnesium in the resistor-heated type of Detroit electric rocking furnace led to further experiments with a reverberatory hearth furnace having a capacity of 1500 lb. of magnesium and using oil and gas as fuels. Based on these preliminary experiments, a furnace with a capacity of approximately 12,000 to 20,000 lb. of magnesium was put into use. This furnace has operated for about two years and during that time six more similar furnaces have been placed in service.

Below the metal line these furnaces are lined with a refractory that is relatively non-reactive with the fluxes and the magnesium. Linings with the longest service record are of Tercod, a carbon-bonded silicon carbide refractory having a carbon facing next to the metal bath. The walls and roof are of high-grade firebrick.

In operation the solid charge is fed mechanically into one end of the furnace onto a preheating shelf, from which it is pushed into the bath by the introduction of the next charge. Metal is dipped or pumped out of a well at the opposite end of the furnace.

Consumption of flux for melting magnesium in these units has been the same as previously was required for standard open-pot operation. Similarly the melting loss closely parallels that obtained in the more conventional methods of melting. Fuel efficiency is much better and would amount to about two-thirds of that used in open-pot melting. The outstanding feature of the open hearth operation, Mr. Nelson pointed out, is the very high melting capacity. The units in operation are capable of melting continuously at the rate of 4000 lb. of metal an hour.

Safety of operation is another notable feature, since the charging and preheating is all automatic and spatterings cannot reach the operator. Further, the likelihood of a runout is remote because the refractory construction is cold on the outside.

The field of use of the reverberatory, he continued, is in large-scale continuous melting of magnesium or alloy ingot or heavy scrap. In such a process it operates as a premelter for alloying or foundry operations. It is not considered suitable for the melting of fine magnesium or light scrap because of the difficulty of applying adequate mechanical puddling and the development of the large amounts of sludge or dross that accompanies the processing of these materials.

Protection during melting and holding is provided by the open-pot type flux. Ultimate refining of the metal is accomplished in open-pot or crucible process that follows.

The die-casting process makes use of a flux, 57 KCl, 28 $CaCl_2$, 12.5 $BaCl_2$ and 2.5 CaF_2, that gives no surface protection but is used only for refining the metal. Surface protection in this method comes from the use of a sulphur dioxide atmosphere, which is maintained in a closed dome over the pot. Only a very little flux is used as protection during melting down and this is stirred through the metal for refining. After a few moments of quiet standing, this flux together with agglomerated oxides and dross, sinks to the bottom of the pot and is removed with the sludge.

The melting and refining of die-casting scrap presents a special problem since a certain proportion of

carbonaceous materials, lubricants and other impurities are present on the scrap. Using the flux described for the die-casting process is not satisfactory as a reddish scum or film of the carbonaceous material seems to stay suspended throughout the metal. This behavior is eliminated through the melting of such scrap in open pots or crucibles using the crucible-type flux. This flux has the necessary characteristics to agglomerate the carbonaceous film and refine this material.

The melting and refining of crystalline magnesium, the product of the ferrosilicon-dolomite reaction, is somewhat difficult, Mr. Nelson said. It is finely divided and hence oxidizes readily. Furthermore, a variable and sometimes appreciable amount of oxide, nitrides and other impurities are occluded with the crystals. Because of these more care must be exercised during the melting of the crystals to use a fluxing technique that will not permit oxidation. Normally this is done by charging the crystals into a "heel" of molten metal purposely left over from a previous batch, or into a bath of melted flux in the bottom of the pot. Liberal quantities of the same flux are dusted over the solid charge and as often as required to prevent the start of oxidation. The crystals are puddled into the metal or flux bath as rapidly as possible. After the charge has all melted down, more flux is added and stirred thoroughly through the bath, in order to separate the oxide and dross inclusions.

If the crystals are particularly clean and free from oxide and other undesirable materials, it may be sufficient to proceed with the normal alloying processes, followed by stirring of the fluxes through the bath and finally settling out of the dross and sludge and pouring of the refined alloy into ingots or castings.

If the crystals contain a large amount of oxide, or appreciable oxidation takes place during the melting, it is desirable to allow a few minutes of quiet settling and then dip from the bottom of the pot as much of the dross and oxide as possible before proceeding to the alloying and refining steps.

The magnesium crystals usually are relatively low in iron content but may contain sodium, potassium, calcium and sometimes silicon as impurities. For all practical purposes, all except the silicon are removed by reaction with the flux in the melting and refining process. The iron content, however, will tend to increase up to the saturation value if melted in steel pots. The iron may be precipitated after the principal alloying materials have been added, usually by the addition of manganese to a saturation value for a temperature above that at which the metal is to be poured. When manganese is present up to its solubility value, particularly in the presence of aluminum, iron is greatly reduced in solubility or tendency to stay in suspension, and is rapidly precipitated to the bottom of the pot.

Manganese is introduced as manganese chloride or either Dow's No. 250 or 320 manganese flux, the former if the process is carried out in an open-pot and the latter if in a crucible.

The grain structure of magnesium and its alloys can be markedly refined by a superheating treatment of 200 deg. to 400 deg. F. above the melting point. In this behavior, it is considered to be much like cast iron, and the theories and hypotheses used for the explanation of the behavior of cast iron may be applied to magnesium with the substitution only of the alloy and the type of impurities.

Superheating effects may be obtained as low as 1500 deg. F. but the time required at this temperature is rather long, being several hours. As the temperature of superheating is raised to about 1700 deg. to 1750 deg. F., the time required to get the effect gradually drops off to approach zero.

o o o

Bureau of Mines "Baby"—Electrolytic Mn

ELECTROLYTIC manganese production capacity in this country is approximately 5 tons a day, R. S. Dean, assistant director of the Bureau of Mines, reported in "The Present Status of Electrolytic Manganese and Its Alloys." It has been used in magnesium alloy bomb casings, stainless steel tests, by the Mint for new nickels and has been sent to England under lend-lease principally for addition to aluminum alloys.

Present practice, as carried out at the Boulder City project, starts with a manganese dioxide ore containing about 20 per cent manganese which is reduced to MnO. The MnO is dissolved from the ore in spent electrolyte which contains about 38 to 47 grams per liter of free sulphuric acid, 135 grams per liter of ammonium sulphate and 10 to 12 grams per liter of Mn as sulphate. In the leaching step the manganese is built back up to 32 to 36 grams per liter of Mn as sulphate; the pH is adjusted to neutral by gaseous ammonia and passed through thickeners. The electrolyte is purified by adding H_2S which precipitates the heavy metals. After filtering, ferrous sulphate is added to the solution and oxidized with air and the solution is filtered and clarified on a pre-coat filter.

The purified catholyte is electrolyzed in a diaphragm cell using stainless steel cathodes and lead-silver anodes. Current density is about 45 amp. per sq. ft. Current efficiencies of 60 to 65 per cent are regularly obtained. The brittle manganese is stripped from the cathode by bending. The stripping efficiency, in good weeks, has reached 94 or 95 per cent. The average for a year has been 82.5 per cent. The reduction step has been carried on satisfactorily in either a Skinner muffled-hearth furnace or a Taylor multitube furnace. With either, direct addition of oil is a satisfactory reducing agent.

The managanese is substantially pure, except for 0.03 to 0.07 per cent sulphur.

An interesting use of electrolytic manganese is in an age-hardening alloy of approximately 60 per cent copper, 20 per cent manganese and 20 per cent nickel. This alloy is being rapidly commercialized. Its hardening range (from 80,000 soft to 180,000 hard) and fatigue strength (60,000 lb. per sq. in. for 108 cycles) are substantially greater than that of beryllium copper.

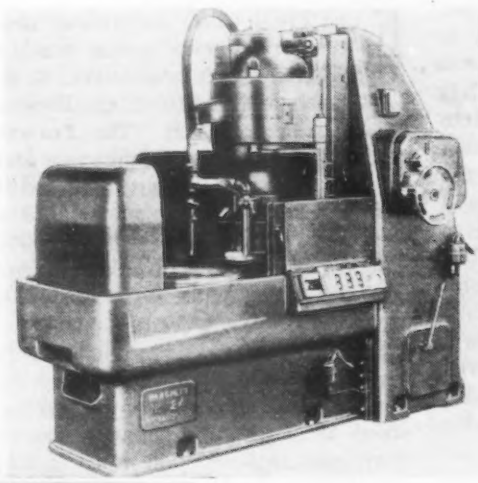
The price of electrolytic manganese has held back the demonstration and utilization on a substantial scale of its possible advantage in ferrous alloys. Experiments undertaken by the Bureau of Mines indicated a recovery of manganese in furnace additions to stainless steel of 87.8 per cent compared with 84 per cent for low carbon ferromanganese and for ladle additions 89.9 per cent, compared with 72.7 per cent for low carbon ferro. There was no measurable increase in the carbon or phosphorus content of the heat. Recovery of manganese was more consistent from heat to heat than when using ferromanganese and because of the convenience of handling, weighing and shoveling, electrolytic manganese and the smaller bulk and weight of the addition, the time required to prepare a heat for tapping is shortened.

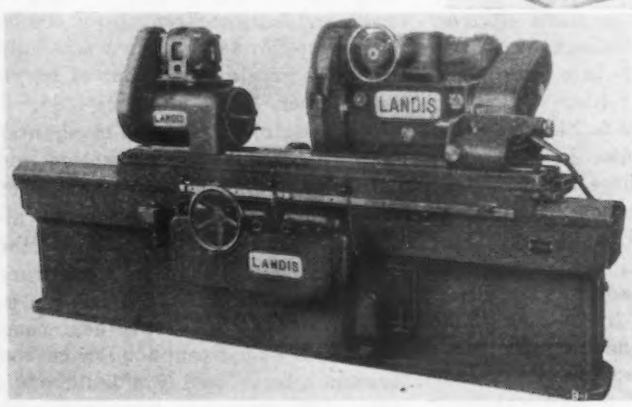
New Equipment . . .

Machine Tools

. . . Recent developments in production and tool grinders, boring mills, Swiss type automatics, gear shavers and other units are described and illustrated in the following pages. Other machine tool developments will be described next week.

THE wheel feed mechanism on the 10 and 14 in. Type CH plain hydraulic grinders put on the market by *Landis Tool Co.*, Waynesboro, Pa., has been redesigned. Accurate setting for the hand feed is provided by a large micrometer ring at the rear of the feed-up handwheel. Graduations on the ring are normally read in thousandths in terms of work diameter reduction, but a simple adjustment permits graduations to be read in "tenths." The wheel feed is automatically reset at the end of each grinding cycle without changing the position of the wheel feed handwheel. Hydraulic straight infeed, supplied only on order, retains the automatic wheel feed feature. Stroke of the infeed is adjustable from 1 to 3½ in. and slow feed from 0 to 0.120 in. on the work diameter. An automatic compensating device prevents changes in oil viscosity from influencing accuracy of feed. A hinged hood at the front of the wheel guard is adjusted inward as the wheel wears down. Smooth headstock face plate rotation is assured through anti-friction bearings and an all multiple V-belt drive. A wheel truing bar with micrometer adjustment is built into the footstock base.



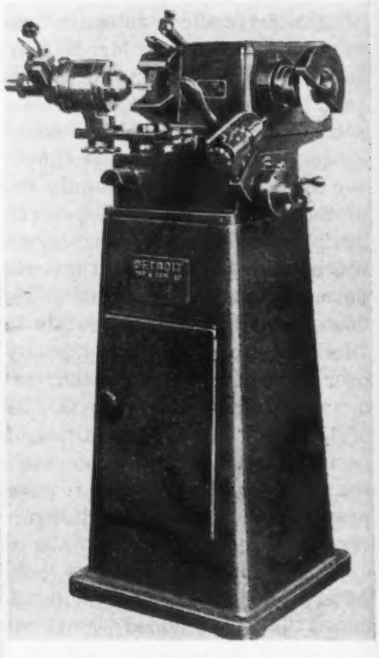


Surface Grinders

THE No. 24 vertical spindle rotary surface grinder has been brought out by *Hanchett Mfg. Co.*, Big Rapids, Mich. The structural proportions are said to be considerably heavier and stronger than conventional type machines of equal capacity. The 30-in. rotary magnetic chuck is equipped with a Neu-T-Rol demagnetizing switch and is traversed into grinding position by push-button control. The grinding wheel head has hand, power or automatic traverse with power being furnished by a 2-hp. 900 r.p.m. motor, while the coolant pump is driven by a ½-hp. motor. The grinder is equipped with an ammeter for determining the cutting action of the grinding wheel.

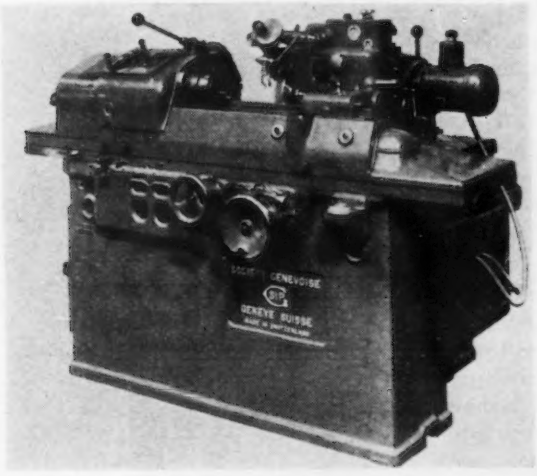
Tap Reconditioner

A NEW spindle head that accommodates interchangeably a wide range of motor types for various service voltages, phases and frequencies has been added to the tap reconditioner marketed by the *Detroit Tap & Tool Co.*, 8432 Butler, Detroit 11. Standard motors are 220 to 440 volt, 3 phase and 110 volt, single phase for either 25 or 60 cycle service. The spindle assembly is mounted on large dovetail ways in the pedestal base. The tap chamfering unit is of the precision collet type and will accommodate collets from the smallest machine screw size up to the 1¼ in. standard tap shank size, including long shank taper taps.



Precision Thread Grinder

THE RU-2 high precision thread grinder manufactured by *Societe Genevoise*, Geneva, Switzerland, grinds internal and external threads and is equipped with a micrometer stop which permits setting to 0.00005 in. Both wheel and work profiles may be inspected as to angle and radius by means of a microscope, which may be tilted out of the way. The wheel truing device is manually operated and has a dial gage reading to 0.0001 in. A temperature compensator permits variation of the pitch of the threads ground, to allow for the cooling effect of the coolant supply. The compensator works in conjunction with a device which automatically corrects for error in pitch of the lead screw. The external grinding wheel is 10 in.



in diameter, while internal grinding wheels are available from 1⅛ to 3½ in. in diameter. The grinder is being distributed by the *Cosa Corp.*, Chrysler Building, New York.

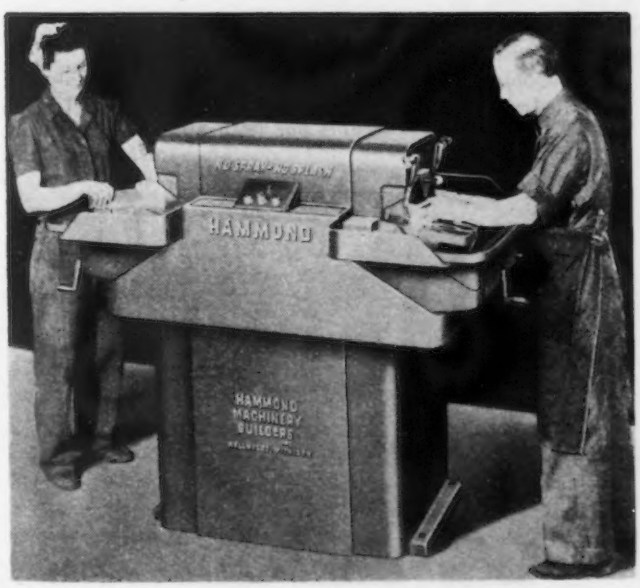
Carbide Tool Grinders

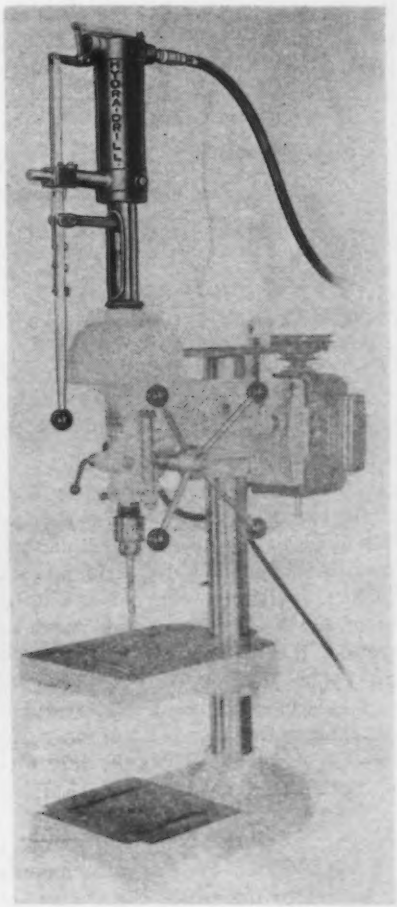
A NEW coolant control feature enhances the facilities for properly flooding the tool while wet grinding on the 10 and 14 in. carbide tool grinders built by *Hammond Machinery Builders, Inc.*, 1612 Douglas Avenue, Kalamazoo 54, Mich. Large splash pans around the table provide adequate protection to the operator and prevent coolant splashing onto the floor. A safety cup disk prevents the possibility of tools dropping into the well of the cup wheel. It moves in with the hood and table as the machine wears. A concealed, swivel no-splash guard on the wheel closes one side of the cup wheel while the other side is in use.

The company has also equipped its Series RW floor stand grinders for magnesium grinding with a multi-V-belt driven spindle, explosion proof electrical equipment, hinged wheel guards of plate steel with exhaust connections and spark deflectors, adjustable work rests, tool tray and removable water pot.

Vertical Turret Mills

A SPECIAL coolant system is available from the *Rogers Machine Works, Inc.*, 125 Arthur Street, Buffalo 7, for use on both the standard and high speed models of its 36 in. vertical turret mills. Two streams of coolant are delivered to the tool and the work through flexible tubing. The self-priming pump, driven by a direct connected fractional horsepower motor, is mounted on the base. The coolant is cleaned before being recirculated.





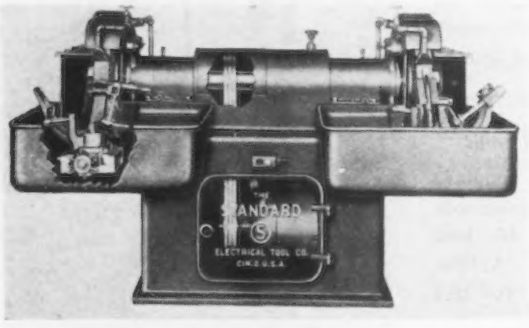
Drill Press Power Feed

A CONTROLLED automatic fully adjustable power feed for most makes and models of drill presses is being distributed by the *General Pacific Corp.*, 1800 South Hooper Avenue, Los Angeles 21. Powered by air, the Hydra-Drill is designed to automatically operate a drill press so that the customary hand feed is unnecessary for fast production work. Adjustable stops permit accurate adjustment for drilling, counterboring, spot facing, blind-drilling, reaming and other operations. The range of feed is infinite. Finger-tip control permits immediate release of the automatic feed. The rate of feed of the spindle can be adjusted so that the pressure of the drill on the work is right for any particular drilling operation regardless of the size of the drill used and the rate of speed at which the drill is operated.

Chisel Grinder

FOR grinding chisels uniformly, the *Standard Electrical Tool Co.*, 2490 River Road, Cincinnati 4, has introduced a heavy duty double end self-contained belted motor driven grinder. Twenty-inch diameter resinoid bonded wheels are mounted on a spindle operating at 1700 r.p.m. The wheels are

2½ in. face. The hoods or guards permit quick renewal of the grinding wheels. A tank fitted with motor driven pump with a capacity of 10 gal. per min. is mounted on the back of the machine. The chisel is secured in a quick acting holder which permits unskilled operators to accomplish a uniform finish on the chisel blanks. After the heel of the chisel has been ground, the attachment is swung 90 deg. to a position were the desired uniform cutting edge is acquired. The attachment is intended not only for grinding new chisel blanks but also for re-dressing used chisels.



Swiss Type Automatic

A NEW set of five attachments which increases the range of work that can be handled on the Wickman No. 2 Swiss type automatic is announced by the *Wickman Corp.*, 15533 Woodrow Wilson Avenue, Detroit 3. The three-spindle attachment, shown mounted on the machine, may be used for centering, drilling, reaming, threading or tapping. No. 1 spindle is non-rotating and is used for centering and drilling. No. 2 spindle may either rotate in the opposite direction from the machine spindle or be held stationary. It is used for drilling and reaming operations. No. 3 spindle over-runs the machine spindle for precision threading but it can also be held stationary and used for drilling or reaming.

The high speed drilling attachment, center, consists of a sliding head rotating in the opposite direction from the machine spindle. The threading attachment, at the left of the picture, employs a self-opening die head and consists of a hollow spindle with a sliding head that over-runs the machine spindle. The slotting attachment, to the right in the picture, is used to slot or mill the end of any part produced on the machine. An attachment is also provided for the making of long, accurate tapers by means of an accurately ground form bar.

Tapping Machine

A SERIES of light duty lead screw tapping machines has been announced by *Detroit Tap & Tool Co.*, 8432 Butler Avenue, Detroit 11. The LTM machines have a capacity up to ⅞ in. diameter and 14 pitch in mild steel. The tapping head and motor may be raised and lowered by a rack and pinion operated through worm gearing and may also be adjusted horizontally through an arc of approximately 90 deg. Multiple tapping heads can be applied. Interchangeable pulleys with V-belt drive are provided for changing spindle speeds through 64, 160 and 400 r.p.m. A multiple disk type clutch on the drive may be set by hand control to any degree of operating pressure.

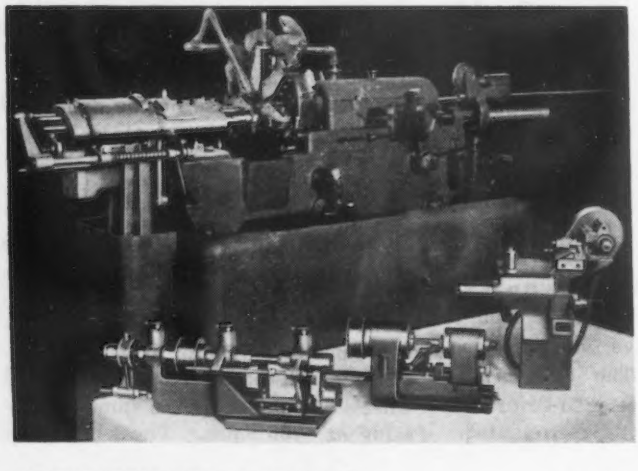
Band Filer

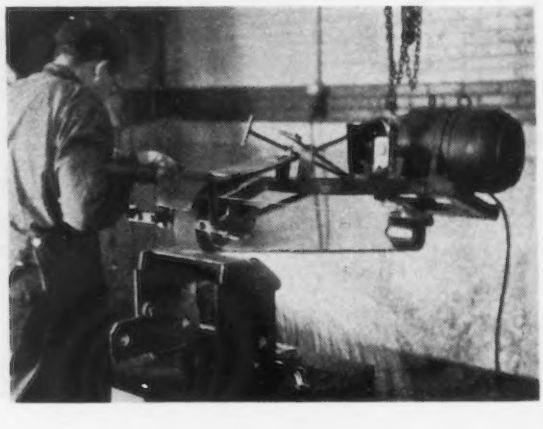
A CONTINUOUS band filing machine is offered by *Continental Machines, Inc.*, 1301 Washington Avenue, South, Minneapolis 4, for file broaching operations on metals, alloys, plastics, fibers and wood. It is claimed that smooth finishes with tolerances of 0.001 in. can be obtained by comparatively unskilled labor.

Twelve different types and sizes of file bands range from ¼ to ⅜ in. wide in ovals, half rounds or flats. Internal filing work is performed by unsnapping the file bands and threading through the work. The filer is equipped with Speedmaster infinitely variable speed pulleys to give any cutting speed from 50 to 250 ft. per min. All controls are conveniently located. A blower for removing chips is provided at the point of work.

Abrasive Belt Grinder

HEAVY duty Metalite cloth belts with smooth running Uniflow joints have been developed by the Behr-Manning Corp., Troy, N. Y., for use on swing frame grinders in place of solid wheels. It is claimed that with the abrasive belt, the grinder cuts faster and cooler, production is increased and grinding costs reduced. The belt is shown applied to the new Fox swing frame abrasive grinder. The unit has been applied to grinding welds and smoothing up armor plate.





Telechron Electric Timekeeper, Warren Telechron Co., Ashland, Mass.

The inside story of a clock

In the manufacture of this pre-war Timekeeper, many individual parts are made from brass. For example, the rotor units are produced from Free Cutting Brass Rod in an interesting high speed automatic operation which, using a five-turret lathe, counterbores, spots, drills, reams, forms and cuts off an endless stream of finished caps.

Revere Brass is used widely in the manufacture of watch and clock parts and in a wide variety of chronological and recording instruments such as fire alarm systems, telegraph mechanisms, ship chronometers, watchman call boxes, and the like.

In this particular manufacturing field, Revere offers a variety of tested materials such as Sheet, Strip and Roll Brass. Also Free Cutting Brass Rod in all standard sizes and shapes. Brass Sheet Stock is offered in various widths, gauges, lengths and tempers, in an infinite variety of combinations depending upon the alloy and characteristics required. Special finishes are available for many alloys and products.

• • •

While primarily engaged in supplying Sheet, Strip, Rod, Bar, Tube and other mill products, Revere is also prepared to furnish a considerable number of fabricated semi-finished materials and parts not only in copper and copper base alloys, but also in magnesium and aluminum. Its intricate die-pressed aluminum forgings, especially as utilized by the aviation industry, are a case in point. If you have unusual technical problems involving the use of any Revere products, we shall gladly give you the benefit of our knowledge. Address Executive Offices. No obligation, of course.

Assembly Line . . . .

STANLEY H. BRAMS

• 1944 truck program assumes final form as Army parcels out its cutbacks . . . Prices are worrisome to producers . . . Chevrolet multiplies aluminum forgings output.

DETROIT — The truck production program for 1944 appears finally arranged. But its details remain unrevealed at the time of this writing.

The Army has completed its scheduling of the cutbacks sought by WPB as the only means by which facilities could be made available for essential commercial truck production. Now that these cutbacks have been made, WPB knows how many units can be shifted to civilian channels. Assignments to individual companies will be on an historical basis, and WPB is now compiling past production statistics required to figure the 1936-through-1940 production averages which will provide the basis for forthcoming company quotas.

A few cutbacks of military truck requirements have already developed. The half-trac vehicle program undertaken by White, Autocar and Diamond T, as reported earlier in THE IRON AGE, has been all but eliminated. White announced that the cutbacks at its Cleveland plants where all the motors and many basic parts for these jobs have been produced, will reduce employment about 10 per cent.

The Dodge program is reported to have been cut sharply in recent weeks. An estimated 30,000 vehicles are said in trade circles to have been shaved from the company's 1944 schedules, representing probably a third of its projected work for this year. Company officials, however, stated that the cutbacks were considerably smaller than this. There were an indefinite number of layoffs.

Production of quarter-ton trailers for jeeps at Willys has been modestly reduced, but inasmuch as these units are built mainly of wood, the cutback will have little effect on steel ordering. Jeep output continues heavy at Willys, primary producer in this classification and, in fact, has recently been somewhat enlarged.

Now that the Army has settled fairly definitely on its 1944 program, cutbacks can be expected to arrive thick and fast during March. Thereafter schedules should be fairly firm, changing not so much as a result of policy but as a result of unforeseen turns, good or bad, in the war.

An interesting short-cutting of customary paper work is being pondered by the WPB Automotive Branch, it appears, as a means of expediting forthcoming commercial vehicle production. First step in this plan, trade circles say, may be the issuance of CMP allotments for 1945 vehicle production, covering work which actually is planned for 1944.

This plan's advantages deriving from that move are not entirely clear from the strict CMP interpretive standpoint. The aim would apparently be something radically new in the framework of the plan—the moving ahead of allotment numbers from one period to an earlier period. And after this was done, the one advantage gained would be the time cycle required for completion of the paper work.

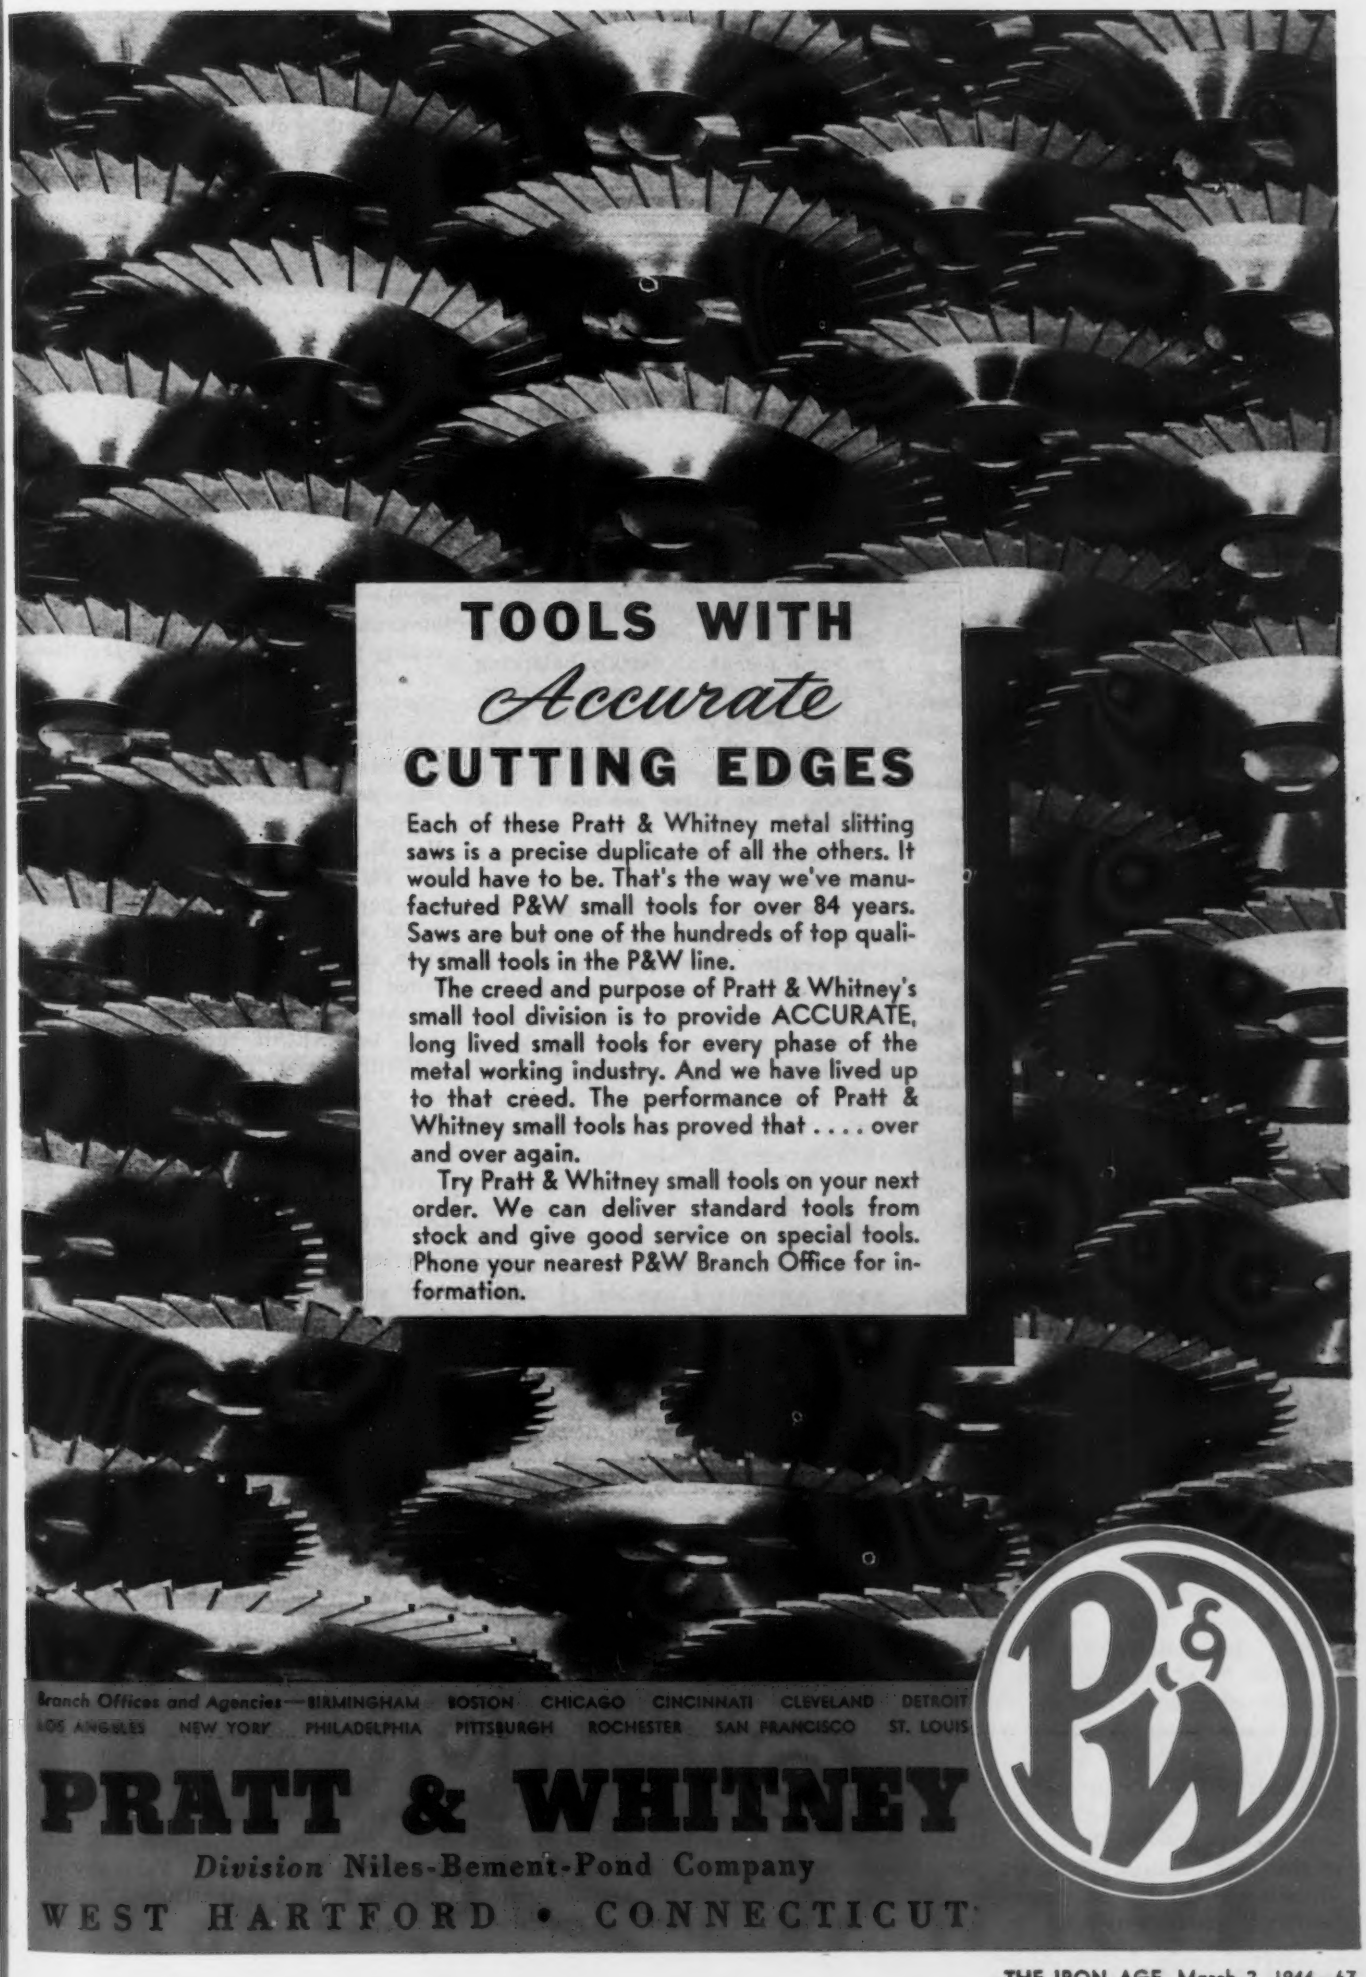
This equivalent advantage would derive even though the allotments could not be brought forward. In such an event, it would be conceivably possible for the claimant agency to duplicate, on new 1944 allotments, the information and details already developed for the 1945 allotments previously placed, reducing paper work time to a minimum.

AS room develops for commercial truck output, the attention of manufacturers is being concentrated more and more closely on the price problem. OPA has allowed Ford an increase of 11 per cent on the retail price of one truck model. Reo has been permitted price increases on five models, none of them notably different from the Ford advance.

Chevrolet has an application in for price increases straight through its line, but OPA as yet has made no decision. The rest of the industry, meanwhile, is awaiting the outcome of this application, figuring it will set a precedent for complete line price changes. Some competent sources within the truck industry believe that OPA's determination will be to permit price increases to the actual extent of labor and material cost advances—which would, of course, act to reduce the percentage of profit involved.

It appears probable that this uncertainty on prices is holding up distribution of 1944 commercial trucks to a vehicle-hungry trade. Approximately 3000 civilian models were completed during January, much more than were expected, primarily due to the cancellation of some rather minor Lend-Lease orders on jobs identical with ordinary civilian vehicles. The

PEACETIME STOVES: *In a Cleveland plant where armor plate for tanks was being turned out a year ago, gas stoves which meet pre-war laboratory requirements are now in production. They will reach the market sometime in March or early April. Grand Home Appliance Co. is making these units.*



TOOLS WITH
Accurate
CUTTING EDGES
Each of these Pratt & Whitney metal slitting saws is a precise duplicate of all the others. It would have to be. That's the way we've manufactured P&W small tools for over 84 years. Saws are but one of the hundreds of top quality small tools in the P&W line.
The creed and purpose of Pratt & Whitney's small tool division is to provide ACCURATE, long lived small tools for every phase of the metal working industry. And we have lived up to that creed. The performance of Pratt & Whitney small tools has proved that . . . . over and over again.
Try Pratt & Whitney small tools on your next order. We can deliver standard tools from stock and give good service on special tools. Phone your nearest P&W Branch Office for information.

Lend-Lease completions thereby became the largest part of the total of 3000 civilian completions. But these completions, like others, are rumored sitting idle awaiting determination of pricing policies.

Admittedly, OPA recognizes that manufacturing costs have increased notably, but the agency does not want to give ground too easily or too widely. This is proved by the size of the grants already made, all of them considerably smaller than the 25 per cent spread which manufacturers maintain really measures cost increases since 1941.

The truck companies are not so concerned over the immediate effect of prices as they are over the longer range aspects. With military truck production continuing, the producers might be able today to sell new trucks at levels very near the pre-war prices, and at the same time show a modest profit on them. But once the volume prop of war work is removed from the factories by cutbacks anticipated for later this year (not the current ones), then commercial truck manufacture could never be undertaken without substantially larger price tags. The manufacturers figure it is much easier to obtain those price concessions now, at the start of a program, rather than midway through it. The enlarged profits involved in the meantime would be quite definitely small. And the vehicle prices would mostly be right alongside prices paid in recent months for equivalent jobs built before the war began, on which $15 increments have been added for each of the 25 months since January, 1942.

PROGRESS reports tinged with significant post-war implications came out of the auto industry last week. Chevrolet Division of General Motors told that last year it turned out 76,000,000 lb. of aluminum aircraft forgings, making it the second largest producer in that field. In 1942, output was but 8,200,000 lb. Three plants put out most of this production, a fourth having gone into service only last November. Several hundred kinds of items were manufactured. In addition, Chevrolet cast 2,000,000 lb. of magnesium in its one foundry where eight different castings were made, all for Pratt & Whitney aircraft.

Amplex Division announced that its production of powdered metal products exceeds 250,000 lb. daily. Much of this manufacturing is in the form of self-lubricating, oil impregnated bearings, parts employed in more than 6000 different war applications. A small share of it is in a new product of interest—tool steel.

Where 3-lb. pieces represented a practical maximum size in pre-Pearl Harbor production, Amplex is now pressing big units weighing in excess of 100 lb. These are now handled on a Clearing hydraulic press, said to be the largest automatic briquetting machine in the world, put into service late last year.

o o o

Ore Price Increase Prior to Start of Shipping Deemed Vital

Cleveland

• • • **In order to start** promptly moving the 1944 merchant iron ore supply, which will constitute more than 25,000,000 tons of the season's projected ore quota of 93,000,000 tons, operators are pressing OPA for some means of quickly balancing rising cost factors with ceiling prices. The ore season promises to open early this year and it is held here that price relief is necessary to assist operators whose mines are now in the red.

Smarting under last season's poor financial showing, the industry has been working with OPA in an effort to present sufficient data to permit consideration of increased prices. A formal price increase proposal to OPA is imminent and promises to be on OPA's dockets between March 1 and March 10. This proposal will not only show that cumulative costs accruing since 1939 would warrant a price increase, but also that the final result of present labor wage demands may in addition require a further rise.

Cumulative costs, which have affected mine incomes in the past two seasons, include a number of intangible costs resulting from reduced efficiency, more extensive equipment repairs, higher operating supply costs, make-work policies imposed by the union, increased shipping costs, etc. Above and in addition to these costs the likely outcome of some 22 union demands, among which are increased wages and improved working conditions, promises to add as much as 50c. per ton to production costs of underground mines and probably no less than 15c. per ton to open pit mines.

Inasmuch as solution of the mine-union demands hinges on the outcome of the steel union case, it is expected that the ore industry will immediately propose a higher ceiling price under which its escalator clauses could operate. At the same time the industry will request the establishment of an adjustable pricing provision that would permit the sale of ore at an open quotation with the price to be confirmed after OPA has established a maximum ceiling price. This plan would permit retroactive billing of the differential between the new maximum ceiling price and whatever ceiling price was in effect at the time of the sale.

Best estimates of the ceiling price which the industry will request in consideration of present cost conditions vary between the formerly requested $4.75 and $5.00 per ton for Mesabi, non-Bessemer ore assaying 51.5 per cent iron, delivered at lower lake ports. While such a ceiling price would still not constitute the actual price, as ore often sells below the published price, it would provide a ceiling high enough to permit competition beneath it even with only presently known costs considered. If and when higher wages enter into costs, a further advance is indicated.

•

Lake Ore Consumption Declined During January

Cleveland

• • • **Lake Superior** iron ore consumption during January in the United States and Canada fell slightly below the total for December. In the United States, consumption was 7,291,607 gross tons in January as compared with 7,313,034 gross tons in December. Total consumption of Lake Superior ores for January was 7,481,653 as compared with 7,509,096 tons in December.

Total ore stocks on hand in the United States and Canada as of February 1 were 36,059,302 gross tons, with 30,746,228 gross tons on hand at furnaces, and 5,313,074 gross tons remaining at Lake Erie docks. Stocks a year ago were slightly better, totaling 39,742,766 gross tons.

Of blast furnaces depending principally on Lake Superior ores, 182 out of 196 were in blast as of February 1. Of these 175 are in the United States and seven in Canada.

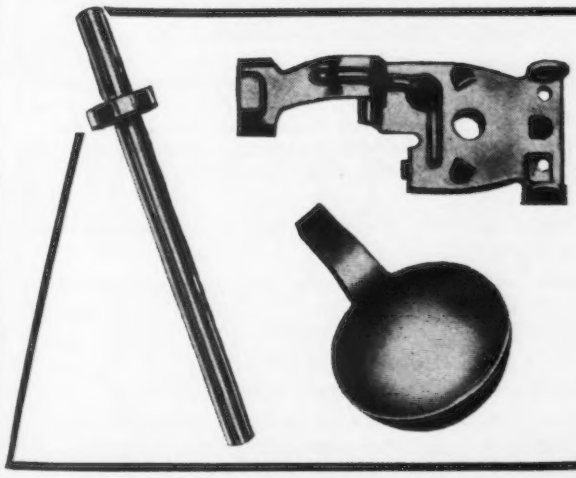
WHICH **Stainless Steels** for these parts?

● The answer to selecting the proper Stainless grade for a specific job requirement may depend upon any of a dozen factors—fatigue strength, lighter weight, corrosion resistance, heat resistance, easier fabrication, etc.

And that is one reason why many designers and production men are turning to Carpenter for help with their Stainless design and fabricating problems for product improvement and cost reduction. Carpenter has long been their general headquarters for useful information about Stainless Steels.

How many ways are there for you to profit through our diversified experience in solving Stainless problems? Need fabricating assistance, or data on the corrosion and scale resisting properties of various types of Stainless Steel?

Or could you make use of personal assistance in the shop? If so, get in touch with your nearby Carpenter representative. You may be able to use his experience to lick a tough design problem, or simplify production methods to increase plant output. You'll certainly find it worthwhile to have a chat with him to discuss your Stainless Steel requirements.



It takes a wide range of Stainless properties *for the economical production of ladles for non-ferrous metals, switch parts and valve stems. The ladle must resist high temperatures, while the switch part is made from ductile Stainless Strip that makes possible intricate shapes and sharp bends. And still another Stainless is used for the long-wearing valve stem.*

The Carpenter Steel Company, 121 W. Bern Street, Reading, Pa.

Washington

L. W. MOFFETT

• Socialized business battle not started yet ... Europe believed going economically left ... Agricultural agreement sets pattern for program ... Anti-trust laws can be by-passed.

WASHINGTON—The real battle between the conflicting concepts of socialized and private business has not even begun.

Preliminary skirmishes in the form of speeches and articles by private enterprise proponents have not yet touched the real issues that involve the fact that the machinery for socializing business is in existence, and that America will indeed have a hard time escaping socialism.

In this country there will be a great deal of resistance to more bureaucracy, more regimentation, and more planned economy. The Justice Department is relying upon the traditional American hatred of monopoly and pioneer principles of government and economics in its fight on cartels.

But the proponents of socialized business say that the last depression is proof that private enterprise has failed, that America has reached the crossroads where it must choose between international economic cooperation or economic isolationism.

Socialized "businessers" say that if the United States chooses the road of economic isolationism, socialization of industry will come quicker because of the demands of those who insist upon "full" employment which cannot be satisfied without setting up an internally planned economy. Furthermore, this philosophy says that international commodity or cartel agreements will stave off the degree of business control which will be necessary to gain "full" employment domestically, but that business must look for socialization either way.

WHO are these men? They are prominent individuals throughout the government. In the State Department, the Foreign Economic Administration, Congress, WPB, and the Commerce Department the thought is that even if private enterprise is not through in this country on account of its failure, and they are sure it has failed, the pressure of all foreign socialized economies after the war will prevent its continuance.

Competent business observers say that Europe is going to the left economically after the war because of the mighty influence of Soviet Russia. To Europeans, they say, victorious Red armies are proof that the Russian system cannot be so bad, and this will be a cogent argument to Europeans who may look to Russia for postwar help. It is considered inevitable that the ideas of socialized industry which already had a good hold on the continent will be spread further.

The British have told the United States flatly that unless this country enters into international commodity agreements with them, cartelize our foreign and domestic trade, and repeal our anti-trust laws, they will be forced to join with continental governments in a World Trade Alliance excluding the United States.

While the threat of economic sanctions is more irritating than fear-producing, the idea of being on the outs commercially with all the rest of the countries of the world has little attraction to cartel proponents. United States industry could compete with the rest of the world, but government would have to subsidize exports to maintain export volume, they say, and this would bring on socialization of business anyway.

The machinery for doing this is in existence. There is even a precedent for doing it in the wheat and sugar agreements entered into by the Department of Agriculture.

THESE agreements are pure cartels formed under the umbrella of close governmental supervision. Export quotas are set and penalties are provided for exceeding quotas, for importing from sources not sanctioned by the agreement, and for exceeding prices fixed by the agreement.

Congress approved the treaty permitting the formation of the agricultural cartels and consequently the Department of Justice is powerless to proceed under the Anti-trust laws. Moreover, if similar agreements were entered into with respect to steel, bearings, consumer electrical goods, or other commodities, the Clayton and the Sherman Acts would be by-passed.

The United States government proponents of cartelization point out that WPB with all of its regulations would have to be made a permanent part of the government. The Combined Raw Materials and the Production and Resources Boards would also be made permanent, and merged.

Industry advisory committees would be strengthened even as the Baruch report recommends, with representation granted to even the small producers. These committees would become trade associations, under the

DRAMATIC BREAK: *In bitter protest against the President's veto of the tax bill, Senator Alben Barkley (D.-Ky.) resigned Feb. 23 and is shown walking alone from the Senate Office Building. He was re-elected majority leader later last week.*

ANNOUNCING
A New Refractory Service

Gunmix Gun, Model No. 1, designed to apply Gunmix to hot basic brick sidewalls in electric steel furnaces.

GUNMIX ...a unique refractory and a pneumatic gun for emplacement by air stream and water

● In Gunmix and the Gunmix Gun, Basic Refractories, Inc. offers another contribution to the art of refractories.

The Gunmixes—a series of basic, acid and neutral refractories designed for emplacement by air stream and water—represent just as great a departure from conventional refractory practice as was introduced 5 years ago with Ramix, the cold-ramming basic hearth refractory.

Gunmix refractories have these distinctive, outstanding properties:

1. High refractoriness.
2. Rapid coalescence with hot surfaces.
3. Ready adherence to vertical walls.

Gunmix Guns are specially designed for particular uses, with these features: simple design for ease of operation, low cost and maintenance.

The first Gunmix refractory, now in successful use, is a basic refractory intended primarily for maintenance of basic sidewalls of electric steel furnaces. Gunmix Gun Model No. 1, illustrated above, has been designed for this particular application. Other models will follow.

Many months in development, these new Gunmix refractories give promise of wide application in furnaces of many types. Your interest and your suggestions as to other possible uses for Gunmix will be welcomed.

plan, and would provide the industrial know-how in making international agreements.

The Combined Production and Resources Board and the Combined Raw Materials Board would be thrown open to membership of all foreign countries, to form an international agency with powers to approve and amend such commodity agreements as might be entered into. The Boards would probably have strong State Department, WPB, and Commerce Department supervision.

Thus, the Department of Justice objections to cartels that they are private international agreements, affecting the entire public interest and mostly adversely during the war, would be overcome. The commodity agreements would be constantly under the government's eye.

THE Anti-trust laws would become a dead-letter. The combinations which have been formed during the war under exceptions to the Anti-trust laws would be permissible for all time after the war wherever advantageous.

It is generally conceded that at no other time in history has there been so wide-spread a concentration of industry, as has been fostered by the government during this war.

This concentration was thought necessary to obtain maximum war production. With conversion, the automobile, aircraft, electrical manufacturing, small arms ammunition, and a host of other industries, exchanged material, dies, tools, jigs, patents, methods, and even shared management skills. Everything short of actual merging of corporate identity has been done.

The formation of WPB brought together in the various industry divisions executives of all the competing parts of the different industries. And while these dropped their industry connections for the duration to serve the government's interest, the effect of their association might well further the cause of postwar concentration and combination of companies.

The industry advisory committees, together with the trade associations, have worked together in mobilizing America for war. Mr. Baruch has recommended that they assist in demobilizing America for peace. In this, WPB chairman Donald M. Nelson has publicly agreed.

Yet, both Mr. Baruch and Mr. Nelson are said to be opposed to the formation of cartels for transacting postwar businesss.

Which way are the dice going to fall?

Contract Termination Clause Amended

Washington

• • • **The Office of War** Mobilization uniform contract-termination clause for fixed-price war contracts, issued Jan. 8, was amended Feb. 24 to specify instances in which the contracting agency may elect not to use the article. The original directive conceded that there were instances where the uniform termination could not be applied and asked government officials to report any such instances. Study of such reports submitted prompted the inclusion of eight types of commitments on which exceptions will be permitted. These are:

1—Contracts for amounts less than $50,000 regardless of delivery date.

2—Contracts for amounts less than $500,000 providing for delivery within six months.

3—Letter of intent and other preliminary contractual arrangements that contemplate subsequent execution of form contracts.

4—Contracts of government departments, agencies, and instrumentalities of the government with states or subdivisions of instrumentalities thereof.

5—Contracts for purchase of material manufactured as a by-product or a co-product in an integrated operation from common raw material source in such manner that the cost of its manufacture is not susceptible of separate determination.

6—Contracts made in the name or on behalf of the government by contractors under a cost or cost-plus contract with the government for materials, supplies, or equipment required in construction of government-owned plants or facilities.

7—Contracts including pool orders and commitment contracts for production that provides that complete items produced under the contract and furnished to the government shall be paid for at a price intended to exclude profit.

8—Requirement or open contracts.

The uniform contract-termination clause allows full payment at contract price for all articles completed by the contractor on termination date and limits to 6 per cent the profit on articles begun but not completed. The articles of the clause will be used by governmental agencies and departments in all contracts executed more than 30 days after the publication of the article and accompanying article by the particular department or agency. The publication of these is to be as soon as practicable.

THE BULL OF THE WOODS — BY J. R. WILLIAMS

Checks INTERNAL AND EXTERNAL DIMENSIONS

To MILLIONTHS of an Inch

UNUSUAL FEATURES FACILITATE FAST AND ACCURATE OPERATION

Model N-4 Internal-External Measuring Instrument is an entirely new Sheffield development for Toolroom and Gage Laboratory use in checking master and working gages, setting snap gages, etc..

- Checks internal dias. of ¼" to 12".
- Checks 3" max. depth of hole, 1 side.
- Checks external dimensions up to 12".
- Gaging arms elevated electrically.
- Indicator automatically shows height of gaging arms.
- Signal lights facilitate setup.
- Positive electrical magnification of 2500 to 1 with Electrigage.
- Linear scale of .012" range graduated in 50 millionths.

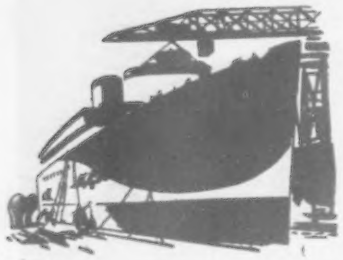
MACHINE TOOLS • GAGES • MEASURING INSTRUMENTS • CONTRACT SERVICES

WEST COAST . . . OSGOOD MURDOCK

• Over 500,000 tons of steel a month now rail-hauled transcontinental . . . Geneva supplies plentiful foundry pig, but no plates before April . . . 43% of aircraft workers now women.



LOS ANGELES—Seven inches of tropical cloudburst drenched southern California, washing out bridges and highways and causing the ten-hour Daylight train to reach San Francisco 18½ hours late one day last week.

Col. Rufus W. Putnam for the Army Engineers took over management of the local municipal Department of Water and Power by order of President Roosevelt after a 10-day strike of 2500 AFL linemen, dispatchers, and service electrical workers, climaxed by flood damage and utility disruption, was shutting down air craft and warplants and demoralizing this metropolitan area.

On the tip of a patriotic independent service station operator in San Francisco, OPA investigators uncovered 640,000 counterfeit C-2 gasoline coupons, each good for five gallons, at a single private address. The long overdue sleuthing and investigation which is in progress uncovered black market and counterfeit operations on a grand scale, and fumbling, incompetence and lack of system or vigilance on the part of OPA rationing officials.

Such were the types of incidental distractions which last week impeded the well-known war effort and piled new complications on the overtaxed and harried transportation, housing, food and willing worker supply of West Coast industrial areas.

Pointing up again the staggering heavy materials load that the war has placed on western rail carriers is a tabulation from Interstate Commerce Commission records which show the iron and steel movement by seven principal rail lines serving the West Coast. Total figures are included for Southern Pacific's Lines, Union Pacific, Western Pacific, Santa Fe, Northern Pacific, Great Northern and the Spokane, Portland and Seattle, a joint operation of G. N. and N. P. between Spokane and Portland, and Portland and Seattle. These seven systems moved a total of 1,642,965 net tons of iron and steel classification products in 1940. Of this total 36 per cent was over the Southern Pacific, 22 per cent Santa Fe, 18 per cent Union Pacific and the remaining 24 per cent over the four other lines. The revenue for hauling this total tonnage was $9,715,608, or an average of $5.92 per ton hauled.

In 1942, two years later, the aggregate tons of iron and steel class products hauled had increased to 8,109,972 tons, a five-fold multiplication. In two years these rail lines were not only hauling five times the iron and steel tonnage but they were hauling each shipment two-thirds as far again on an average, as evidenced by the increased revenue per ton.

Of the individual carriers, Southern Pacific, Santa Fe and Northern Pacific quadrupled their gross tonnage. Union Pacific and Western Pacific handled six times their former tonnages and Spokane, Portland and Seattle hauled 12 times its earlier traffic. Great Northern's burden was five times increased.

When the figures for 1943 are finally tabulated and available, they will show additional staggering volume and still rising crescendo.

There are duplications in these tables, when freight was hauled by one of these seven carriers part way and turned over to another for the remainder of its routing. Traffic experts therefore figure that the carriers transported approximately 5,000,000 tons of iron and steel to Pacific Coast ports in 1942. Shipments averaged 42 tons to the car, to aggregate 1700 trains of 70 cars each, or nearly five trains per day, all in one direction.

During 1936 and 1937 iron and steel tonnage transported through the Panama Canal averaged 1,250,000 tons to Pacific Coast ports. The rails have therefore taken up all this "normal" tonnage and are carrying also the raw materials for new production on the West Coast as well as finished products for shipment trans-Pacific for Army, Navy, and general military and commercial supply.

FOLLOWING release of pig iron from allocation restrictions since February 1, West Coast foundries have been supplied with excellent quality foundry pig at ceiling prices from the Fontana and Geneva furnaces. Geneva No. 1 furnace has produced a steady 600 tons per day since Jan. 3 and No. 2 is now producing 400 to 500 tons per day. Nearly all first run is being sold for foundry use throughout the Intermountain and Pacific Coast area, the first provident domestic supply of pig ever available in this area.

It now looks like plates some time in April to those familiar with erection and installation progress at Geneva. Motors and cranes, which were holding up installations six months ago, are on hand as scheduled, but Mesta mill equipment is now the limiting factor.

THE aircraft atmosphere in southern California these days is clear and tonic. February production of the West Coast aviation industry is going to be up, way up, according to unofficial though authoritative predictions by those in a position to know.

Women continue to carry an increasingly important burden in maintaining and accelerating production. By the close of 1943 women constituted 43 per cent of the total production personnel of Pacific Coast aircraft plants. Average monthly employment of women in 1942 was 45,714, but by the first of the current year a total of 113,870 women workers were enrolled.

Even when 53.3 per cent of Douglas employees at Santa Monica voted for no union and 46.7 per cent voted for the CIO United Auto & Aircraft Workers in the recent run-off election, the issue apparently was not finally decided. This is Douglas' biggest plant, the original home plant, with well over 40,000 employees, the largest single aircraft operation on the West Coast. It is reported that 90.3 per cent of the eligible production employees voted. Comparison of the

Harden it for 10¢ with TOCCO

PROGRESSIVE *Kearney & Trecker Corp.*, Milwaukee, Wisc., reports the following savings by TOCCO hardening the above saddle clamp eccentric of their Milwaukee Milling Machine:

	FORMER METHOD	TOCCO
Heat treating	$ 0.721	$ 0.099
Straightening	0.752	0.000
Cleaning	0.100	0.000
Total Cost	$ 1.573	$ 0.099

Saving . . . $1.47 per piece

In addition to this saving of $1.47 per piece, TOCCO made possible a switch from alloy steel to S.A.E. 1045 steel, saving $0.110 in material cost per piece.

Total saving on each run of 1375 pieces for this one part is $2,172.50.

Kearney & Trecker hardens a total of 138 different parts on one "TOCCO JR." machine. Output of some parts has been increased as much as 500%.

Output of the saddle clamp eccentric was boosted 144%—from 41 to 100 pieces per hour!

Why not enlist TOCCO's experienced Engineers to help you obtain similar improvements for *your* production? New booklet, "Results with TOCCO", free on request.

THE OHIO CRANKSHAFT COMPANY • Cleveland 1, Ohio

HARDENING..BRAZING
ANNEALING..HEATING
★

vote in the final run-off with the election a week earlier indicates that a little over half of the 26 per cent who originally voted for AFL were for no union in the finals and only 47.7 per cent of the original AFLers were willing to be represented by CIO. Demand for a new election and charges of unfair conduct of the run-off have been filed with the NLRB by CIO.

CIO United Auto & Aircraft Workers point with pride to the new contract signed at the Douglas Vernon plant which they state is the best in the industry, guaranteeing merit wage increases, reviewing wages automatically every 16 weeks, providing an eight cent per hour shift differential and providing against discrimination.

At Consolidated - Vultee in San Diego, 74 per cent of the 7000 eligible white collar salaried employees voted as to whether the AFL Machinists would represent them, and 50.3 per cent were for the union, so that it became the bargaining agent by as narrow a squeak as is conceivable.

The first all-welded steel car barges ever built in the Puget Sound area have been launched at Olympia, for the Puget Sound Navigation Co. The barges were 100 per cent completed before launching. They are 264 ft. long by 42 ft. abeam. Each barge has three tracks and will haul 15 railroad freight cars at a time.

Now that 1943 aircraft production figures are all in and carefully computed, Aircraft Production Board has officially congratulated Consolidated Vultee Aircraft Corp. for having delivered more airplanes by number and weight than any other manufacturer. Convair's deliveries totaled more than 126,000,000 lb., including spares, compared with 115,000,000 lb. delivered by the second largest and 73,000,000 lb. by the third largest producer. The Consolidated contribution to total production was 12 per cent by number and over 16 per cent by weight. It further developed that the San Diego division of the company has the nation's highest output per man per day in the production of heavy bombers with an average of 8.2 lb. per man day. The national average was only 4.6 lb. and the second most efficient producer was 5.8 lb.

Steel Tight Through 2nd Quarter, Says WPB

Washington

• • • **While steel** is much easier and in adequate supply to fill all essential requirements, it will continue tight for the second quarter, according to WPB. This is the information now being given architects and engineers. They are being advised, however, that in designing new projects it would be more economical to use steel than to require the use of lumber.

Due to specific programs, it does not appear that there will be any easing of the steel situation generally until the third quarter.

With the demand centered on ship construction, plain structural materials deliveries have lengthened slightly to other buyers, including warehouses, although some tonnage is available in late March. This is due to pressure for steel for landing craft and may ease slightly next quarter. This is a possibility that first quarter shipments may be advanced somewhat, although this is dependent largely on the ship program, inasmuch as it is now impossible to validate any substantial construction project on which steel could be shipped before April.

Structural steel framing (except plate girders) may be permitted for buildings in which it would be the logical material to use. In general this is the case when the roof span is in excess of 40 ft. and the floor span is in excess of 25 ft. The structural steel designer is expected to develop designs requiring the least amount of material consistent with safe practice. When obtainable, used steel or steel available in idle or excess inventories must be used. Such steel is not a controlled material.

Nelson Report Shows Air And Land Craft Increases

• • • **Combat aircraft** and landing barges output showed a substantial increase for January along with other war equipment, according to a report by Donald M. Nelson, WPB chairman, on Feb. 23. The over-all production index, however, showed a 2 per cent slump from December to January.

The number of landing craft accepted for service rose 20 per cent in January. The number of planes accepted, however, fell from 8802 in December to 8789. Deliveries of merchant vessels fell off 40 per cent; guns and fire-control equipment were down 8 per cent; ammunition was down 6 per cent, and combat and motor vehicles were down 17 per cent in comparison with December. This program has been designed to slow down, but output of heavy trucks, which fell sharply below December levels, was disappointing. Completed war and navy-built vessels totaled 298,000 displacement tons, compared with 343,000 tons in December.

Industry Advisory Committees

• • • **WPB on** Feb. 21 announced the formation of the Rolls Royce Merlin Aluminum Casting Industry Advisory Committee. Stanton W. Ballard, WPB Aluminum Division, has been appointed the government presiding officer. The membership is as follows:

D. W. Bay, Aluminum Alloys Corp., Detroit; Bruce Burroughs, National Bronze and Aluminum Foundry Co., Cleveland; N. Harold Boardman, Elmira Foundry Co., Elmira, N. Y.; B. A. Dollens, Delco-Remy Corp., Anderson, Ind.; L. D. Harkrider, General Malleable Corp., Waukesha, Wis.; Frank C. Howard, Howard Foundry Co., Chicago; Ed P. Haas, Metal Parts Corp., Racine, Wis.; Fred Maytag, II, Maytag Co., Newton, Iowa; Harry L. Smith, Aluminum Co. of America, Cleveland; Arthur B. Schnell, Aluminum Industries, Inc., Cincinnati; R. J. Roshirt, Bohn Aluminum and Brass Corp., Detroit; M. E. Van Riper, National Foundry and Machine Co., St. Louis; and Karl A. Stein, Acme Pattern and Tool Co., Dayton, Ohio.

PERSONALS

• **D. M. Sheaffer,** Philadelphia, and **William A. Alfs,** Detroit, have been elected the new directors of International Detrola Corp., Detroit.

• **Harvey T. Hill,** has recently been appointed executive director of the Diesel Engine Manufacturers Association with headquarters in Chicago.

• **E. B. Scott** has been appointed to the position of sales manager of the engine division of the Enterprise Engine & Foundry Co. Prior to his promotion, Mr. Scott was manager of the repair and maintenance division.

• **Gordon K. Tollaksen** has been appointed purchasing agent of the Dumore Co. of Racine, Wis., to succeed **J. M. Hamilton.** Since June 1942, Mr. Tollaksen has been assistant purchasing agent.

• **C. G. Wollaeger,** who has been connected with war production for Milcor Steel Co., Milwaukee, has been made vice-president in charge of sales. He joined Milcor in 1926.

• **Fred T. Goes** has been elected president of the Vilter Mfg. Co., Milwaukee, succeeding the late William O. Vilter. **William B. Vilter,** has been made vice-president to succeed Mr. Goes and will continue as director of personnel. Other officers elected were **E. B. Tilton,** executive vice-president and treasurer; **E. F. Vilter,** secretary and **W. H. Wenzel,** assistant secretary.

• **W. H. Grinold** has been elected vice-president in charge of operations and **G. J. Griffin** vice-president in charge of sales of the Wallingford Steel Co., Wallingford, Conn.

• **A. H. Kean** has been made general manager of the Edward A. Lynch Machinery Co., Ardmore, Pa. He was previously with the Bridgeport Safety Emery Wheel Co.

• **J. B. Ribakoff** has been elected president of Reliance Steel Corp., succeeding **Sol Friedman,** who resigned as president and treasurer and disposed of his interests in the company. **Philip P. Brown** has been elected executive vice-president, and **I. R. Zwick,** treasurer.

• **Carryl A. Asher,** eastern sales manager and a vice-president, has been elected a director of Electro Refractories & Alloys Corp., Buffalo. He will continue to have headquarters at New Haven, Conn.

• **Philip H. Clapp** has been appointed abrasive division district manager for the Pacific coast by Norton Co. He will make his headquarters in Los Angeles. Mr. Clapp has been with Norton for 30 years and since 1935 has been district manager in Detroit.

• **E. M. Whalley** has been promoted to works manager of Pesco Products Co., Cleveland, a division of Borg-Warner; **Louis Matthews** to general superintendent; **Jay M. Roth** to director of engineering of pump and automotive departments and **John A. Lauck** to chief engineer of the pump department.

• **Vincent A. Sheals** has been appointed designing engineer of the cable engineering division of General Electric's Schenectady works, N. Y. **W. C. Hayman,** Mr. Sheals' predecessor, will be available as a general consultant.

• **Ray J. Cowden** has been appointed sales manager of Lycoming division of the Aviation Corp., in Williamsport, Pa. Mr. Cowden for the past two years has been contract and service engineer at the American Propeller Corp., Toledo, a subsidiary company.

• **C. B. Allen** has been transferred from Washington to the Detroit district of the Reliance Electric & Engineering Co., Cleveland, as an application engineer.

• **N. I. Mekell, Jr.,** formerly assistant manager, has been appointed manager of the grating department of Blaw-Knox division, Blaw-Knox Co., Pittsburgh. He succeeds **Elmer E. Brodhead,** former manager. Mr. Mekell in the past was a manufacturer's agent for steel products in the eastern zone.

• **Lyman D. Warner** has been appointed sales manager of the Crocker-Wheeler division, Joshua Hendy Iron Works, Ampere, N. J.

• **A. H. Freeman** has joined R. L. Orth in representing the American Foundry Equipment Co., Mishawaka, Ind., in the Detroit territory, filling the post vacated by the death of M. T. Mortensen.

• **L. A. Ver Bryck** has been made New York district sales manager for Pittsburgh Steel Co. Mr. Ver Bryck has been the company's Washington, D. C. sales representative since 1942. **W. F. Boore** has been made assistant manager of sales, Steel & Wire Products, at the company's general office in Pittsburgh. **J. G. Smith** has been made district sales manager at the Pittsburgh district sales office and **W. J. Meyer** will assist Mr. Ver Bryck.

• **R. C. Edgar** has been appointed personnel director of Allegheny Ludlum Steel Corp. He will have general supervision of all industrial labor relations, employment, safety and welfare departments.

W. J. FISHER, president and general manager of A. B. Farquhar Co., formerly A. B. Farquhar Co., Ltd.

R. C. EDGAR, personnel director, Allegheny Ludlum Steel Corp., Pittsburgh.

• **P. L. Dafoe,** who has been on leave of absence from his position as manager of the central division of Acme Steel Co., Chicago, has resumed his post after spending 15 months in the tank, automotive center office of the Chief of Ordnance, Detroit.

• **H. S. RuDesill,** for many years sales representative in the Detroit office of Rustless Iron & Steel Corp., Baltimore, has been appointed district manager.

• **E. C. Hetherwick** has been named vice-president and general manager of Haye Industries, Inc., Jackson, Mich. and will continue as treasurer. **William J. Donahue** was elected secretary and assistant treasurer.

• **J. J. Donovan** has been named regional manager of the Chrysler Airtemp New York office. Mr. Donovan will direct Airtemp sales and service activities in the greater New York area and New England. Since 1941 he has been associated with the WPB.

• **A. D. Robertson** has been appointed assistant manager of the motor division of Allis-Chalmers Mfg. Co. at its Norwood works, Norwood, Ohio.

• **F. G. Gepfert** has been elected chairman of the board of Black Industries, Cleveland, which is comprised of Black Drill Co., Black Boring Machine Co. and Mec-Rad Co. Consolidation of all executive offices has been made in the company's new building located at 1400 E. 222nd St., Cleveland.

• **T. C. Knudsen** has been named manager and chief engineer of the new Texrope department established by Allis-Chalmers Mfg. Co., Milwaukee.

• **Bert Conway** has been named vice-president in charge of manufacturing of the Aviation Corp. Mr. Conway's headquarters will be in Detroit.

• **W. F. Vosmer,** until recently an executive in the steel section of WPB in Washington, has rejoined Republic Steel Corp. as manager of railroad sales. In this post Mr. Vosmer succeeds the late **Emmett Conneely.**

• **T. B. Hale,** former domestic sales manager of International Harvester Co., Chicago, has been elected vice-president of general line sales, and in that capacity will supervise the operations of a newly designated general line sales department. **F. W. Jenks,** former manager of the company's credit and collection department, has been elected vice-president of merchandising services. Four new divisional heads under the new company setup are **R. C. Archer,** general manager, farm tractor division; **R. P. Messenger,** general manager, farm implement division; **H. T. Reishus,** general manager, industrial power division and **Neil Loynachan,** general manager, fibre and twine division.

Harvester also has promoted **M. J. Graham** from manager of manufacturing to assistant to the vice-president in charge of manufacturing; **A. J. Peterson,** formerly assistant manager domestic sales, to manager of the general line sales department and **F. B. Mattingly,** to manager of the credit and collection department.

• **Charles W. Olsen,** for 33 years district manager for the Carpenter Steel Co. at Hartford, Conn., will retire shortly. Mr. Olsen has completed 49 years of active service with the company. He is succeeded by **Wynn F. Rossiter,** who for 20 years has been associated with him on the New England staff of the Carpenter Steel Co.

• **James E. Sweeney** has been elected vice-president and director, and **Howard Hall,** a director, of Kropp Forge Co., Chicago. **Raymond T. O'Keefe, Jr.** has been elected vice-president of Kropp Forge Aviation Co.

F. G. GEPFERT, chairman of the board of Black Industries, Cleveland.

WYNN F. ROSSITER, district manager at Hartford, Conn., for the Carpenter Steel Co.

OBITUARY...

• **John F. Mitchell,** one of the organizers of the Mitchell Mfg. Co., Milwaukee, died Feb. 12 at his home there after a year's illness at the age of 67.

• **George E. Phillips,** general superintendent of production planning and control for Chevrolet Motor Division, Buffalo, died Feb. 12 at his home in Kenmore, N. Y. He was 51.

• **A. Edmond Park,** president of Flint & Walling Mfg. Co., Inc., died on Jan. 24.

• **George W. Thornburg,** founder of the Crescent Park Brass Foundry, Waltham, Mass., died recently. He was 64 years old.

• **Raymond M. Hughes,** assistant chief engineer of Great Lakes Steel Corp., Detroit, died recently. Before coming to Great Lakes Steel in 1929, Mr. Hughes worked for Youngstown Sheet & Tube Co., Republic Iron & Steel Co., and Trumbull Steel Co. of Warren, O.

• **Jesse J. Ricks,** chairman of the board of Union Carbide & Carbon Corp., died at his home in Plandome, N. Y., on Feb. 20, after a brief illness. He was 64 years of age. Mr. Ricks became chairman in 1941. He had been president from 1925 to 1941.

• **Samuel J. Reeves** president of the Phoenix Iron Co., Phoenixville, Pa., was killed in an automobile accident Feb. 18. He was 64 years old and a graduate of Yale University.

• **John J. Flanagan,** 50, vice-president and treasurer of National Mfg. Corp., Tonawanda, N. Y., died Feb. 18 in Chicago. His home was in Buffalo.

Fatigue Cracks . . . .

BY A. H. DIX

Draft Fodder

• • • "Why," we asked a manufacturer sitting opposite us in the diner the other night, "do so many defense plants seem to have so many more men than they need for the work?"

"Draft fodder," he said. "You hire a lot of extras so that in complying with your replacement schedule your basic working force won't be touched."

Retreat to the Farm

• • • With that out of the way we jumped to our other favorite topic of conversation. "What do you think would be the least painful way of scaling down the probable 300 billion dollar postwar debt bunion so that we can get our postwar feet into our postwar shoes?"

"I'm buying a little place upstate," he said.

Stopper

• • • "We make the Damnedest Looking Things! — *American Spring of Holly, Inc., Holly, Mich.*

If this company's telephone operator gets a cold in her head we hope it comes in December, as it would add to the Christmas spirit if she said, "This is Abericad Sprig of Holly."

Mine Host's Megalomania

Speaking of the craze for plurals, when I was in the Washington Statler hotel the other day the top item on the "Today's Events" bulletin board read, "War Manpower Commission—Continental Room."

—*E. O. Schott*

Audience Agog

• • • As a loving reader you will share our joy in learning that even though the number of publications fighting for a share of your reading time is greater today than ever before, our anemometer indicates that reader interest in your favorite family journal is right now at full gale proportions.

We suppose we will have to credit much of this to the brains department's cleverness and industry. But at least an honorable mention should be given to the fact that changes are so frequent that you can't keep your eyes off the scoreboard for even a week without running the danger of missing a play that completely reverses a given situation.

It would be untruthful to say that we do not still find people who are too busy to read and who will spend two hours proving it to you. But on the whole the big, more or less happy family is watching with record-high raptness the bulletins teletyped in from strategic points by the brains department's pulse-feelers.

Left Hand Drill

• • • Latest chapter in what is now a *cause celebre* — the left hand "drill" in the "Bull of the Woods" cartoon of Dec. 9 — is written by Richard F. Cleary, general manager of Strait & Richards, Inc., Newark 8, N. J.:

Those who say it is a helical taper pin reamer may have your technical editor, Frank Oliver, out on a limb, but the cartoonist, J. R. Williams is still stuck with a left hand drill, for the caption reads, "Here's a ***drill*** and here's a piece of iron—you just ***drill*** a hole in it. There's a million of 'em and a war on."

Or else he proposes to "drill" a million of 'em with a helical taper pin reamer and with a war on.

J. R. Williams started it and we will let him finish it. A clipping of this page is being sent him with a request to let us know why he drew the flutes running counterclockwise.

No Torch Carrier

• • • Mr. Williams is a machine shop veteran and his reason will doubtless be completely satisfying. But not all cartoonists are technically well-heeled. Take, for example, the cartoonist who illustrated the Grape Nuts Flakes advertisement on page 58 of the Feb. 26 *Saturday Evening Post*. "A pert little welder named Susie" has a hammer in one hand and a wrench in the other.

Torpedoed

• • • The Feb. 3 editorial ended up, "It will have been, as the saying goes, 'spurlos versank.'" Our friend Ingo Maddaus wrote that it should be *spurlos versenkt*. We said our German grammar held its hand over the head of *versank*. He says:

You looked up the wrong verb in **sinken**. In German the verb "to sink" has three equivalents, each with a different shade of meaning: **versenken, versinken, sinken.**

In English the last three words of the editorial would have been "sunk without trace," the German equivalent of which is **spurlos versenkt.** My authority is "Duden, Rechtschreibung der deutschen Sprache," a grammatical textbook in all German schools."

We say "Kamerad!"

Air Castle Bomber

• • • Thanks to a system devised by Oliver L. Johnson, the scholarly, fact-worshipping head of your favorite family journal's Department of Research, our editors know almost as much about you as the editor of a country newspaper in a 1000 pop. town knows about his readers.

He does it with punched cards — one for every subscriber. There's a hole for class of product, another for financial rating, others for kinds of operations, and so on.

This passion for exactness, while probably all right in its way, has robbed us of the fuel that warmed many a pleasant half hour's argument. If an editor ran across something hot on say pickling, we could spend at least thirty minutes discussing the extent of the audience. Now we have no excuse. It's exactly 18.3 per cent.

And two out of five do heat treating, better than half do production welding, 97 per cent have machine shops, two out of eleven do electroplating. In talking to a lacquer manufacturer an advertising ambassador of ours could paint a seven-color picture of the number of metal products makers who paint or lacquer their products. Now he is hogtied to a black and white 47 per cent.

We suppose that Johnson has pushed industrial journalism another square closer to the king row, but at the cost of a lowered wing flap on the flight of fancy.

Puzzle

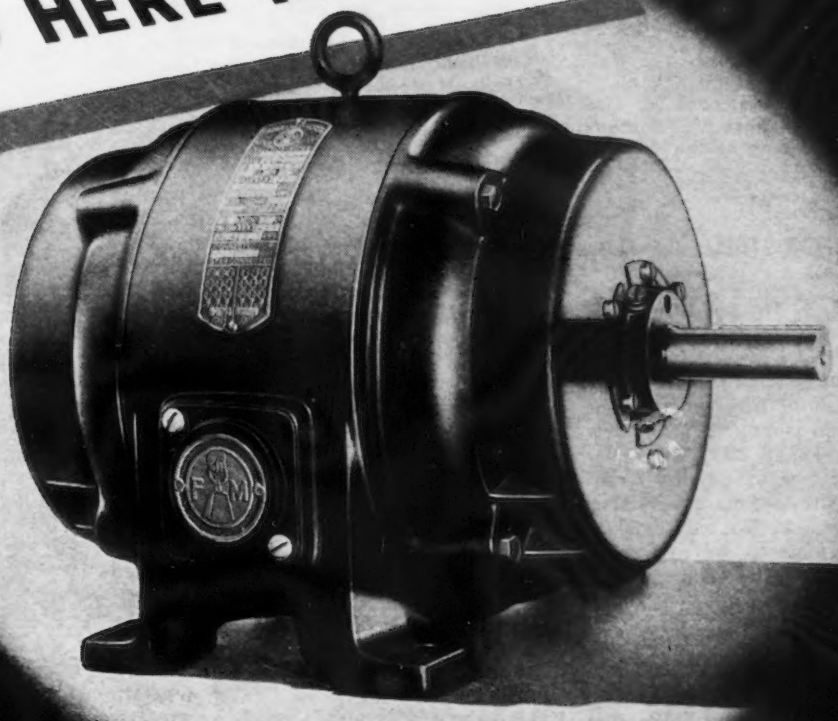
You can arrange last week's 3 nines to equal 20 this way: $\frac{9 - 9}{.9}$

Guy H. Colony complains about the answer of 18 days to the problem about the 21-ft. well with a frog that climbed 3 ft. each day and slipped back 2 ft. each night. On the 18th day he climbed 3 ft., bringing him up to 21 ft. He wrapped his front legs around the lip of the well so he couldn't backslide, and that was that.

Two minutes should do for this:

Stations A and B are 120 miles apart on a single-track railroad. At the same instant that a train leaves A for B at 25 m.p.h., a train leaves B for A at 15 m.p.h. Just as the first train leaves A, a fly flies from the front of the engine straight toward the other train at 100 miles an hour. On meeting the second train it immediately turns back and flies straight for the first train. So it continues to fly back and forth with undiminished speed until the collision. How far did it fly?

TOMORROW'S MOTOR IS HERE TODAY!



WITH *Copperspun* ROTOR

YOU can buy this new postwar designed Fairbanks-Morse motor now—*knowing* that it will be just as modern—just as efficient—just as up to the minute in years to come as it is today.

It is indeed a challenge to the future—in efficient motor design.

- It is a 40°C. motor.
- It is a protected motor!
- It has the most adaptable, convenient, and handiest conduit box you ever laid your eyes on!
- It has the famous Fairbanks-Morse COPPER-SPUN Rotor!

Important!

Never before has there been more stamina—more protection—more versatility built into a motor housing. A demonstration is necessary to fully appreciate how much this motor can really offer you. See it and judge for yourself.

Dear Editor:

HIGH SPEED MILLING

Sir:

In what issue did your article "High Speed Milling" appear?

A. M. HARRINGTON,
Treasurer
Harrington Co.,
17th & Callowhill Sts.,
Philadelphia 30

● Oct. 14, 1943, issue, page 74. See the Dec. 9, 1943, issue, page 75, for the report of the ASME meeting on this subject.—Ed.

NO GLUE FOR STEEL

Sir:

Your Jan. 27 Dear Editor page reported that the United States Plywood Corp., New Rochelle, is a source of a glue for gluing steel to steel.

As a result of this remark and an earlier similar comment in the Oct. 21, 1943, issue (page 33), we have received a flood of inquiries from all over the country. This is very flattering to IRON AGE, but extremely embarrassing to us as we are not prepared to furnish any such glue or adhesive. . . .

CHARLES B. HEMMING,
Chief Chemist
United States Plywood Corp.,
Beechwood Ave., Second St.,
New Rochelle, N. Y.

● Our apologies to United States Plywood Corp. for placing it among those manufacturing metal-to-metal glue. Two correct sources are U. S. Stoneware Co., Akron, Ohio, and B. B. Chemical Co., Cambridge, Mass.—Ed.

MACHINE HYDRAULICS

Sir:

In your Feb. 17 Dear Editor page, Knox A. Powell, of Minneapolis-Moline Power Implement Co., inquired for a textbook on the operation, maintenance and repair of hydraulic systems as applied to machine tools.

The Henry Ford Trade School, Dearborn, Mich., has compiled and published a very complete book entitled, "Hydraulics As Applied to Machine Tools." The cost is 75c. Orders, accompanied by payments, should be sent to the School.

To my knowledge this is one of the most complete books on the fundamentals, maintenance and repair of hydraulic pumps, accumulators, intensifiers and special control valves that has ever been compiled for shop use.

H. C. SPROULE,
Hydraulic Sales Engineer
Lake Erie Engineering Corp.,
727 Nicholas Bldg.,
Toledo 4, Ohio

BERYLLIUM COPPER

Sir:

Please send us three reprints of H. G. Williams' article, "Predicting Spring Performance of Beryllium Copper Wire and Strip." This appeared in your July 8 issue.

O. O. BROPHY,
Engineer
American Mining & Research Co.,
Eagle and Lawrence Rds.,
Upper Darby, Pa.

● Reprints can be obtained from H. G. Williams, Instrument Specialties Co., Little Falls, N. J.—Ed.

BORON ELECTRODES

Sir:

Your Feb. 3 issue has a very interesting article, "Boron Treated Electrode Coatings Aid Cast Iron Welding," by Dr. J. A. Neumann, Director of Research, American Agile Corp. Will you please give us the address of this company?

FRANK P. JACOBS,
Chief Engineer
National Radiator Co.,
Johnstown, Pa.

● American Agile Corp. is at 5806 Hough Ave., Cleveland.—Ed.

CENTRIFUGAL CASTING

Sir:

Some of our people here have heard that you have a report on the centrifugal casting process as used by Ford of Canada. Can you tell me in what issue this appeared?

L. J. WISE,
Ass't to Exec. Vice-Pres.
Chicago Malleable Castings Co.,
1225 West 120th St.,
Morgan Park Station,
Chicago

● Dec. 2, 1943, issue, page 54.—Ed.

CONTINUOUS CASTING

Sir:

Kindly send us a reprint of T. W. Lippert's articles in your April 4 and April 11, 1940, issues on the subject of "Continuous Casting."

FRANK R. KEMMER,
Asst. to President
Reynolds Metals Co.,
2827 Hale Ave.,
Louisville 1, Ky.

● See also the comprehensive study of this subject in last week's issue, page 48.—Ed.

ISOTHERMAL QUENCH

Sir:

We would like to obtain one copy of "Isothermal Quench Baths Applied to Commercial Practice" by Harold J. Babcock, as published in THE IRON Age on Feb. 3 and 10.

A. S. JAMESON,
Works Metallurgist
International Harvester Co.,
West Pullman Works,
1015 West 120th St.,
Roseland Station,
Chicago

● Reprints can be obtained from Ajax Electric Co., Inc., Frankford Ave. and Delaware Ave., Philadelphia 23, Pa.—Ed.

"BIG INCH" BREAKS

Sir:

In one of your issues within the last two or three months, we recollect seeing an article which referred to a break in the "Big Inch" pipe line. Could you tell us in which issue this was?

W. E. BANNERMAN,
Asst. General Manager
Page-Hersey Tubes, Ltd.,
100 Church St.,
Toronto

● See page 97, Sept. 9, 1943, issue for the item "'Big Inch' Breaks Are Not Excessive."—Ed.

ARC WELDING DATA

Sir:

About one or two years ago you had a series on "Standard Data for Arc Welding Operations." I understand this was developed by Westinghouse. I am desirous of obtaining three reprints.

W. T. DuRELL,
Time Study Engineer
Ceco Steel Products Corp.,
Cicero, Ill.

● The series, "41 Lessons in Arc Welding," by Westinghouse, appeared in our issues of Feb. 20, Feb. 27, Mar. 6, Mar. 13, Mar. 27, Apr. 3, Apr. 10 and Apr. 17, all in 1941. Reprints are being sent you.—Ed.

ENEMY PATENTS

Sir:

We are very much interested in your weekly publication of enemy patents available from the Alien Property Custodian and as a result obtained from the APC a complete list.

We were rather surprised to find that the description in the APC list does not give anywhere near as much detail as yours.

Would you be kind enough to advise us where you secured the extra information? We presume that you did not go to the trouble and expense of searching the records of this number of patents in the patent office.

C. H. McL. BURNS,
Postwar Planning
Otis-Fensom Elevator Co., Ltd.,
Hamilton, Ont.

● We examined each of the seized patents on file at the Office of Alien Property Custodian, New York City, and prepared a thumb-nail description of each. For the current list see page 102.—Ed.

SIMULTANEOUS PLATING

A method of electroplating three metals simultaneously is mentioned on page 47 of your Feb. 3 issue. It was developed by Westinghouse engineers. We would appreciate receiving information as to which division of Westinghouse was responsible.

H. L. HOVIS,
Works Chemist
Hamilton Watch Co.,
Lancaster, Pa.

● Write to H. B. Blackmon, Public Relations Bureau, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.—Ed.

5 REASONS WHY INDUSTRY LOOKS TO MUEHLHAUSEN FOR LARGE, HOT-COILED SPRINGS!

Controlled atmosphere conveyor type furnace

Complete magnafluxing and magnaglow facilities

Conveyorized enameling and baking speeds output

Specialized facilities enable Muehlhausen to produce springs:

— of any design
— to close tolerances
— in large quantities
— for quick delivery
— of lasting efficiency

One entire plant devoted to hot-coiling—conveyorized for volume manufacture—with control laboratory an active part of production—quenching tanks of swimming pool size—skyscraper-like shot blasters for clean, lustrous finish and added life to springs. A letter will place Muehlhausen engineers at your service—to save you time, cost and effort in obtaining the *right* spring. New, illustrated booklet on hot-coiling springs now available. Muehlhausen Spring Corporation, *Division of Standard Steel Spring Company,* 817 Michigan Avenue, Logansport, Indiana.

To improve product performance, use

MUEHLHAUSEN Designed SPRINGS

Hydraulic Load Tester

Precision hot-coiling springs on automatic equipment

This Industrial Week . . .

- ***Facing Record Needs, Steel Industry Drives to Lift Output***
- ***Clayton Pitches into Intricate Surplus Property Problem***
- ***Two Strikes Cause Loss of at Least 33,000 Tons of Steel***

STRIVING to push production a notch or two above recent high pressure levels, the steel industry is making a good start against March goals which include record requirements that will tax every plate mill in the nation.

Production executives have their fingers crossed concerning unforeseen hurdles such as labor disputes and equipment breakdowns. Fortunately two serious strikes were ended a few days before March began but not before 23,000 tons of steel, 14,000 tons of pig iron, and 14,000 tons of coke had been lost due to the strike at the Carnegie-Illinois Clairton by-product works while at least 10,000 tons of steel were lost in the strike at Great Lakes Steel Corp., Ecorse, Mich. These disputes were the big factors in forcing last week's ingot rate down to 93 per cent. The national rate this week is estimated at 96 per cent.

Meanwhile, the volume of orders reaching steel companies shows little slackening. Plates, sheets, and shapes this week are tighter, while heavy bars, small size lapweld pipe, and other items are in brisk demand. Requirements reflect the fast tempo of the invasion program with its careful planning for every eventuality.

REQUIREMENTS for the Navy's 1945 pontoon program, for which bids on steel are imminent, may be as high as 180,000 tons, including sheets, plates, floor plates, bars, and structurals. Two Army Ordnance packaging programs are under consideration which potentially involve requirements of hot rolled sheets, as previously reported, and black plate, respectively. The fact that new programs are being discussed which would further burden the already over-extended flat rolled production facilities (hot rolled sheets are now into September) has led to speculation that perhaps the War Production Board silently expects that military events will allow cancellations of heavy tonnages now on the books.

Testifying to the awesome proportions of the excess war property disposal problem was the quick action by the administration in appointing William L. Clayton last week as head of the new Surplus War Property Administration (a job which the Baruch report says will affect the well-being of this nation and also that of the civilized world). Clayton is making no hasty statements but has already held many organizational meetings with agency heads and has called a meeting of his policy board this week. The Baruch report will be followed in spirit, he says.

Not only the amount of surplus goods held but market conditions and industrial capacities must be studied. Clayton has indicated that the counsel of Industrial Advisory Committees will be sought.

HOW to get the best brains in the surplus materials field together in one spot will be a puzzler for Clayton. The individuals now are widely dispersed. Army, Navy, Maritime, WPB, and other agencies have been attempting to dispose of surplus materials, each pretty much in its own way, with either no general policy or conflicting policies between the departments and with most agencies having only small specialized staffs. As in the early days of priorities, there has been a confused mass of orders, directives, and red tape, all exerting a drag on the prompt movement of the materials. New problems have been posed by contract cancellations and the accompanying legal angles. Certain officials naturally have been cautious in handling some of the residual material.

The power to declare what is surplus still rests with the procurement agencies and will remain there unless Congress steps in. The War Department particularly has been anxious to retain this power.

On the subject of surplus steel, T. S. Fitch of the WPB Steel Division, in a Baltimore speech recently cited some interesting figures as he urged industries to take the initiative in disposing of surplus material. The government already has sold 4,000,000 tons of excess steel and now has nearly 2,000,000 tons to sell, he said. Should the war end suddenly and immediately, there would be 15,000,000 to 20,000,000 tons of unfabricated steel available.

CONSOLIDATIONS and other shifts which will place the steel industry in a more realistic position in the light of current and postwar actualities gradually are appearing, and more moves can be expected over the near future. Sheffield Steel Corp. is closing its St. Louis works. RFC has ordered work stopped on a DPC-built blast furnace at the Monessen, Pa., plant of Pittsburgh Steel Co. The stack was 95 per cent complete. A move which will concentrate production at a midwestern plant is expected to be revealed soon and it is known that several other producers are contemplating similar steps.

Problems may arise if the heavy volume of steel plate orders wanes later this year. If WPB is not in a position to allocate additional sheet business to wide continuous mills or if reconversion plans have not pro-

gressed to the point where additional sheet business is in sight, there may be sizable idle space on wide strip mills. Total production of all types of sheets last year was almost the same as in 1939, but hot rolled sheets accounted for a much larger percentage of the total, while galvanized, cold rolled and other types were down. The WPB Steel Division is aware of the problems which it may face.

WPB is reported to be preparing to authorize allocations of controlled materials for production of essential war products during the first quarter of 1945. Subcontractors producing essential components also would be aided. WPB is planning to withdraw from the position it has taken in connection with the design of a number of civilian items, thus permitting the use of materials formerly used that are once again in fair supply. Some 65 limitation orders have been redrafted in accordance with this new policy but their actual clearance awaits final approval of the Army.

The controversy over amortization of new freight cars was clarified during the past week. There will be no argument over cars built from now on. The railroads will get WPB certification under which the cost can be amortized over a five-year period. Prior to October, 1943, the railroads obtained certificates from the War Department. With respect to cars ordered between October, 1943, and January, 1944, discussions are still under way and a satisfactory solution of the problem is expected soon. Not many cars were ordered during that period.

WITH the 1944 freight car production goal having been raised from about 40,000 to 60,000 domestic units, the third and fourth quarters of this year should see a record in freight car construction—that is, a record considering the times. It is reported that some car builders are accepting freight car orders on the basis of the ceiling price plus any revisions in prices which OPA may make as a result of the builders' appeal for relief.

In the passenger car field, proposals from the railroads have opened up spirited competition between makers of aluminum, stainless steel, and other materials. This competitive spirit has been keen in other fields recently when prospective business appeared.

Chicago has been placed in the War Manpower Commission's class one labor shortage group. The labor shortage there is estimated officially at 47,000 and the principal employment need is said to be in the radio-radar industry, of which Chicago is the focal point. One aircraft engine plant is not yet fully manned but other similar plants have been thinning out their forces. The steel industry in the area requires common labor but has been weeding out the skilled classifications. Railroads need help badly.

St. Louis Steel Plant Closed

Sheffield Steel Corp. is closing its St. Louis works, because of cutbacks and inability to obtain sufficient orders at the advanced prices granted by OPA last December to warrant further operation.

Raw steel production at the plant ceased last week (about Washington's birthday) and rolling of finished products will be concluded by March 10. The St. Louis works, leased by Sheffield from Scullin Steel Co., includes six stationary basic open hearth furnaces.

High cost of war time operation necessitated Sheffield's making application last fall for price relief. This was granted effective Dec. 20 to allow a charge of 2.55c. per lb., f.o.b. St. Louis on structural shapes, 2.75c. per lb. on merchant bars and 2.60c. per lb. on the tie plates.

The shutdown in no way affects the operations of the company at its main plant at Sheffield Station, Kansas City, Mo.

•

• • • Acting on a WPB recommendation, the RFC has ordered stoppage of work on a DPC-built blast furnace at the Monessen, Pa., plant of the Pittsburgh Steel Co. The WPB recommendation was made because, it said, there is already an adequate supply of pig iron.

The Monessen furnace is 95 per cent complete and if completed would have an annual capacity of 432,000 tons. The cost of the furnace was placed at $6,400,000.

PLURAMELT...YOUNGSTER WITH A FUTURE

TODAY, Pluramelt products are entirely allocated for essential purposes. In fabricated form, they're serving in mess trays aboard ship—in field ranges—in kitchen and hospital equipment for the services—in the manufacture of synthetic rubber, high-octane gas, explosives, etc. The list includes both the single and double stainless-armored types.

In each case, of course, Pluramelt is used instead of *solid* stainless steel. The chief reason, therefore, is the very important matter of conservation. Pluramelt saves 60% to 80% of the vital chromium and nickel that solid stainless would consume for the same job.

But there are other prime considerations. Pluramelt in general fabricates easier than solid stainless steel. And, under any conditions of fabrication and subsequent service, it does not—*cannot*—come apart. Pluramelt is unique—a controlled composite steel with an *intermelted* bond that cannot be separated.

Do you want to know more about this stainless-armored steel that is so sure to bulk large in the peacetime manufacturing of the future? A brand new booklet on the subject of *"Pluramelt Stainless-Armored Steels"* is now ready. Write for your copy.

Take Initiative in Disposing of Excess Steel, Industry Advised

Baltimore

• • • T. S. Fitch, WPB Steel Division Special Assistant in charge of the Surplus Inventory Branch, on Feb. 21 urged that all industry adopt an aggressive policy with respect to redistribution of its own surpluses rather than putting too much dependence on government efforts. Mr. Fitch's proposal was made in a speech before the Baltimore Priorities Discussion Group at the Longfellow Club.

Mr. Fitch emphasized that consumers should take the initiative in disposing of excess steel, particularly small lots. He said: "I think Uncle Sam wants us to do it if we can."

Stating that the government already has sold approximately 4,000,000 tons of excess steel, and now has nearly 2,000,000 tons to sell, Mr. Fitch said that present stocks are made up of small and large lots in controlled material form, and other quantities of partly and fully fabricated steel.

Should the war end suddenly and immediately, there would be 15,000,000 to 20,000,000 tons of unfabricated steel to be sold, he said.

Pointing out that as of Jan. 15, 358,000 tons of idle and excess steel were reported to WPB but that this figure contains a small percentage of government owned excesses, Mr. Fitch said that the Army and Navy and others hold but have not reported substantial tonnages of excess steel. On Oct. 1, Steel Division records showed that there were 1,800,000 tons of surplus steel. "In other words, it would appear that the Services might hold in the neighborhood of 1,500,000 tons at the present time," he remarked.

Analyzing the 15,000,000 to 20,000,000-ton figure which might be surplus on sudden war ending, Mr. Fitch declared that the number of appeals under the CMP inventory regulation show that industry is functioning on a 60-day inventory or less.

He reasoned: "Based on an annual product tonnage of 65,000,000 tons, it would appear that we would have no more than 11,000,000 tons of unfabricated steel. To this would have to be added that steel in production which could not be diverted; it has been estimated that this might be in the neighborhood of 4,000,000 tons. There would also be an additional tonnage made available if the government-owned facilities, such as Navy Yards and Ordnance plants ceased construction immediately after the termination of hostilities. It is our opinion that a top figure of 5,000,000 tons could be ascribed to these facilities. Therefore, we would appear to have a total of something between 15,000,000 and 20,000,000 tons if the war ceased immediately."

◈—— NEWS OF INDUSTRY ——◈

However, the assumption is that the war with Germany will end before the war with Japan and in this case steel excesses will be channeled into essential civilian production.

Mr. Fitch said that there are practical limitations in the future allocating procedure and that it would not be feasible to redistribute less-than-carload lots in this fashion. The movement of smaller quantities could be speeded up by appropriate revision of "L" and "M" orders, now being considered by WPB.

FLAMING LANDMARKS: *The future blazes brighter for Bessemers, according to E. C. Wright of National Tube Co., discussing development of killed Bessemer steel at the AIMME meeting last week. Photo shows converters at McKeesport.*

Regarding small lots of material in primary form, Fitch said such sales cannot be planned centrally, nor is it feasible to establish inventory control.

"We have tried to make it easy to move such small lots by saying in Priorities Regulation 13, that any item of steel worth less than $25 can be sold freely except for the end use restrictions of the L and M orders. It is contemplated that this value will be increased in the near future to $50 per item.

"Perhaps the quickest and most effective method of getting surplus steel in small lots back into the stream of trade is to call in warehouses and/or dealers and solicit a bid on your entire accumulation of small lots."

Discussing for the first time the ultimate disposition of partly fabricated steel, Mr. Fitch indicated no one knows how much of this material will be available after the war, nor what final disposition will be made of it. He expressed the opinion though that the portion not salvagable probably would be scrapped and that the recoverable portion will be sold at advantageous prices.

The Surplus Inventory Branch chief said:

"If to maintain some employment, the government decides to complete any construction which has commenced, then there won't be a particularly severe problem on account of partly fabricated material.

"Instead there will be a problem in the redistribution of idle and excess ships, gun mounts, widgets and Gremlin chasers. It is conceivable that the government will stop such construction shortly after the termination of hostilities, in which case there will be a more serious problem.

"Essentially, this is a problem in salvage and the ratio of recovery will vary with the type of steel. In the case of plates and structural shapes it is conceivable that from 60 to 70 per cent of the weight of the partly fabricated structures could be salvaged.

"In the case of tubular goods, bar and sheet, 40 to 60 per cent might be salvaged. In the case of strip, tin plate, wire and forgings and castings, probably not more than 25 per cent could be salvaged for reuse. * * * *"

Clayton Holds Meeting This Week

Washington

• • • **Surplus War Property** Administrator William L. Clayton on Feb. 25 said that while he thought the Baruch report is a fine one, and that it will be followed in spirit, he could not give any categorical answers to questions until after the new Surplus Property Policy Board has had its first meeting. Mr. Clayton said that the board is to hold its first meeting on March 1 or 2.

One of the very important things Mr. Baruch recommended was that surplus properties be disposed of in the same channels business would employ.

In connection with this, Mr. Clayton said:

"Obviously studies will have to be made not only of the amount of surplus goods the government holds, but of market conditions and the industrial capacity for civilian production above war needs."

Stating that surplus property policy would be divided according to property categories, Mr. Clayton said that the counsel of industry advisory committees will be sought, but it has not been decided that WPB industry advisory committees will be employed.

Mr. Clayton is given absolute au-

Vast Problem of Surplus Materials and Equipment Enters

• • • **The Administration** lost no time in appointing a surplus property administrator, following recommendations made in the Baruch report Feb. 18. William L. Clayton, assistant secretary of commerce, was named head of the new Surplus War Property Administration, which will be known popularly as SWPA. This agency will be under the general supervision of James F. Byrnes, director of the Office of War Mobilization.

The SWPA will have wide powers over the handling and disposition of surplus war property, including the transfer of such property from one governmental agency to another. In general, surplus consumer goods will be assigned to the procurement division of the Treasury; capital and producers' goods to a subsidiary of the RFC; ships and maritime property to Maritime, and food to the food administration. Property to be disposed of outside the U. S. will be assigned the Foreign Economic Administration.

Representatives of 15 departments and agencies will constitute a board which will assist the new SWPA. No government agency can transfer or dispose of surplus property in contravention to its regulations.

Army, Navy, Maritime, WPB and other agencies have been attempting recently to dispose of surplus materials, each pretty much in its own manner. As in the early days of priorities, there has been a confused mass of orders, directives and red tape, all exerting a drag on the prompt movement of the materials.

The first agencies established were Steel Recovery Corp. and similar organizations which sought to put excess but usable materials back into the war production effort. Later the Redistribution Division of WPB took over the task of serving as an intermediary between holders of surplus materials and would-be buyers. An appeal procedure enabled use of some of the surplus materials for non-vital production in consumer goods fields if they don't interfere with the war effort.

New problems are posed by contract cancellations. Obviously, it is considerably easier to move materials which are in excess of war production needs than to dispose of residual material arising from the cancellation of contracts. In addition to numerous legal angles involving settlement of the cancelled contracts, the residual material frequently is in fabricated or semi-fabricated form or gotten up to special specifications.

Officials naturally have been cautious in handling some of the residual material created by contract cancellations through such fears as possible collusion charges or allegations that public money had been wantonly handled. Aiming to achieve a proper degree of prudence so they never could be criticized, the officials have moved most deliberately in some cases.

Haphazard, unregulated sales of surpluses could demoralize the peace-time economy by hampering reconversion, paralyzing new investments, curtailing employment, inflating prices and disrupting normal markets.

At present, Priority Regulation 13 controls most special sales of surplus industrial materials except transfers of surplus aircraft stocks and special sales in the petroleum industry. Under this regulation controlled materials may be sold to fill most authorized controlled material orders and ex-allotment orders. Basic rules for special sales of idle or surplus fabricated components and other products are provided by Priorities Regulation No. 1, although special WPB limitation or conservation orders may set up other restrictions.

War Department—Rules governing the sale and disposal of property owned or acquired by the War Department are generally found in Procurement Regulation 7, originally issued July 6, 1943.

In order to get non-military property back into pro-

Baruch-Hancock Views on

. . . Pointing out that surpluses are beginning to pile up and that still other huge quantities are going to come into the possession of the government, the Baruch report stated that existing machinery clearly is inadequate to handle with dispatch current problems, let alone the much heavier accumulation in the future.

The report recommended immediate creation of an agency capable of dealing with current problems and in so doing gain the experience necessary for handling the greater postwar surpluses. Closest cooperation with WPB was recommended.

Excerpts from the Baruch report on the surplus problem include:

"We recommend, in particular, that the WPB and Surplus Administrator, between them, work out a means by which small quantities of surplus materials can be promptly disposed of so as not to get involved in rehandling or storage problems or tight priority interpretations. Otherwise the clearance of private plants will be hindered and unemployment will result . . .

"There is now in existence an efficient field force of the various agencies . . . This personnel and machinery should be available for the carrying out of the disposal policies that

thority over every agency having surplus property to issue regulations and directions necessary to effectuate the purposes of the order, and no property can be disposed of in a manner not prescribed by him.

The recommendations of overall policy which were contained in the Baruch report and which Mr. Clayton has indicated he will follow are:

1. Sell property as soon as possible without disrupting normal trade.
2. Listen to pressure groups but act in national interest.
3. No sales, no rentals to speculators, none to promoters.
4. Get fair market prices for values with proceeds of sales deposited to the general fund of the Treasury.
5. So far as possible, use same regular channels of trade that private business would in selling.
6. Sell as in a goldfish bowl, with reports always open to public inspection.
7. No government operation of surplus war plants in competition with private industry.
8. No monopoly, equal access to surpluses for all businesses, preference to local ownership but no subsidizing one part of the country against another.
9. Scrap what must be, but no deliberate destruction of useful property.
10. Before selling surplus equipment abroad, assure America's own productive efficiency on which living standards rest.

NO JOB MORE VITAL: *Will Clayton, 64, former southern cotton king, is now Surplus Property Administrator, a post which the Baruch report says will not only affect the well being of the U. S. but of the entire world.*

New Era with Creation of SWPA

ductive use as rapidly as possible, the War Department often makes its availability known concurrently with internal circularization. Lists are usually submitted in five parts:

Part 1, power and motor equipment (power motors, internal combustion engines, turbines, etc.); Part 2, all construction equipment; Part 3, all other items not listed in Parts 1, 2 and 4 which are believed to "have a reasonably foreseeable use in industrial or military purposes or for civilian supply, and which cannot practicably and expeditiously be redistributed without wide circularization"; Part 4, controlled materials; Part 5, all items not included in Parts 1, 2, 3 and 4.

Surplus items listed in Parts 1 and 3 are reported to WPB Regional Redistribution Divisions. Controlled materials listed in Part 4 are reported to the WPB Regional Offices and may be purchased "ex-allotment" without charge against the buyer's CMP allotment. Items in Part 2 are reported to the appropriate Regional Office of the Treasury Procurement Division.

For a period of 20 days after listing with WPB or the Treasury Procurement Division, surplus property is available only to military agencies or other contractors. After the 20-day period, anyone may purchase, although war contractors generally receive first preference. Sales are negotiated by the local officer.

Army Air Forces—The Army Air Forces operate under the general redistribution policy of the War Department discussed above, but maintain separate disposal outlets.

Navy — For the Navy, the assistant chief of procurement and material for industrial readjustment is charged with the establishment, supervision and coordination of all property disposal policies. Lists of surpluses are circularized among the various activities of the Navy Bureau, with a final screening by the Navy Bureau of Supplies and Accounts to determine whether any section of the Navy can make use of the listed commodities. Surpluses are then made available to other government agencies and any items which are still available are placed on sale to the public through competitive bidding by the Navy Office of Procurement and Material. Each of the dozen or more branch offices acts as a clearing house for all surplus materials available in the district under its jurisdiction. Items are grouped into 20 broad categories.

Treasury—The Procurement Division of the Treasury Department disposes of federally-owned surplus stocks made available both by the "old line" government departments and agencies and the newly created government-owned corporations, most of which are controlled by the Reconstruction Finance Corp. The Federal Property Utilization Branch of the Procurement Division has catalogued more than 17,000 different items, ranging from small hand tools to entire operating units. Regional property officers have three methods of disposing of surpluses.

Maritime—Maritime Commission recently created a Surplus Property Section in its Procurement Division. It conducts nation-wide surveys to determine what surplus materials and equipment exist in every yard with which Maritime has a contract. What amounts to a preference rating system of sales is established. First preference is given to shipbuilding contractors.

Important Surplus Disposal Job

are developed. No new enormous field organizations are needed . . .

"The question was asked whether there could possibly be a more important post, affecting not only the well-being of America but also of the civilized world, than that of this Surplus Administrator? The answer was 'No.' It should be added that few government posts are more difficult . . .

"In general, outright sale will be preferable. The disposal agencies, however, should have authority to exchange properties and to lease as well as sell; also to sell on credit and not simply for cash . . .

"We would urge upon the Surplus Administrator a middle course between the two extremes of dumping or freezing—the middle course of wise and carefully-timed disposal. These surpluses, properly utilized, represent tremendous wealth to ourselves and to others . . .

"Timing will be of the essence in the disposal . . . The Surplus Administrator should sell all he can as early as he can, reducing proportionately the quantities of surpluses which will be left for the more difficult postwar period and saving handling and storage charges . . .

"A 'goldfish bowl' policy should be folllowed in all sales."

Whiting's Warning Stirs Industry; Anxious to Maintain Full Output

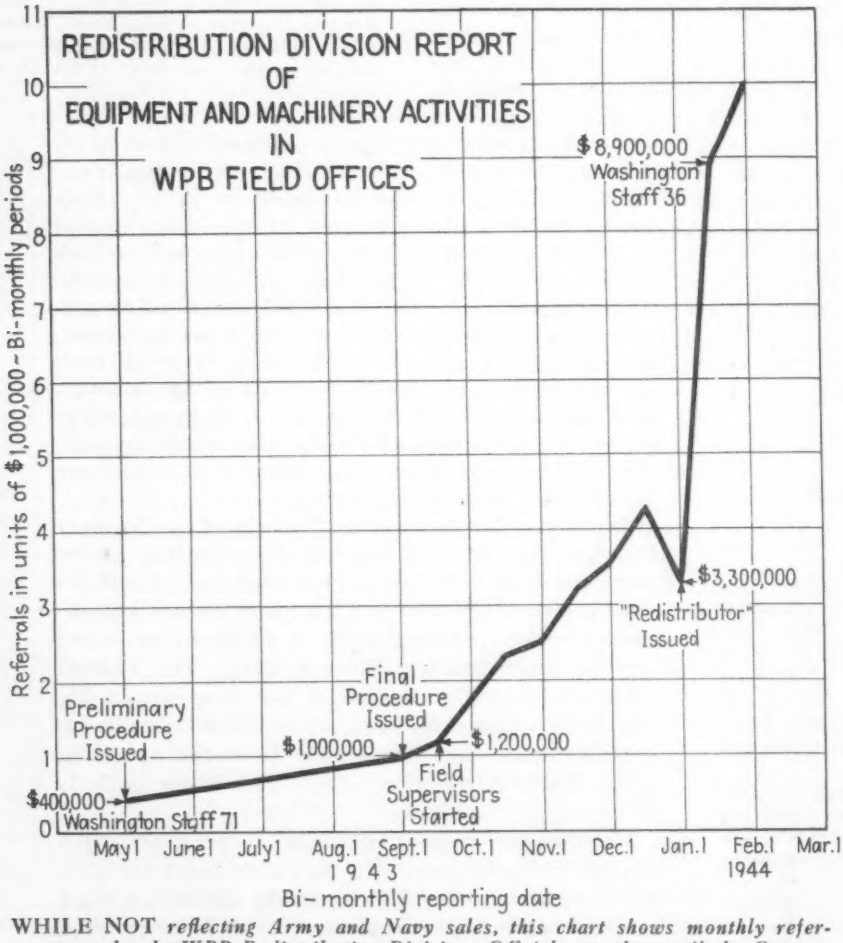
Pittsburgh

• • • **The implied warning** that steel producers should not "rest on their oars or relax their efforts," issued by John T. Whiting, Steel Division director of WPB, recently, was ill-advised, according to opinion in steel circles here. Steel observers recall that several months ago there was a definite trend downward in steel ingot production because of cutbacks in governmental contracts, as well as reduction in Lend-Lease requirements. At that time steel industry officials as well as steel labor leaders warned WPB that unless some expansion was made in essential civilian allotments, a decline in steel output would occur.

The steel industry, it is said, was anxious to maintain full output, and for this reason advocated increased directives by WPB, in order to keep operations at a peak level so that war needs and essential civilian requirements could be taken care of. The union, on the other hand, emphasized the need to keep labor at work and it, too, sought to have WPB keep close tab on any falling off in military or Lend-Lease requirements so that they could be quickly replaced by essential civilian needs.

At no time here, it is said, or in other steel circles, has there been any agitation for return to the production of normal civilian steel products as long as war needs were paramount. There was, however, considerable agitation to increase the allotments to the railroads, to the oil industry, to the farm implement groups, and to steel container manufacturers. Apparently this advice was followed by WPB, since recent trade reports have made it clear, that practically all of these groups which are actively engaged in essential civilian endeavor, have obtained more steel.

Aside from the increase in the flow of material to essential industries, there have also been increases in demand for flat rolled products, which, all taken together, indicate a continuation of present high levels in steel operation. It is pointed out here that the steel industry itself has no control over the production of its products, but makes them at the explicit direction of the WPB. These directives are placed upon the steel companies on a monthly basis; hence, according to opinion here, any "resting on the oars" could not possibly be attributed to the steel industry.



WHILE NOT *reflecting Army and Navy sales, this chart shows monthly references by the WPB Redistribution Division. Officials say that until the Government establishes realistic price policies on this equipment, sales are bound to be slow. It should be noted that after the issuance of the Redistribution Division publication the "Redistributor" sales went up.*

Republic Earns $12,011,057

• • • **Republic Steel Corp.** reported for 1943 a consolidated net income of $12,011,057, which compares with $17,154,578 earned in 1942. Charges against the 1943 net included Federal income and excess profits taxes of $39,300,000 and $4,750,000 provided for contingencies. Sales increased during 1943 to $552,329,000 from $521,110,000 the previous year.

•

Allegheny-Ludlum Earnings

• • • **Allegheny Ludlum Steel Corp.,** for 1943, reported a net profit of $3,865,315 after charges including $600,000 for contingency reserves; $2,000,000 for renegotiation of 1943 war business; and $16,145,000 for Federal taxes. Net income for 1942, after renegotiation, was $4,129,126.

•

Crucible Earns $4,949,696

• • • **Crucible Steel Co. of America** reported net income of $4,949,696 for 1943, as compared with $4,864.781 earned in 1942. Charges against net income were $5,200,000 provided for contingencies and $27,958,855 for taxes on income. No deductions were made for renegotiation of war contracts. Sales during the year aggregated $209,435,789, as compared with a total of $200,704,853 in 1942.

•

Alan Wood Earns $699,230

• • • **Alan Wood Steel Co.** reported a net income of $699,230 for 1943, as against $739,590 earned in 1942. The 1943 net income was reported after deductions for Federal and state taxes, credits for postwar refund, and carryback to 1941 of unused excess profits credit. Also an adjustment of $40,592 was made for over-accrual of Federal income taxes for 1941.

Statistics Bring Out Problems to Be Faced When Volume of Plate Orders Wanes

Pittsburgh

• • • **Under-surface** rumblings, over the possibility of rolling space, but no orders late this year, on the part of those steel companies whose sheet mills are now saturated with plate orders, seem to find some support in latest statistics covering flat rolled production. While total production of all types of sheets in 1943 was almost the same as that in 1939, it was not being produced on the same mills.

Reliable but unofficial indications are that the plate load may be diminished somewhat by July of this year, due, it is said, to the fact that the bulk of the 1944 Maritime requirements will have been produced. Meanwhile, large strip mills which are almost entirely on plates are in no position to accept forward sheet orders to any great extent, due to WPB directives on plates, while on the other hand strip mills and sheet units which are not loaded with plates are being flooded with sheet directives and sheet orders under the CMP.

According to observers here, if the WPB is not in position, when the plate recession sets in, to allocate additional sheet business to the wide continuous mills, or if reconversion plans have not progressed to the point where additional sheet business is in sight, there will be sizable idle space on wide strip mills. There are some sources, however, who predict that a packaging program, requiring the use of sheets, will materialize on an unprecedented scale; but some of the tonnage figures being booted around seem to be far beyond realistic realms.

It is not to be expected that mills predominantly producing sheets, today, would give up any bookings which they have, in case of an easing in the plate load, which would free some wide strip mills; hence, the latter, regardless of some of the name calling in WPB circles, will be definitely "up against it" later this year, unless provision is made or plans are formulated to offset such a situation.

Stated quite simply, a substantial drop in plate requirements would leave wide strip mills high and dry because close to half a million tons of plates a month are being produced on wide strip mills, while other sheet mills are heavily engaged in the production and acceptance of sheet orders. There are some flat rolled officials who believe that forward orders on sheets, for production on wide strip mills later this year, should be allowed to be accepted in order to preclude any substantial void in rolling schedules later.

Steelmakers whose normal pursuits involve sheet production, not only have serious pre-postwar problems, but, according to recent statistics, have a long way to go to regain some of the lost sheet production which has given way to other items because of the war. Total sheet output in 1939 was about 8½ million tons, and in 1943 was about 8,530,000 tons. However, in 1941, before the conversion of the automobile industry and before more drastic controls were placed upon civilian consumption, sheet production for sale reached the unprecedented total of 12,654,000 tons.

It is significant that while production in 1943, on a tonnage basis, was about equal to 1939, total flat rolled output including plates increased 65 per cent from 1939 to 1943. Still more important, while sheets remained static, was an increase of 78 per cent from 1939 to 1943, in the production for sale of all finished steel products. These figures indicate that sheet production has a long way to go to regain its pre-war position, if total steel production after the war, and after an anticipated short recession, should approximate the 1943 level.

Hot rolled sheet output, contrary to the trend in total sheet production, increased from 1939 to 1943, although there was a decrease from 1941 to 1943. On the participation basis, hot rolled sheet production in 1939 was 54.4 per cent of total sheet output, compared to 68 per cent in 1943.

The biggest drop in production among the various types of sheets occured in galvanized, which, in 1939, amounted to 1,395,000 tons, as against 824,000 tons in 1943; or a participation figure of 16.4 per cent of total sheet output and 9.7 per cent respectively. Galvanized sheets may fare better in 1944, owing to the relaxation of some restrictions. Likewise, hot rolled output may be much higher owing to relaxation in controls, as well as increased use of hot rolled sheets for export packages.

Cold rolled sheet output, which in 1939 amounted to 2,022,000 tons, and in 1941 reached 3,025,000 tons, slumped to 1,550,000 tons in 1943; or, in other words, from about 24 per cent of total sheet output to 18.2 per cent. This again was to be expected, in view of the conversion of the automobile industry.

The unprecedented records made and being made on wide strip mills and mechanized sheet mills as well, certainly indicate that flat rolled capacity on a practical basis is, and will be, far greater than that recorded for the same units before the war. A study of the figures shown in the table, when compared with the complete flat rolled compilations, covered in this magazine Feb. 24, page 106, clearly indicate the tremendous problem to be faced on the sheet picture when the volume of plate orders begins to drop off sharply, as is expected later this year. It represents, probably, one of the biggest potential headaches for the WPB later on—just as big, or bigger, than when sheet mills were converted to plate production.

Non-Steel Producers Inclusion In Steel Wage Case Adds Confusion

Washington

• • • **The muddled "steel"** wage case, with its already ramifying aspects and conflicts, became more confused at a WLB "procedure" hearing on Feb. 23. With a scant attendance of members, the board summoned before it what a press statement had previously said would be 74 steel companies, on the question of extending contracts with the CIO-USW.

Actually many of the companies represented at the hearing, some 40 in number, are not even remotely connected with the steel business. There were slag producers, paving brick manufacturers, enameling concerns, and a miscellany of other lines whose representatives were befuddled over the whole thing. In vain they tried to find out why they were dragged into the proceeding.

Others sent answers to the board, and like those present, protested against their being drawn into the steel case, and objected that their wage scale is generally under the steel wage level. Some said that they could not possibly pay the steel wage scale. All, however, have had or now have USW contracts. Some have expired. Others have been extended, an indication of how widespread USW organization has been in other fields as well as in steel.

The explanation of the inclusion of non-steel companies in the case, however, was cleared up somewhat by WLB vice chairman George W. Taylor, a public member who presided. Dr. Taylor told the attorney for one company that the case covered all companies that have USW contracts. Broadening of the proceeding to this pattern aroused renewed charges that the CIO is seeking union-wide rather than merely industry-wide contracts and its AFL rival, already in a row with USW in the steel case, has become increasingly anxious over the penetration into its field of CIO organizations.

The board itself originally spoke of the case as involving only two groups, the "basic" steel companies and the "non-basic" steel companies. Whatever the board's definition of the terms "basic" steel and "non-basic" steel, its terms did confine the case to steelmakers and steel users. It also said that approximately 500 steel companies were included in the proceedings.

Non-steel companies, however, which have been dealing with USW find themselves mixed up in the case and were given 10 days in which to file answers to show cause why an interim order should not be issued extending USW contracts calling for retroactive pay in the event the board orders a readjustment of wages as set forth in the board's Carnegie-Illinois, et al order of Dec. 23, 1943. The move, of course, is to break the Little Steel formula wide open.

The companies represented at the hearing tried to get an interpretation of the order to learn the distinction between it and the national stabilization policy. Dr. Taylor told them that that was a question for the board to handle. Eugene Catton, USW attorney, offered the vague explanation that the only motive of the order was to "stabilize the relationship with industry till the issue could be resolved by the board."

AFL has clashed with USW in asking that the President modify the Little Steel formula while USW is asking that it be set aside. In view of USW's broadening the case to go beyond the formula, AFL is, so far without success, asking that it be represented on the six-man steel panel which will hear the steel case, still in its "procedural" stage and moving at a snail-like pace.

Meanwhile WLB has announced that the panel will hold its first meeting with USW and some 100 "basic" steel companies on March 8 to consider the issues to be heard and the procedure to be followed. Immediately after the hearing the panel will report to the board for further instructions. The panel will than hear the parties on the merits of the case. The board said that this hearing will begin March 14.

Manpower Plan Takes Effect

Pittsburgh

• • • **The Pittsburgh Manpower Budget Plan** went into effect on March 1. Essential industries that come under classification No. 2 have had Feb. 1, 1943, set as their employment ceiling. The number of male employees in service at that time is the base from which allowable hirings are made.

Essential industries fall into group No. 2, until such time as the employer can qualify for group No. 1. This group includes companies with direct Army, Navy, or Maritime contracts. Employers in group No. 1 may hire for expansion and replacement, but individual ceilings are to be set after consultation with the Manpower Commission.

The essential group, No. 2, may hire on the basis of four per cent a month of its Feb. 1 male payroll, a figure that represents about the average employment turnover in this area. In case the company feels it needs more than a four per cent hiring rate in any given month because of unduly large armed force inductions, it may seek adjustments from WMC.

The plan also includes assignment of priorities to companies in groups

200 TON MOLD: *This corrugated one-piece ingot mold, weighing 400,000 lb., was cast at the Bethlehem plant of Bethlehem Steel Co. It is 111 x 199 x 165 in. (deep) on the outside. It was poured on Jan. 15 from two 150 ton and two 15 ton ladles, using about 500,000 lb. of metal.*

one and two when referrals are made by the United States Employment Service to companies needing additional workmen. Companies in groups one and two may also hire privately, as long as they abide by the WMC regulations.

Inauguration of the Pittsburgh Manpower Budget Plan was discussed in THE IRON AGE, *Feb. 17, page 109.*

A ceiling has been set at Feb. 1 for the non-essential group, No. 3. However, no additional male employees other than part-time young boys or veterans of this war may be hired now except through specific permission of the USES. It is through the control over this group that WMC expects more manpower to be available to groups one and two.

One of the chief features of this plan will be the requirement of every employer to report, semi-monthly, the names and addresses of all men hired within that period. The possession of such a list will enable the USES to keep a check on possible violations in transfer rules and regulations either on the part of employee or employer.

Canadian Labor Code Provides Penalties for Labor and Management

Ottawa

• • • **The Canadian government** has enacted a national code, effective Feb. 17, in wartime labor relations affecting 2,500,000 of the estimated 3,500,000 industrial employees in the Dominion. The code, under the authority of the Wartime Measures Act, has been in the making since last summer's National War Labor Board inquiry into labor relations. Its regulations, providing for compulsory collective bargaining and outlining conditions of fair labor practices, apply only to war industries and those occupations which came under the Industrial Disputes Investigation Act, which they now supplant.

There is nothing in the code which prohibits the Provinces, through legislation, to bring all non-war industries, now exclusively under Provincial jurisdiction, within the application of the code in interest of the uniformity which was sought originally by the Dominion department. Administration of the code, as it would apply to non-war industries, would have to be by agreement, between the Dominion-Provincial governments, with possibly a joint administration.

While the code is effective immediately, the composition of the Wartime Labor Relations Board, the administration board, has not yet been announced. The board will consist of a chairman, a vice-chairman and not more than eight other members. Also, provided for is employer and employee representation on an equitable basis. Strikes or lockouts still are possible under certain conditions, but only after collective bargaining efforts have failed, and a conciliation board report has been before the Labor Minister for 14 days without completion of an employer-employee agreement. Uniform labor practices applying to employers prohibit attempts to dominate or interfere with trade unions and employees' organizations or to contribute financial support to them.

Neither side is obliged to accept the finding of a conciliation board and there compulsion ceases. Full provision is made for the renegotiation of agreements, and strikes are prohibited in a termination of an agreement. In other words, there must be a similar process as in the event of a new agreement. Terms are given that are designed to eliminate jurisdictional disputes and the raiding of one union by the members of a rival union. Behind them stands a list of penalties, applicable to both sides in a labor dispute, in the event of the regulations being broken.

The regulations are designed to place on both parties a joint responsibility for a settlement by their own action.

The new Wartime Labor Relations Board will be responsible for matters of policy and such regulations as are necessary to insure uniformity in application of the code. Unions are prohibited from coercion or intimidation of workers to force them to join an organization. Activities in plants during working hours in an effort to enlist union membership are banned and no support or encouragement may be given to slow-downs or other interference with production. All collective agreements must include a grievance procedure for settlement of disputes without stoppage of work. If no procedure is provided in existing agreements, the board may establish one. In cases where there is no agreement and a dispute arises, a 60-day delay is provided to enable the employees to elect bargaining representatives.

The main provisions of the labor code are:

1—Establishment of a Wartime Labor Relations Board comprising a chairman, vice-chairman and not more than eight members.

2—Certification by the board of bargaining agencies representing the majority of employees in affected industries.

3—Compulsory negotiation between employers and certified bargaining agencies.

4—Conciliation procedure if negotiations for an agreement fail.

5—Prohibition of strikes during the selection of a bargaining agency, negotiation of an agreement, conciliation proceedings if necessary, and the life of the agreement after it is adopted.

6—A definition of unfair practices by employers, employees and unions.

Penalty clauses include:

1—An employer who causes an illegal lockout: A fine of not more than $500 for each day of the lockout.

2—An employee who strikes illegally: A fine of not more than $20 for each day on strike.

3—A union or other organization authorizing an illegal strike: A fine of not more than $200 for each day of strike.

4—Persons or organizations contravening any sections of the code for which specific penalties are not provided: A fine of not more than $100, against an individual or a fine of not more than $200 against a corporation or organization.

5—Persons offering bribes to those charged with administration of the code or officials who accept a bribe: A fine of not less than $500 and not more than $5000, or imprisonment for not less than six months and not more than five years, or both fine and imprisonment.

CITATION WINNER: *Walter C. Wolfe, cupola tender at the manpower-short Chicago Hardware Foundry Co., Elkhart, Ind., was cited by the Gray Iron Founders' Society for staying on the job despite a fractured leg. The citation was accompanied by a $100 war bond.*

23,000 Tons of Steel Lost Through Outlaw Strike in Pittsburgh District

Pittsburgh

• • • **An outlaw strike** by less than 400 coke oven workers at the Carnegie-Illinois Clairton by-product plant reduced the flow of open hearth fuel to Corporation plants to such an extent at midnight, Feb. 25, that more than 90 open hearths were shut down, and in excess of 20 blast furnaces were forced to have their wind reduced. The strike, caused by alleged "promotional sequence" inequalities, ended Sunday, Feb. 27, but full operations at the affected plants was not resumed until Feb. 28. About 23,000 tons of urgently needed war steel was lost due to the wildcat strike. The pig iron loss was 14,000 tons and the coke loss was 14,000 tons.

The walkout in the by-product plant shut off the flow of gas necessary for open hearth furnace operations, and further affected some processing of finished material due to lack of fuel for heating furnaces. With the open hearths down, the management was forced to cut the wind on the stacks. A seamless mill at the National Tube works at McKeesport was also shut down for a day, and resumption of Carnegie's Irvin Works 80-in. hot mill, now working on plates, was delayed.

Armor plate production, for Navy landing barges came to a standstill on Feb. 25 at Great Lakes Steel Corp., Ecorse, Mich., when 6000 workers struck. Thomas Shane, district 29 director of the USWA-CIO claimed the major cause was that for "the past 18 months the men have been working in short-handed crews" and had not been compensated for the extra work, but the discharge of a union employee precipitated the strike. The company maintained that violation of management rules and procedures was involved in the discharge.

Union's Cost of Living Data Flayed

Washington

• • • **Exhaustive** in detail, A. F. Hinrichs, Acting Commissioner of Labor Statistics, last Saturday submitted a report of the Bureau of Labor Statistics to WLB Chairman William H. Davis in which the commissioner stoutly supports the Bureau's cost of living index which had been attacked by George Meany and R. J. Thomas, labor members of the President's Committee on the Cost of Living.

Clearly designed as a pattern from which to build CIO-USW's case for a 17c an hour increase in steel wages, the Meany-Thomas report was made public Jan. 25 by CIO President Philip Murray before the WLB had a chance to study it. The labor report contended that the cost of living had risen 43.5 per cent since January, 1941, the basis on which the Little Steel formula was fixed. The Bureau of Labor Statistics said the cost of living had risen 23.5 per cent since that period.

With a wealth of facts and textual discussion to back up the BLS report, Mr. Hinrichs said that the claim of the Meany-Thomas report that the cost of living has risen 43.5 per cent is not supported by their data.

"Rather," said Mr. Hinrichs, "there is conclusive evidence that they are absolutely wrong in asserting that the rise in the cost of living is nearly twice as great as the BLS shows it to be (23.4).

"The report contains many errors of fact, and makes use of unrepresentative data to support its general conclusions. It does not meet the high technical standards which usually have characterized trade union research."

Legislative Proposals Outlined In Appendix to Baruch Report

• • • **An appendix** to the Baruch-Hancock report (now available in printed form from the Superintendent of Documents for 20c.) briefly outlines the legislative policy it proposes and is taken to be an answer to criticism that the report contemplated that the problem of postwar adjustment be done only by executive orders.

"Congress should lay down whatever policies it feels wise and desirable to guide the existing agencies in their handling of demobilization," it is pointed out.

The report proposes that the Work Director work with Congress on a combined program of legislation and operations for the entire human side of demobilization; legislation for the selling of terminated war contracts; the Surplus Administrator to report to Congress as soon as possible on legislation needed for surplus government property; extension of price control law, the priorities and allocations powers on which the functioning of WPB rests, and the requisitioning power of the President; extension of Smaller War Plant Corp.'s lending authority to permit changeover assistance; liberalization of Federal Reserve's authority to make industrial loans; postwar tax on the shelf; Congress consider funds for engineering public works shelf.

The appendix lists the more important aspects of the roles of WPB and the armed services as follows:

Armed Services: To decide what weapons and war supplies should be cut as the war changes, informing WPB as soon as such cuts are decided; to work with the WPB and other civilian agencies, including WMC on the choices of which contracts are to be cancelled; to negotiate settlements of what the government owes on terminated war contracts after cancellation; to assist the Surplus Property Administrator in promptly clearing government property from war plants; to work with him and the WPB on redistributing surplus property to stimulate war production; to be prepared to shift contracts to make use of plants and manpower freed by cancellations; to work with WPB in the preparation of a "X-Day" reconversion plan; to work with the "Work Director" on the demobilization of the armed forces when that becomes possible.

WPB: To keep the program of production for war and civilians in constant balance; to lay down the policies to guide the choices for cancelling contracts of war goods no longer needed; to work with the Armed Services and other procurement agencies and with WMC and other civilian agencies in making the actual choices of producers to be cancelled and those to be left in war production; to guide the shifting of contracts to make use of facilities or manpower freed from war production; to decide what civilian production and employment is to be resumed as war needs slacken; to work with the Surplus Administrator and Armed Services on the disposal of surplus government property so as to stimulate both war production and resumption of civilian employment; to keep all war controls under constant review so that they can be promptly modified; to review worthwhile local projects deferred during the war that may be cleared as war needs slacken.

•

Report Procedure Mapped

Washington

• • • **WPB is** developing a procedure for the receipt and distribution of contract termination reports from the procurement agencies pursuant to recommendations contained in the Baruch report.

The WPB Statistics Division through form GA-1330 will seek information on contract cutbacks where the cut is more than 25 per cent and for more than $50,000. Procurement agencies will tell WPB the name and address of the contractor, end products terminated, monthly rate of production before and after termination, plans for future use of part or all of plant capacity released and the estimated date when production plans will begin and approximate percentage of released capacity that will be utilized.

Other information such as available equipment and labor will be secured by the WPB regional staffs.

Armco Plans River Terminal

Cincinnati

• • • **Plans for the** construction of a large river harbor terminal at Cincinnati for the American Rolling Mill Co. as a rush war project were revealed last week. The terminal would clear the entire coal requirements of Armco's plant at Middletown, and receive return loads of steel for Ohio River shipment. It is to be one of the most modern terminals in the vicinity and will be rushed to completion as quickly as possible to help facilitate steel output at Middletown, and delivery, by water, to war plants where feasible. According to plans revealed at the City Council meeting at Cincinnati, where the petition for legislation to permit construction was presented, the cost of the improvement was estimated at about $500,000. In addition, it was reported that Armco is purchasing about 27 to 30 acres of ground on which to make the improvement, should the legislation be passed.

100,000th Centrifugally Cast Gun Tube Made at Watertown Arsenal

Boston

• • • **The casting of the** 100,000th gun tube by the centrifugal casting process at the Watertown Arsenal was announced on Feb. 20. Actually, however, many more than this have been cast centrifugally at the Arsenal.

The process first was employed in 1938, with one casting machine operating eight hours per day, five days a week, with a crew of 15. By 1942, 14 machines were operating 24 hours a day, seven days a week requiring a crew of 288. In 1943, the crew had to be increased to 550.

During the two years immediately preceding the entry of the United States into the war, practically the entire modern gun tube program for the Army was carried on by this Arsenal alone. During 1940, some 1600 tubes were produced centrifugally by Watertown, the capacity of the equipment at that time. In the year and a half following Pearl Harbor, production jumped 26 fold. During 1942, until civilian industry had begun to produce its full share of gun tubes, the Arsenal carried a substantial portion of the 90, 105, and 40 mm. tube-making burden. By 1942 it had produced more than 40,000 tubes.

The centrifugal casting foundry at Watertown is more or less conventional, with casting machines at both ends. Directly behind the casting machines and about 15 ft. above them are the melting platform and control equipment. Electric melting furnaces are picked up and carried to the casting machines. After the cast, the tube number is stamped on it and it is carried to cinder pits for cooling.

The late Brig. Gen. Tracy C. Dickson is generally credited with being the father of centrifugally cast gun tubes. He was in command at Watertown Arsenal from 1918 to 1932.

Industry's Expansion Funds Tie U. S.

New York

• • • **The steel industry** has matched the government's funds dollar for dollar in financing the two billion dollars emergency wartime steel expansion program started in 1940, according to the American Iron and Steel Institute. From 1940 through 1944, steel companies have spent or will spend $1,151,000,000 in developing new ore mines, building new blast and steel furnaces, and installing other items of new equipment. Over the same period, government funds pro-provided for the same purpose total $1,063,000,000.

As a result of these expenditures, new ore mines with an expected annual capacity of 15,000,000 tons of ore have been developed or are nearing completion. Since January, 1940, nearly 14,000,000 tons of new blast furnace capacity, and over 12,000,000 tons of new steelmaking capacity have been built.

In 1941 the industry increased its new equipment expenditures 70 per cent over the previous year to a total of $295,000,000. The government-financed part of the program began late in 1941, reached a peak in 1943, and will taper off sharply in 1944.

In 1944, the steel industry will spend $181,000,000 of its own funds for new equipment and construction, about 25 per cent less than $239,000,000 spent in 1943 for these purposes. The $131,000,000 of government funds to be spent in 1944 for new equipment is 75 per cent below the total of $516,000,000 spent by the government during the year 1943.

"World's Largest Known Ore Mine" Opened in Brazil

• • • **Installation of power** and industrial equipment this year at Caue peak, Brazil, center of the world's largest iron ore deposit, will open up an important new source of ore for United Nations war plants, the International General Electric Co., has announced. Described as "the greatest known hard-ore mass, and easy to equip, develop, and mine," the area contains an estimated 15 billion tons of ore suitable for high-grade steel. Beginning this year and continuing for three years, annual production of one and a half million tons of ore will be divided between the United States and Great Britain.

The peak is located in the province of Minas Geraes about 4500 ft. above sea level. There is no overburden of earth, and open pit mining, with drilling and blasting, will begin near the top. Two large electric shovels, powered by GE drives, will load the ore into trucks which will carry it three-quarters of a mile to the processing plant.

The railroad from Itabira, the location of the mine, to the Atlantic ocean port of Victoria, 350 miles away, is being rerailed and rehabilitated.

WOMEN BUILD BOMBERS: *Playing an increasingly greater role in aircraft construction, women are becoming more essential daily to aircraft quotas. These women are a working team in the fuselage assembly department of Bell Aircraft Corp.'s Marietta, Ga., plant where newer types bombers are built.*

Gray Iron Casting Price Changes Effected to Stabilize Price Structure

• • • **Six changes in the** provisions governing maximum prices for gray iron castings were announced by OPA. The net effect of the changes, OPA said, should be to provide a more stable price structure in the gray iron castings field.

The changes are as follows:

1—Sellers of gray iron castings using the "base period" method of computing maximum prices, beginning March 1, 1944, are authorized to add overtime labor costs in calculating ceilings. This may result in an increase of two to three per cent in the level of maximum prices for gray iron castings. It will, however, tend to stabilize prices, for previously producers were authorized to add overtime labor costs in computing maximum prices under the "formula" and "pre-base" period pricing methods.

2—In computing ceiling prices for "short orders" (orders where the shipping weight of the casting multiplied by the quantity ordered does not exceed 200 lbs.), the maximum price must be determined by multiplying the shipping weight of the casting by twice the seller's average price per lb. for gray iron castings in 1942 and by adding a starting charge of $8 for non-cored or $12 for cored castings. This simplified pricing method was authorized by OPA after consultation with representatives of the industry. Previously "short orders" had to be priced in the same manner as any other orders for castings.

3—Sellers of castings under the "formula" method hereafter are permitted to recompute ceiling prices only once on any casting sold under that pricing method. Limitation to one recomputation is designed to stabilize ceiling prices, removing price uncertainties for both buyers and sellers.

4—In a revision of pricing provisions, any seller of gray iron castings who delivered a casting during the base pricing period Aug. 1, 1941, to Feb. 1, 1942, now must use the "base period" method of establishing his ceiling price for that casting, no matter whether the contract for the delivery of the casting was made before or after Aug. 1, 1941. Previously it was possible for the seller to use the "formula" method of pricing if the contract was entered into before Aug. 1, 1941.

5—Sellers of castings under the "pre-base" pricing method, once they have chosen to use this method to price castings 30 days after the effective date of the amendment, may not shift over to the "formula" method of pricing. This action is also being taken to stabilize ceiling prices for both sellers and buyers.

6—The scope of the "base period" method of computing maximum prices now is narrowed, with the result that more castings will be priced by the "formula" method. This is accomplished by providing that in order that a casting may be priced by the "base period" method, the *identical* casting must have been sold or offered for sale by the seller in the base period. If *substantially the same* casting was sold or offered for sale in the base period, a maximum price is thereby established only if it was sold or offered for sale to the purchaser to whom the casting is presently being priced.

The three methods for determining maximum prices for gray iron castings are: The first, or "base period" method, established maximum prices at the highest prices at which the seller sold the casting between Aug. 1, 1941, and Feb. 1, 1942.

The second, or "formula" method, establishes maximum prices for castings not sold or offered for sale during the base period, by use of the seller's pricing formula (including costs, overhead rates) which he employed on Feb. 1, 1942.

The third method for determining maximum prices is the "pre-base period" method, and the seller has the option of using this method in lieu of the formula method. Under the "pre-base period" method the seller uses as his maximum price for a casting not sold or offered for sale during the base period, the price at which he last delivered the casting prior to Aug. 1, 1941.

Senate Committee Delves Cost-Plus-Fixed-Fee Contracts

Washington

• • • **Exploratory hearings** on a Joint Resolution to prohibit further use of cost-plus-fixed-fee contracts will be opened this week, Sen. James E. Murray, Mont., chairman of the War Contracts Subcommittee of the Senate Military Affairs Committee, announced.

The committee is now investigating complaints that an unbelievable waste of manpower and money has resulted under the cost-plus system, Sen. Murray said.

The measure to be considered, Senate Joint Resolution 80, introduced by Sen. Homer Ferguson, Mich., lays down two basic policies:

1—No new cost-plus-fixed-fee war contracts may be awarded except where the head of the contracting agency personally certifies it is necessary to do so "because of lack of precedents or experience upon which to base fixed prices."

2—All outstanding cost-plus-fixed-fee contracts are to be shifted as rapidly as possible to a fixed-price basis.

A third provision requiring the mandatory use of "incentive fees" in all cost-plus-fixed-fee contracts awarded or continued in the future, will also be considered. Some of the war agencies claim to have made headway in developing cost-plus-fixed-fee contracts with incentives for lower costs, Sen. Murray said, by increasing the contractor's fee when his costs go down and his production rate goes up.

The schedule of witnesses for the preliminary hearings is as follows:

March 2—Donald M. Nelson, War Production Board; Paul V. McNutt, War Manpower Commission.

March 3—Various persons who have complained to the committee about waste under cost-plus-fixed-fee contracts.

March 6—Lindsay Warren, comptroller general; Admiral Emory S. Land, Maritime Commission.

March 7—Robert P. Patterson, under-secretary of War; James V. Forrestal, under-secretary of the Navy.

CMP Developments

• Dir. 2 to Reg. 9A rules that repairmen may use only up to $25 worth of material purchased under procedures contained in the regulation for installing any unit of cooking, plumbing, heating or used air-conditioning or refrigeration equipment. (Release No. WPB-5068)

•

• Reg. 5, as amended, makes it possible for persons desiring to purchase aluminum for MRO purposes to obtain it in the same manner that steel and copper in controlled materials forms and shapes are obtained. (Release No. WPB-5064)

•

• Dir. 47 to Reg. 1 permits a producer of steel in controlled material forms and shapes to accept orders for delivery of his products in excess of amounts that he is ordinarily permitted to accept under WPB regulations, if he is able to fill the orders from stocks that are available in his mill. (Release No. WPB-5039)

•

• Dir. 26 to Reg. 1 modifies rules governing returns of excess or unused allotments of controlled materials to bring them into conformity with WPB's decentralized operations. (Release No. WPB-5006)

Steel Order Acceptances

Washington

• • • **A producer of** steel in controlled material forms and shapes may accept orders for delivery of his products in excess of amounts that he is ordinarily permitted to accept under WPB regulations if he is able to fill the orders from stocks that are available in his mill, the WPB Controlled Materials Plan division announced on Feb. 24.

CMP regulations ordinarily prohibit producers of steel in controlled materials forms and shapes from accepting orders for their products in excess of 110 per cent of production directives that have been served on them by WPB or in excess of 105 per cent of anticipated monthly production in the event no production directives have been served.

The ruling, contained in direction 47 to CMP Regulation 1, indicates that orders which a producer is permitted to accept under the terms of CMP regulations may be accepted in excess of these limits if, but only if, the producer is able to fill them from items that he has in stock.

MRO Order Changed to Permit More Extensive Aluminum Use

Washington

• • • **Rules governing** maintenance, repair, and operating supplies (MRO) under CMP have been modified to make it possible for persons desiring to purchase aluminum for MRO purposes to obtain it in the same manner that steel and copper in controlled materials forms and shapes are obtained, the WPB announced on Feb. 26.

In addition, the limit of 100 lb. of aluminum for MRO purposes that formerly applied has been eliminated. Under the new rules the only limit on amounts of aluminum that may be bought by a person eligible to use the MRO symbol for the purchase of controlled materials is the purchaser's MRO quota.

The procedure that formerly applied required that a special form of certification had to be used by persons purchasing aluminum under the MRO regulation. This is no longer necessary. Under the new procedure, persons purchasing aluminum for MRO purposes need no longer certify that the use of other materials would be impracticable and that the total amounts of aluminum on order do not exceed 100 lb. for the calendar quarter in which delivery of the order is requested.

Elimination of the limit on purchases of aluminum for MRO purposes has made possible the elimination of an appeals procedure under which it was possible for users to make special application for permission to purchase in excess of 100 lb. of the metal.

The amended order also provides that if an appeal for an increased MRO quota has been granted by WPB, the increased quota may be used for operations during quarters subsequennt to the one which it was originally granted. This rule holds unless a substantial part of the increased quota was granted to take care of an abnormal situation.

The amended regulation points out that persons who use its provisions to obtain MRO materials must compute their MRO quotas and must maintain a record of them. In addition, it points out that records of expenditures against the quota must also be maintained. As a result, Direction 13 to CMP Regulation 5, which formerly required that quotas be computed, as now been revoked in view of the fact that the provisions are now spelled out in CMP Regulation 5 itself.

Price Briefs

• Amdt. 48 to RSR 1 exempts sales of brucite to producers of magnesium from price control. (Release No. OPA-T-1766)

•

• Amdt. 2 to MPR 1 allows sales of second-hand machine tools for the government to be certified instead of guaranteed.

•

• Amdt. 109 to MPR 136 permits substitution of certificates of operation in creditor sales by government.

•

• Amdt. 6 to RPS 69 establishes a new basing point for sales of primary lead at Bayfield, Wis. The maximum price for lead delivered at Bayfield in carload lots is 6.50c. per lb. (Release No. OPA-3938)

•

• Amdt. 108 to MPR 136 provides that the extra costs of silver-bearing solder and other emergency measures involved in the production of servicing machinery may be passed on to the consumer. (Release No. OPA-3935)

•

• Amdt. 8 to RPS 12 places a ceiling price of 5⅝c. per lb. f.o.b. point of shipment on briquetted cartridge brass turnings. (Release No. OPA-T-1751)

•

• Amdt. 89 to MPR 120 grants permission to producers in Bituminous Coal Producing District No. 8 to sell bituminous coal to two railroads for use as locomotive fuel at maximum prices established for commercial fuel. (Release No. NB-2154)

•

• Amdt. 95 to RSR 14 permits the War Department to reach agreements with warehousemen on storage charges where the warehouseman cannot set his ceilings by reference to identical services performed in March, 1942. (Release No. OPA-T-1765)

•

• Amdt. 87 to MPR 120 provides a means whereby distributors of a certain limited amount of bituminous coal normally marketed through distributors, may, under certain specified circumstances, obtain on their sales a price above that charged by the mine. (Release No. OPA-T-1740)

•

• Amdt. 27 to MPR 306 extends maximum prices established for the 1943 fruit and vegetable pack to fruits and vegetables packed up to the time that a 1944 pricing regulation is issued. (Release No. OPA-3969)

•

• Amdt. 7 to MPR 244 makes six changes in the provisions governing maximum prices for gray iron castings. (Release No. OPA-3956)

Deliveries Restricted on New And Used Container Machinery

Washington

• • • **All deliveries of** new and used container machinery, including that used for packaging and labeling, can closing, can making, glass jar and bottle making, and cleaning or reconditioning, will be restricted after March 1, WPB announced. In addition to requiring an AA-5 priority or better for delivery of this type of equipment, monthly operational reports must now be filed by manufacturers to assist the WPB in calculating trends on the demand for this type of equipment and the ability of producers to supply such demands without interfering with their war orders.

Formerly some types of container machinery came under the provisions of L-83, but because of the complex nature of this business the WPB decided to issue this separate order, L-332, to cover operations of their branch of industry.

Meyers, Creighton Latest To Leave Steel Division

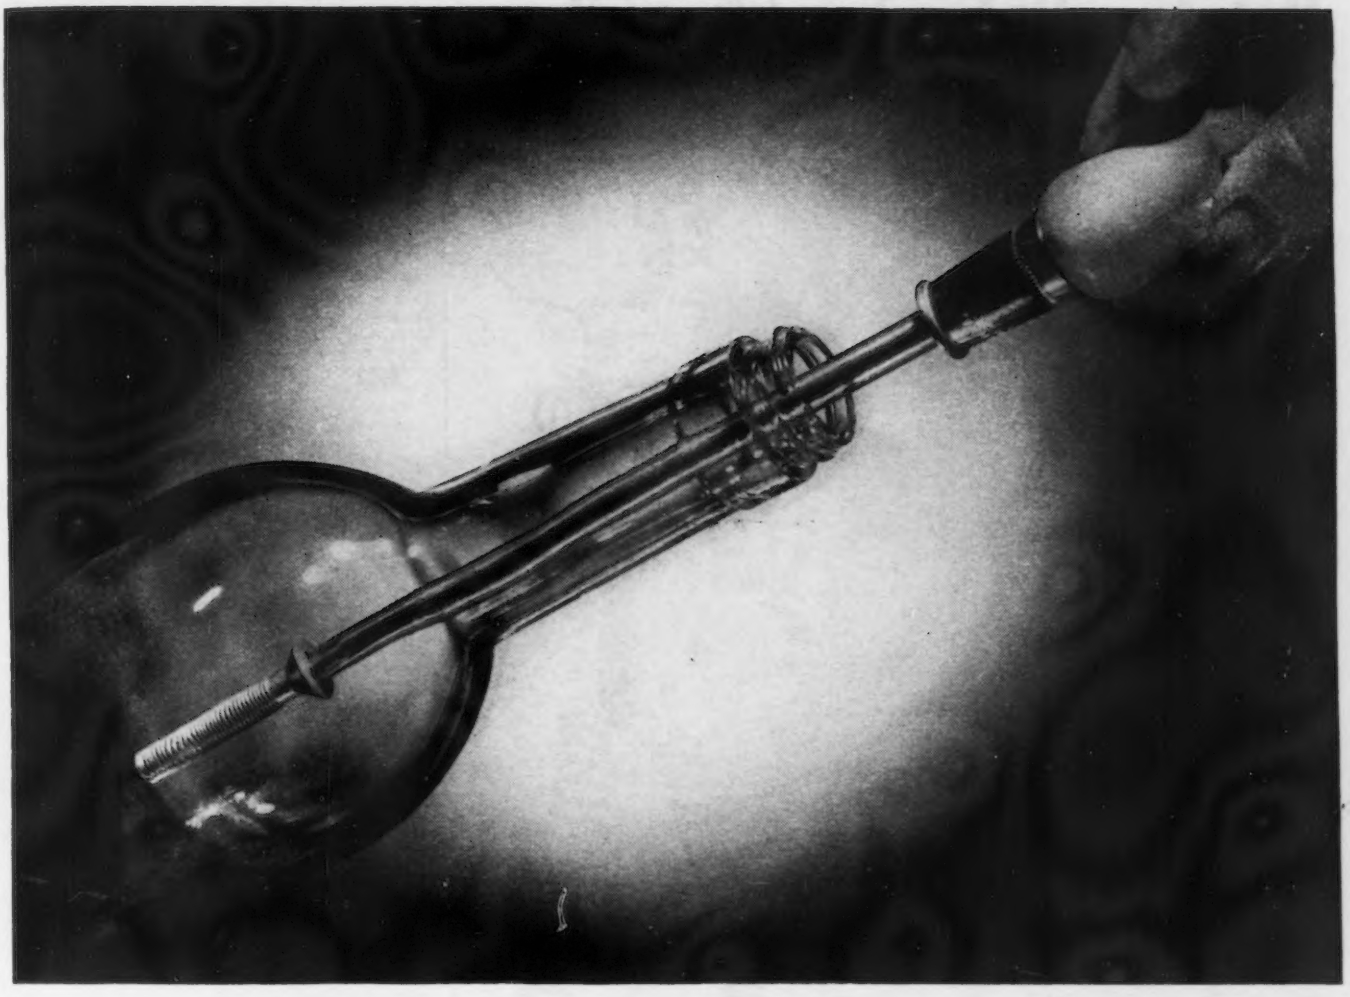
Washington

• • • **C. W. Meyers,** assistant director of the WPB Steel Division, has resigned, effective March 1. Mr. Meyers, who was manager of the Central Alloy District of the Republic Steel Corp. before coming to Washington to assume charge of the Steel Division's Raw Material and Facility Branch, will go back to Republic.

Louis E. Creighton, vice-president of the Rotary Electric Steel Co., who has been chief of the Steel Division's Alloy Steel Branch for the past year, resigned from WPB effective Feb. 29, to resume his former position.

COMING EVENTS

March 14, 15—National Association of Waste Materials, Inc., New York.
March 27, 28—American Society of Tool Engineers, Philadelphia.
March 30, 31—American Gas Association War Conference, Rochester, N. Y.
April 2 to 5—The American Ceramic Society, Inc., Pittsburgh.
April 12 to 15—The Electrochemical Society, Inc., Milwaukee.
April 17, 18—American Zinc Institute, St. Louis.
April 20, 21—American Institute of Mining & Metallurgical Engineers, Pittsburgh.
May 1, 2—Westinghouse Machine Tool Forum, Pittsburgh.
May 25—American Iron and Steel Institute, New York.
Oct. 5, 6—American Institute of Mining & Metallurgical Engineers, Pittsburgh.
Oct. 16, 17, 18—American Institute of Mining & Metallurgical Engineers, Cleveland.
Oct. 27, 28—American Institute of Mining & Metallurgical Engineers, Columbus, Ohio.



"Break that Bottleneck!"

Eliminate the slow-down of fumbling around hard-to-get-at spots on assemblies. Here is where the CLUTCH HEAD Lock-On feature, uniting screw and bit as a unit, substitutes seconds for minutes . . . reduces haphazard groping to a speedy, simple, and certain operation by permitting one-handed reaching and driving from any angle. This frictional lock is instantly obtained with a reverse turn of the Assembler's Bit in the recess of the CLUTCH HEAD Screw. The hold is definite; yet it is automatically released when the screw is turned for the drive home. So, too, in field maintenance, this CLUTCH HEAD Lock-On feature bypasses the bottlenecks to save time by simplifying repair and adjustment operations. With a Center Pivot hand driver, service men find it easy to *withdraw and save* CLUTCH HEAD Screws for re-use, undamaged and held securely against dropping and loss. Similarly, the long reach through the bottleneck frequently saves the dis-assembling of surrounding units for access to points beyond.

Would you care to personally inspect and test the many exclusive advantages of CLUTCH HEAD *Screws? Then let us send you package assortment along with sample Center Pivot Bit and fully illustrated Brochure.*

This is the only modern screw operative with Assembler's Bit or ordinary type screwdriver. It is available in Standard and Thread-forming types for every purpose... with features that contribute definitely to smoother and lower cost assembly line operation.

CLUTCH HEAD SCREWS

Note the economy of this rugged Center Pivot Assembler's Bit. It delivers a longer uninterrupted spell in operation and requires only a brief application of the end surface to a grinding wheel to restore its original efficiency.

KEYSTONE

Wire

As easily and quickly as a mother lifts a baby from a cradle, this mobile crane, equipped with strong wire cables, unloads a huge slingfull of vital army rations from an amphibious "Duck". Here again, WIRE fulfills an important role on the fighting fronts—helping deliver *food* to our fighting men. This is but one of thousands of ways in which wire production is adding impetus to the invasion.

But even though most of our present industrial wire production is working for Victory, we are making preparations for the postwar market. Because of many new uses for wire and vastly improved fabricating techniques, we suggest you consult our engineers immediately regarding the use of wire in *your* civilian products.

Priority Changes

L-30-b—Dir. 1 authorizes production of approximately 500,000 enameled cold pack canners. (2-19-44)

L-54-c—Amended order permits resumption of production of check, coin, envelope, currency, postal, and stamp machines to meet essential requirements. (2-26-44)

L-65-a—Order permits production of domestic electric flat irons for civilian use to be resumed on a limited basis in plants where labor is available and where there will be no interference with existing or potential war contracts. (2-24-44)

L-65—Amended order brings references in application forms, used by manufacturers in requesting permission to ship resistance wire and commercial cooking appliances, up to date through minor revision. (2-19-44)

L-145-a—Amended order places additional production controls on the output of large size ball bearings. (2-19-44)

L-154—Sched. II, as amended, lifts restrictions on the use of copper and copper base alloys that have limited the inclusion of these metals in the manufacture of tube and tube sheets of steam condensers. (2-21-44)

L-197—Dir. 1 relaxes the prohibition against the use of steel drums for shipping molasses. (2-23-44)

L-222—Amended order requires manufacturers and distributors of floor sanding and finishing machines to file a monthly report on production and shipments where production is scheduled. (2-19-44)

L-236—Sched. III, as amended, removes restrictions on the use of metals in the manufacture of marine fittings hardware. Action permits the use of alloy steel instead of carbon steel where necessary. (2-26-44)

L-237—Amended order raises the inventory limit of light power-driven tools to eight of each size and type for dealers in 17 Western states. (2-26-44)

L-298—Amended order rules that applications for the purchase of resistance welding equipment will continue to be accepted on Form WPB-2752 only until March 15. Thereafter applications must be submitted on Form WPB-1319. (2-25-44)

L-327—Order restricts the manufacture of lighting equipment for aircraft to equipment certified by the Aeronautical Board, Army Air Forces, Bureau of Aeronautics of the Navy, or the Civil Aeronautics Administration. Order effective April 10. (2-26-44)

M-9—Dir. 2 permits users of small amounts of copper raw materials to obtain in any calendar quarter materials containing up to 150 lb. of copper without obtaining WPB authorization. (2-22-44)

M-11—Amended order simplifies allocation procedures for slab zinc, but does not relax restriction on its use, however. (2-19-44)

M-225—Order dealing with overhead traveling cranes has been revoked. (2-19-44)

M-227—Amended order permits delivery to be made in any calendar quarter of 75 lb. or less of cuprous oxide to each laboratory or supplier principally engaged in supplying laboratories. (2-24-44)

P-19-h—Int. 1 points out that authorizations on CMPL-224 or GA-1456, the form in present use, is the equivalent of a P-19-h authorization as far as the delivery of restricted items for construction is concerned. (2-17-44)

P-68—Amended order clarifies the meaning of several provisions relating to MRO supplies for producers of iron and steel. (2-25-44)

P-98-b—Revised order extends to oil operators who provide maintenance and repair service to retail and consumer outlets the right to use an AA-3 rating. (2-24-44)

P-98-e—Revised order extends to oil operators who provide maintenance and repair service to retail and consumer outlets the right to use an AA-3 rating. (2-24-44)

Dir. 5 of Reg. 3, as amended, makes changes in phraseology for the purpose of clarification, and prohibits the extension of AA-1 and AA-2 blanket MRO ratings to secure production materials on the list attached to the direction. (2-18-44)

Reg. 18 has been amended to bring rules governing the freezing of production, delivery, and shipping schedules into conformity with Order M-293, as amended. (2-24-44)

REINHOLD BOOKS

of Unquestioned Authority in the Metallurgical Field

METALS and ALLOYS DATA BOOK—*By Samuel L. Hoyt.* Here—between two covers—are the records of *all* metal properties. 340 tables of engineering property data on both common and rare metals and alloys. Specially arranged for easy reference, indexed alphabetically as well as by subject. A book to USE . . . not a thesis.
350 Pages.....340 Tables.....Illustrated.....$4.75

TUNGSTEN—Its History, Geology, Ore-Dressing Metallurgy, Chemistry, Analysis, Applications and Economics.—*By K. C. Li and Chung Yu Wang.* Meets the need for a comprehensive treatment of the geology, processing and uses of this strategic metal. The occurrence, composition and preparation of tungsten ores; its uses, chemistry and economic aspects—all are discussed. Includes maps, illustrations, color reproductions. Authoritative, up-to-the-minute.
325 Pages .....A.C.S. Monograph No. 94 .....$7.00

BERYLLIUM—Its Production and Application.—*By Zentralstelle für Wissenschaftliche-Technische Forschungsarbeiten des Siemens-Konzern. Translated by Richard Rimbach and A. J. Michel.* Only book in English on beryllium. Articles by leading specialists on analytical chemistry of beryllium, its thermal reduction, production, production of alloys by electrolysis, theory, properties and effects of age-hardening, conductivity, density, etc. 198 diagrams and photomicrographs.
331 Pages .....Illustrated $10.00

A COURSE IN POWDER METALLURGY—*By Walter J. Baeza.* Production of metal powders; specifications; classification of particle size; cohesion; manufacturing problems; experiments, precautions, results. Indexed.
212 Pages ..... Illustrated $3.50

SHEET STEEL and TIN PLATE—*By R. W. Shannon.* Complete presentation of industrial iron production in general and sheet steel and tin plate in particular. Describes industrial processes, various refining processes, application, uses, grades and finishes, with voluminous notes, appendices, bibliography and index.
285 Pages .....Illustrated.....69 Figures.....$2.50

ALUMINUM PAINT AND POWDER — *By J. D. Edwards.* Comprehensive, concise, authoritative coverage of these important substances. Manufacture of aluminum powder; its properties; composition of aluminum paint; uses. With appendix and indexes, alphabetical and by subject.
216 Pages ..... 78 Illustrations $4.50

CONDENSED CHEMICAL DICTIONARY—Third Edition (1942). Compiled and Edited by the Editorial Staff of the Chemical Engineering Catalog. Francis M. Turner, Editorial Director. Thomas C. Gregory, Editor.
Unrivaled in completeness. Important, up-to-date information on chemical and metallurgical substances not available elsewhere in book form.
756 Double Column Pages.....18,000 Items $12.00

SILVER IN INDUSTRY—*By L. Addicks.* Sponsored by the government's Silver Research Project and many important firms in the field, contains articles by recognized experts. Alloys; bonding; coatings; contacts; resistance; catalytic effects; statistics of consumption; summary; conclusions, appendices, bibliography and indexes.
636 Pages .....Profusely Illustrated $10.00

SAMPLING AND ANALYSIS OF CARBON AND ALLOY STEELS—Prepared by the Chemists' Committee of the Subsidiary Companies of the U. S. Steel Corporation. Includes approved procedures for sampling mill products, and for determining all the elements that may occur in steel under any conditions of combination.
356 Pages ..... 20 Figures $4.50

CORROSION RESISTANCE OF METALS AND ALLOYS—*By R. J. McKay and R. Worthington.* Exhaustive study of every known form of corrosion from every source. Bibliography. Indexed by subject and author.
492 Pages.....A.C.S. Monograph No. 71.....66 Figures.....313 Tables.....$7.00

PROTECTIVE COATINGS FOR METALS—*By R. M. Burns and A. E. Schuh.* This important and far-reaching subject is so comprehensively covered that this book forms a reference work invaluable to anyone in the metallurgical field.
407 Pages.....89 Figures.....A.C.S. Monograph No. 79.....$6.50

TIN, ITS MINING, PRODUCTION, TECHNOLOGY AND APPLICATIONS—*By C. L. Mantell.* Its properties, production, distribution, and consumption; alloys, compounds, corrosion. Indexed.
366 Pages ..... A.C.S. Monograph No. 51.....91 Figures.....$5.25

New Metallurgical Technique Shown in Enemy Patents

• • • This is the sixteenth list of seized enemy patents available on license from the Alien Property Custodian. These patents are grouped in classes. In the following lists, subclass numbers are shown first in parentheses, followed by the patent number, description of the patent, the inventor's name and nationality, and the date the patent was issued.

This series began in the Nov. 4 issue of THE IRON AGE, page 95, at which time rules and procedures for obtaining the patents were described along with full information about their usage and possibilities. Seized patent applications were listed in THE IRON AGE on July 8.

Class 75—Metallurgy

1,728,909. Method of making tools from hard-metal alloys produced by sintering. K. Schroter, Germany. 9-17-29.

1,757,846. Manufacture of bodies for tools and the like from materials such as carbides, the alloys thereof, and the like. K. Schroter and Hans Wolff, Germany. 5-6-30.

1,773,793. Permanent magnets characterized by the fact that they are produced from steel alloys. C. Sattler, Germany. 8-26-30.

1,774,849. Hard alloy for tools and the process for their production. K. Schroter, Germany. 9-2-40.

1,812,811. Sintered hard metal alloys and articles made thereof, such as tools and implements, which alloys do not show pores in the fracture, in, for instance, a fifty-fold magnification. B. Strauss, Germany. 6-30-31.

1,895,959. Hard alloys for the manufacture of tools and implements. C. Agte and Kurt Moers, Germany. 1-31-33.

(.50) 2,179,810. Production of magnetic substances in finely divided form, the particles of which are characterized by a very small and uniform grain size. R. Brill and K. Schoenemann, Germany. 11-14-39.

(1) 1,721,416. Compositions comprising hard metal carbides. K. Schroter, Germany. 7-16-29.

(1) 1,729,697. Process of roasting iron carbonate ores. A. Apold and H. Fleissner, Austria. 10-1-29.

(1) 1,828,756. Process for the refining of chromium ores by treating the same at temperatures about 100 deg. C. with an alkali in the absence of oxygen. P. Weise and F. Specht, Germany. 10-27-31.

(1) 1,946,231. Process for the manufacture of alloys of precious metals which are amenable to heat treatment. L. Nowack, Germany. 2-6-34.

(1) 1,949,082. Method of obtaining heavy-metal beryllium alloys. E. Pokorny, Germany. 2-27-34.

(1) 1,973,441. Sintered hard metallic alloys for use in forming implements and tools. K. Moers, K. Schroeter and H. Wolff, Germany. 9-11-34.

(1) 1,991,912. Sintered hard metallic alloys for use in forming implements and tools. K. Schroter and H. Wolff, Germany. 2-19-35.

(1) 2,015,536. Sintered hard metal alloy suitable for the manufacture of working tools and implements. K. Schroter, K. Agte, K. Moers and H. Wolff, Germany. 9-24-35.

(3) 1,726,066. Process of converting tin ores into the form of pieces. P. Haedrich and O. Kippe, Germany. 8-27-29.

(3) 1,739,839. Process of agglomerating ore, mineral, or other matter and the product produced thereby. P. Jung, Germany. 12-17-29.

(6) 1,852,965. Process for obtaining metals from ores in a substantially pure state. C. Goetz, Germany. 4-5-32.

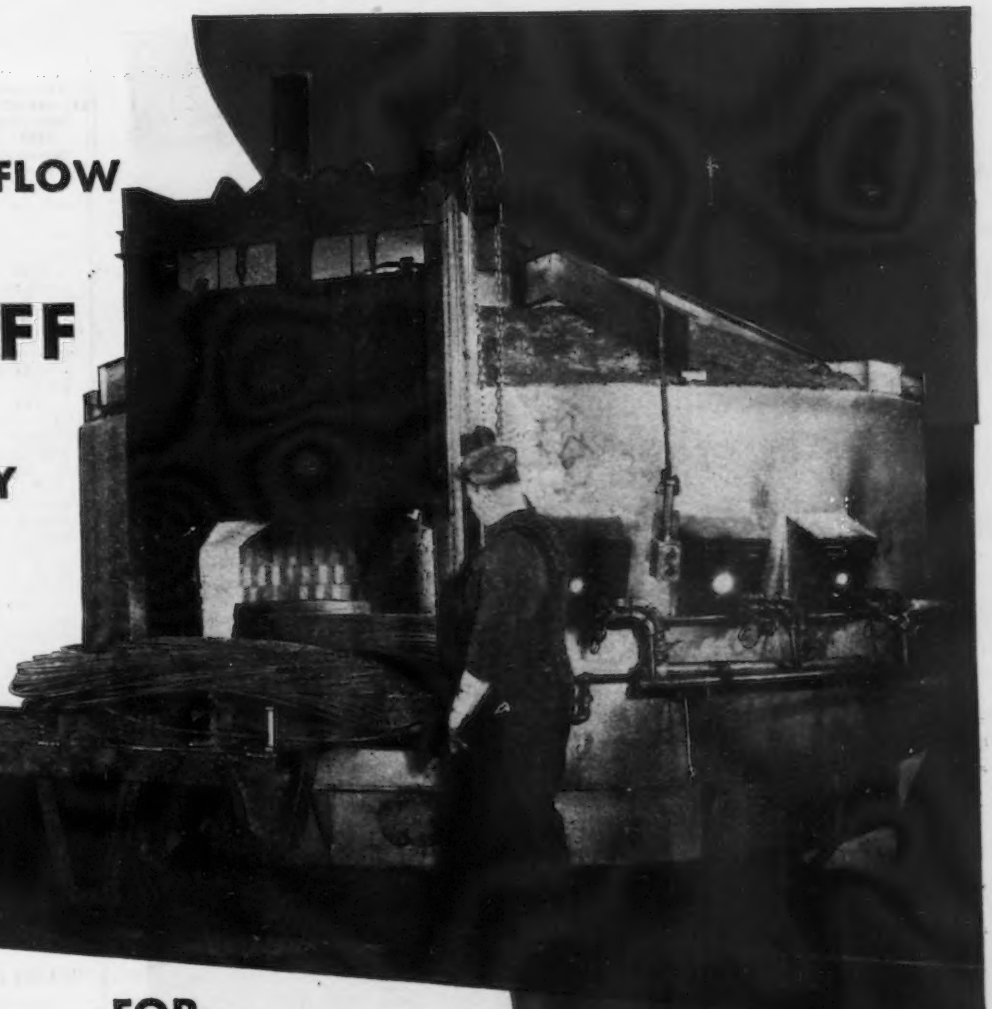
(7) 1,825,536. Process of reducing the quantity of sulphurous acid gas set free from copper glance on its roasting. M. Miyake, Japan. 9-29-31.

(7) 1,925,391. Process for the recovery of iron from iron and sulphur carrying metallurgical products especially ores. E. Kohlmeyer, Germany. 9-5-33.

(5) 2,075,210. Process for the agglomeration of fine iron ores. E. Kugener, Germany. 3-30-37.

(6) 2,045,226. Process for extracting metals

A *Steady* FLOW OF WYCKOFF CARBON AND ALLOY STEELS



FOR AMERICA'S "PUSH-ON"

Tons after tons of Wyckoff Special Furnace Treated Steel flow continuously to form America's fighting tools and equipment,— with no compromise in precision, accuracy or uniformity!

Wyckoff facilities that now serve 100% Uncle Sam's war effort, will be ready to serve you faithfully and dependably after our present war job is satisfactorily accomplished.

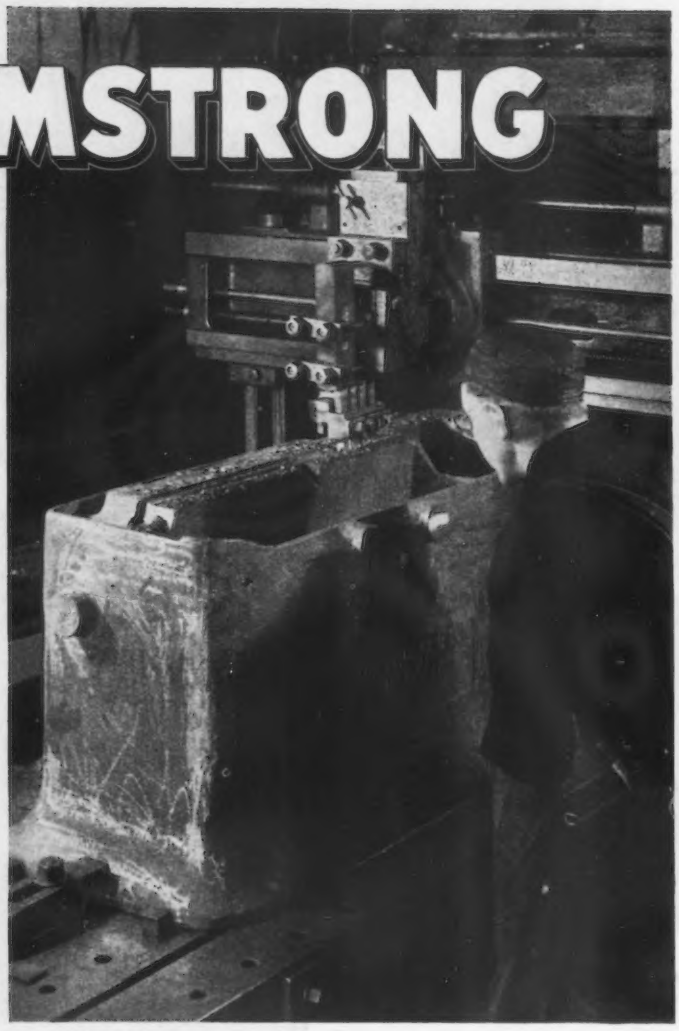
ARMSTRONG



Make each planer do the work of two . . . each ounce of high speed steel, the work of ten

• To double your output on planers use ARMSTRONG Gang Planer Tools that reduce surfacing time from 50 to 75%. To make your high speed steel go farther, use ARMSTRONG TOOL HOLDERS that "Save: All Forging, 70% Grinding and **90% High Speed Steel.**" (Tests carried out covering some of the largest plants have proven that the saving in high speed steel is even in excess of "90%").

There are ARMSTRONG TOOL HOLDERS for every operation on lathes, planers, slotters and shapers, and for many operations on turret lathes and screw machines. Each is a permanent multi-purpose tool that does the work of a complete set of forged tools. Each is a stronger, more efficient tool than can be forged and will stand up to the highest speeds and heaviest feeds. Each makes an ounce of high speed steel go as far as 10 ounces will go in a forged tool.

Use ARMSTRONG TOOL HOLDERS wherever possible. On all types of work, the heaviest as well as the lightest, they save man-hours, increase machine tool output and cut high speed steel requirements to a tenth.

ARMSTRONG BROS. TOOL CO.

from ores. C. Goetz, Germany. 6-23-36.

(6) 2,082,284. Process for extracting metals from ores. C. Goetz, Germany. 6-1-37.

(10) 1,719,657. Method of treating antimonial ores by means of the wet reduction process. H. Goldmann, Germany. 7-2-29.

(10) 1,745,464. Process for the purification of metals. F. Wever, Germany. 2-4-30.

(10) 1,881,872. Method of producing aluminum and aluminum alloys. W. Neumann, Germany. 10-11-32.

(10) 1,884,993. Production of metallic magnesium by thermal reduction with carbonaceous material of magnesium containing material such as magnesium oxide or raw material containing or yielding magnesium oxide. F. Hansgirg, Austria. 10-25-32.

(10) 1,925,292. Method of sintering metallic bodies. R. Walter, Germany. 9-5-33.

(10) 2,012,777. Method of manufacturing alloys substantially free from associated deleterious impurities of carbon, silicon, oxygen, nitrogen, sulfur, phosphorus and the like. W. Rohn, Germany. 8-27-35.

(10) 2,097,344. Process for accelerating metallurgical slag reactions in inductively heated electric melting furnaces. W. Rohn, Germany. 10-26-37.

(10) 2,099,151. Production of magnesium from magnesium oxides. A. Vogt, Germany. 11-16-37.

(10) 2,177,070. Method for metallurgical treatment of ores by high frequency electric currents. Hideyuki Kikuchi, Japan. 10-24-39.

(11) 2,071,942. Method of manufacturing iron alloys. W. Rohn, Germany. 2-23-37.

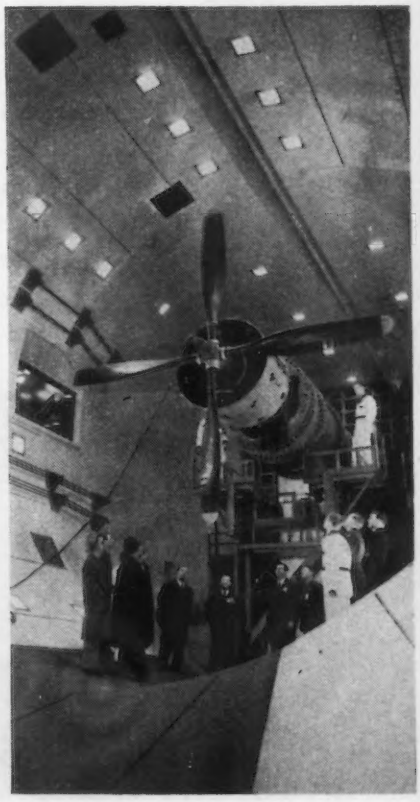
(11) 2,139,853. Method of making steel in inductively heated electric melting furnaces. W. Rohn, Germany. 12-13-38.

(11) 2,156,263. Method of manufacturing iron by direct reduction. K. Kusaka and H. Ashida, Manchukuo. 5-2-39.

(12) 1,608,270. Method for the decarbonizing of highly-carbonaceous ferro-chromium. L. Friderich and W. Rodenhauser, Germany. 11-23-26.

(12) 1,923,471. Manufacture of steel in an

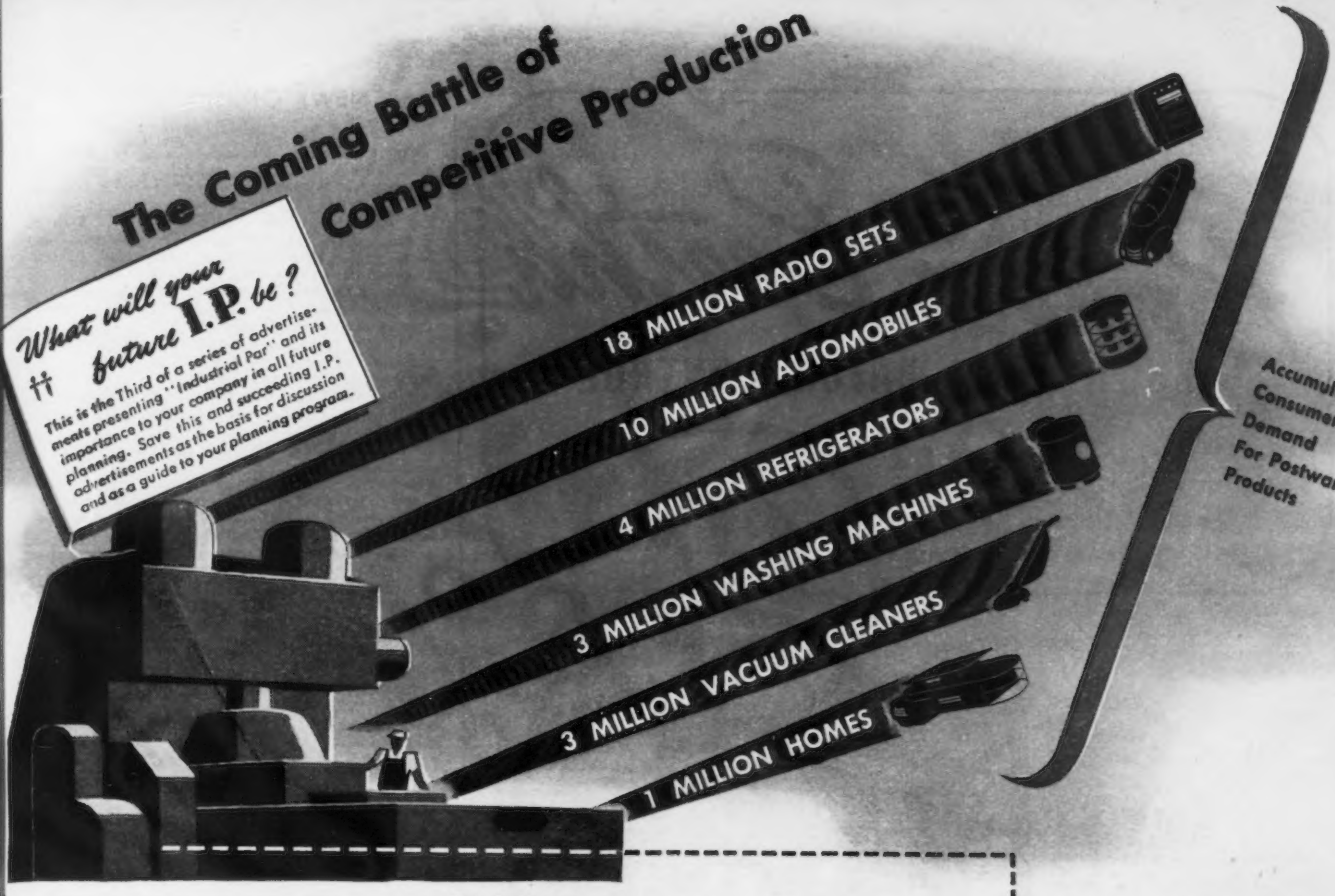
WORLD'S LARGEST: *This, the world's largest four-blade hollow steel electric propeller, 16 ft. 8 in. in diameter, will be tested at the Caldwell, N. J., plant of Curtiss-Wright. The propeller cell used can test blades for engines up to 5000 h.p.*



The Coming Battle of Competitive Production

What will your future **I.P.** *be?* ††

This is the Third of a series of advertisements presenting "Industrial Par" and its importance to your company in all future planning. Save this and succeeding I.P. advertisements as the basis for discussion and as a guide to your planning program.



will your company's I.P. qualify you to meet the Challenge

THERE'S a lot of "wants" waiting to be supplied by peacetime production. Millions of people are just marking time—with billions in money saved and ready to spend — to buy new radios, cars, refrigerators, washing machines, vacuum cleaners, homes and scores of other products as soon as they become available again.

When this flood of pent-up purchasing power breaks, American industry can expect a hard battle of competitive production. The old rule of three in manufacturing consumer goods—quality, quantity, low cost — will be in full sway again.

Manufacturing for peacetime markets will challenge managerial skill as much as manufacturing for war. Building a dominant position in these markets — finding profits — establishing the conditions for employment — will call for broad-visioned plans, able direction and execution.

To improve quality — reduce cost — and increase the output of goods, machine tools — the newest and finest — are indispensable. Machine tools are of key importance in determining your company's standing in terms of *industrial par* — the constantly increasing output per man-hour equal to approximately 50% every 10 years.

Other things being equal — quality of product, price, sales organization — the successes in the coming battle of competitive production will come to those companies best qualified to attain or excel industrial par — its vital significance as summarized in the panel headed "Spotlight Facts for Your Future I. P. Planning."

Your planning for postwar should include as a major project the matter of machine tools — provision for their continuing replacement to assure full productive capacity — to enable you to keep step with a high level of national prosperity — the volume production of more goods for more people at lowest cost and the resulting security of jobs and wages for the greatest number of workers.

Spotlight facts for your future I.P. *planning*

- ✻ Production methods — developed in wartime —increase man-hour output; pent-up buying power — released in peacetime — demands increased production.
- ✻ The rate of 2½% increase per year output per man-hour, established by a 12 year record of industrial production, can be expected to reach at least 4% per year — compounded.
- ✻ Manufacturers must set a goal of 50% increased output per man-hour every 10 years — to maintain a high level of national prosperity and achieve its benefits in terms of security of jobs and wages for the greatest number of workers and the volume production of more goods for more people at lowest cost.
- ✻ Machine tools — the most modern, most efficient — are recognized as the most effective implements of mass production and increased output at lowest cost — but only continual replacements with the newest and finest machine tools assures full productive capacity. *Such replacements yearly should be equal to 10% of the total machine tool investment — in keeping with increased output.*
- ✻ The cost of machine tools is insignificant in terms of their productive power . . . from 1927 to 1937, according to census reports, American manufacturers had only a total of about 2% invested yearly in machine tools in ratio to a total volume of 9 billion dollars' worth of production annually.

†† **Industrial Par** — *the constantly increasing output per man-hour equal to approximately 50% every 10 years.*

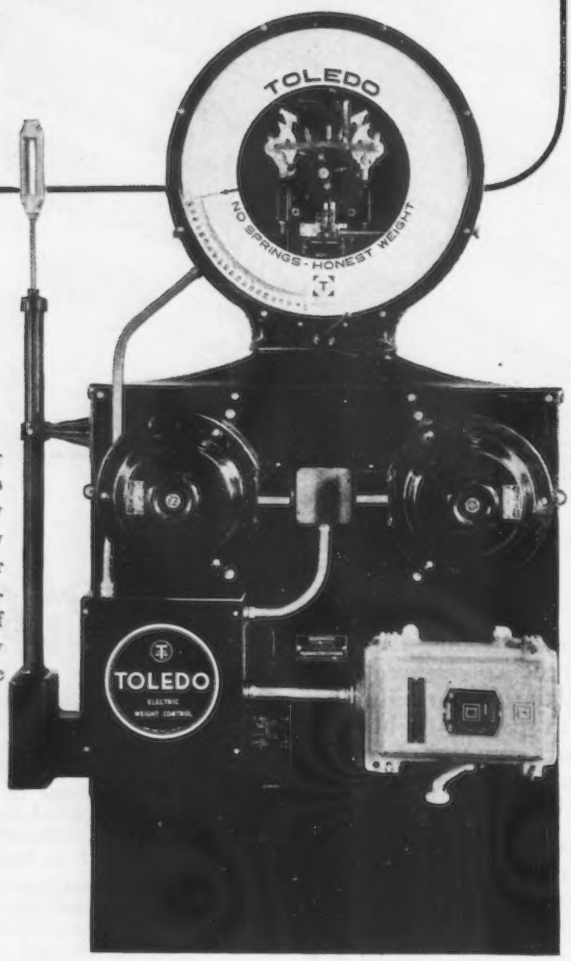
Buxom Bertha
KNOWS HER BATCH CONTROL



Our Engineers dubbed her "Buxom Bertha." In glass plants where she works they know how deft her hand, how keen her eye, how efficient her control in the automatic high-speed low-cost batching of multiple ingredients. They love her for her superlative accomplishments.

A TOLEDO *CONTROL* INSTRUMENT

● Toledo Scales weigh-count-measure-*control* both fluids and solids. So doing, they monitor production and accumulate Control Facts which are vital to the maintenance of quality and the accurate determination of costs. They are the Silent Sentinels of Production.

Behind their quiet efficiency stands TOLEDO RESEARCH —the coordinated activity of the largest engineering-research group in the scale industry.

Toledo Research, prewar, had up its sleeve many developments in the fields of applied electronics and optics, which have helped to make War Things better, and faster.

Toledo Research, postwar, will help build a better world through the more accurate and rapid measurement and control of materials . . . Toledo Scale Company, Toledo, Ohio.

TOLEDO SCALES

TIP FOR TOMORROW *PRINTED Weight Records will become universal in Industry, postwar. Hundreds of war plants are using them. We are at liberty to send you complete information now.*

electric furnace containing one or more of the metals tungsten, molybdenum and vanadium. C. Arnold, Germany. 8-22-33.

BRAKE SHOE WARS ON WEAR

Announces research group to make vital parts last longer

For years, Brake Shoe in all of its divisions has been fighting to reduce losses caused by wear; heat, friction, impact, corrosion, abrasion and stress — wear from whatever cause.

Now such activities have been augmented and strengthened by centralization of experimental engineering under the direction of a Research Group at Mahwah, N. J.

While activities of this Research Group cover a wide range of industrial problems, their immediate responsibility is to carry on relentless war on wear.

In nearly every machine there is a "punished" part — a place where wear is greatest.

Often a manufacturer's success depends upon his ability to improve that particular "punished" part.

It is Brake Shoe's business to *know* the best material for each "punished" part and *how* to produce that material economically.

If existing materials are not good enough the Research Group endeavors to design better ones.

If design is faulty, Brake Shoe engineers can offer sound suggestions for changes.

Brake Shoe focuses *on one part* the effort that the manufacturer, for cost reasons, must spread over the *whole* machine.

The result? A better product . . . often at lower cost.

The resources of the Brake Shoe Research Group — unique we believe in this country — are available to manufacturers whose production calls for large runs of standardized parts.

Is Brake Shoe on Your Parts Source List?

Because many of the millions of parts produced by Brake Shoe for war have equally important peacetime uses, Brake Shoe will be ready for parts assignments in volume, the moment victory is won!

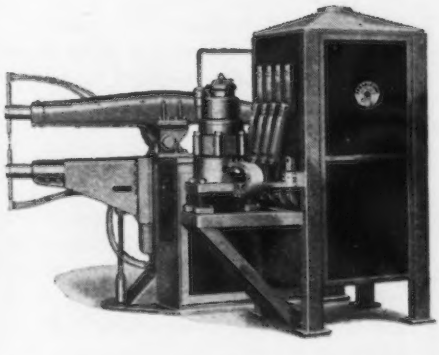
Announcing "STORAGE BATTERY" WELDERS

by PWC



The PWC STORAGE BATTERY Welder is already in use, welding aluminum for war materiel.

What a STORAGE BATTERY Welder is:

A modified PWC resistance welder (gun or machine type) with specially designed storage batteries instead of transformers or condensers . . . a simple non-arcing D-C controller-contactor (Patent applied for) . . . a continuous battery-charging low line-load instead of momentarily high power demand . . . Operated with a simple sequence weld-timer.

What a STORAGE BATTERY Welder does:

Eliminates reactance losses between power supply and electrodes . . . Eliminates inductive losses in the welding "loop" . . . Operates with virtually unity power factor . . . Eliminates high voltage "danger" . . . Provides maximum simplicity of maintenance.

What STORAGE BATTERY Welding means:

Lower cost stored energy welding equipment . . . Lower operating cost including vastly lower power cost . . . Ability to spot-weld aluminum even where power line capacity is relatively low . . . High efficiency even when welding at considerable distance from power supply . . . Less critical adjustments to get consistently good welds . . . Vastly simpler to operate.

PAGE *Stainless Steel* WIRE

• If you are planning to use Stainless Steel Wire after re-conversion—**GET IN TOUCH WITH PAGE.**

Remember, wire has *always* been the business of **PAGE.** And, even in the earlier days of Stainless Steel, **PAGE** as a supplier of Stainless Wire learned much of its working qualities.

Then came the wide range of **PAGE** Shaped Wires—Hexagons, Octagons, Triangles, Keystones, Ovals, Half-rounds—in section areas to

.250 sq. inches, and Rectangles and Flats in widths up to 3/8 inch.

All this activity brought more knowledge of the workability of Stainless Steel.

Then came 1941—and war—with a tremendous increase in the use of Stainless Steel that has made this entire organization perfectly at home with this product.

So, again! If you are planning to use Stainless Steel Wire after re-conversion, **GET IN TOUCH WITH PAGE!**

Keep Eye on Ball, Says C. E. Wilson

• • • Charles E. Wilson, executive vice chairman of WPB, in a speech before the American Arbitration Association, on Feb. 17, said: ". . . altogether too many people, particularly in industry, are taking their eyes off the war production ball. Too many are looking ahead and casting about to find their place in the postwar parade. Postwar production is admittedly an exciting and fascinating prospect. It is natural and human that the interest of businessmen should center on it more and more — but it is also terribly dangerous and we must guard ourselves strictly against too much indulgence in postwar thinking."

Tool Engineers Plan Two-Day Session

• • • One of the most significant technical programs ever sponsored by the American Society of Tool Engineers has been announced for the annual meeting of the society scheduled for March 27 and 28 at the Bellevue-Stratford Hotel, Philadelphia. One of the innovations will be the presentation at one session of a series of papers discussing all the factors relating to the putting into production of a vital war product. Scheduled for Monday morning, the 27th, it will cover by papers presented by departmental heads of a major industrial producer, the engineering, planning for production, tooling, foundry and machining operations and inspection methods relating to this one product, thus providing an integrated picture of all the problems involved.

Monday afternoon's session will be devoted to new developments in surface finishing methods, with particular stress on honing through papers by Kirke W. Connor, president, Micromatic Hone Corp., Detroit, and A. F. Hasty of Sunnen Products Co., St. Louis.

Monday evening's meeting is devoted to the integrating of manufacturing, tooling and personnel to produce war products, with William Jack of Jack & Heintz in Cleveland revealing the principles on which this company based its production achievements as well as an analysis of the merits of the plan from a technical standpoint in terms of results achieved.

Tuesday morning's session is de-

4-High Precision Cold Mills

For Rolling Ferrous and Non-Ferrous Metals

These UNITED MILLS are used chiefly for accurate finishing of thin gauge strip. Their simplicity of design permits flexible speed operations at a low maintenance and operating cost.

They are a product of UNITED'S more than 40 years experience in the design and construction of rolling mills and their auxiliary equipment.

. . . by building standard low-cost DELTA DRILL PRESS units into this ingenious jig . . .

By hundreds of applications similar to this one at Curtiss-Wright, war industry has tested and proved a new approach to tooling which may save you thousands of dollars in converting to peacetime production:

Instead of getting along with slow, costly methods—or tying up heavy capital in complicated special machines which are slow to build and difficult to adapt — you build your own special set-ups with low-cost stock-model Delta units or batteries.

The trunnion jig in the picture is an excellent example. Equipped with two standard 14" Delta Drill Press heads attached to hinged arms on carriages, it speedily drills over 200 holes on both sides of duralumin shapes, in "matched angles" requiring extreme accuracy. (Details on request.)

For a simple, safe, satisfactory solution of widely varied production problems — with results that are creditable to all concerned — write for "Tooling Tips" and latest Delta catalog. MA-5

DELTA MILWAUKEE Machine Tools

voted to a symposium on electronics as applied to machining. One paper will be read by T. R. Lawson of the electronic control section of Westinghouse Electric & Mfg. Co., the other two by machine tool manufacturers. The first of these is by R. A. Cole, experimental engineer of the grinding machine division, Norton Co., while the second is by B. T. Anderson, of Sundstrand Machine Tool Co.

Two of the most recently spectacularly developed machining processes—fly-cut milling and broaching—form the nucleus of discussions at the Tuesday afternoon session, the former being presented by Ralph R. Weddell, president, Weddell Tools, Inc., Rochester.

The annual meeting will be brought to a close Tuesday night with a banquet at which John H. Van Deventer, editor of THE IRON AGE, is the principal speaker, discussing "The Tool Engineer and the Post War World." Ray H. Morris, A.S.T.E. president, will preside at the banquet, with past-president T. B. Carpenter as toastmaster. Installation of officers for 1944-45 will also take place at the banquet, together with presentation of the annual membership trophy award.

No show is scheduled coincident with the annual meeting, this year.

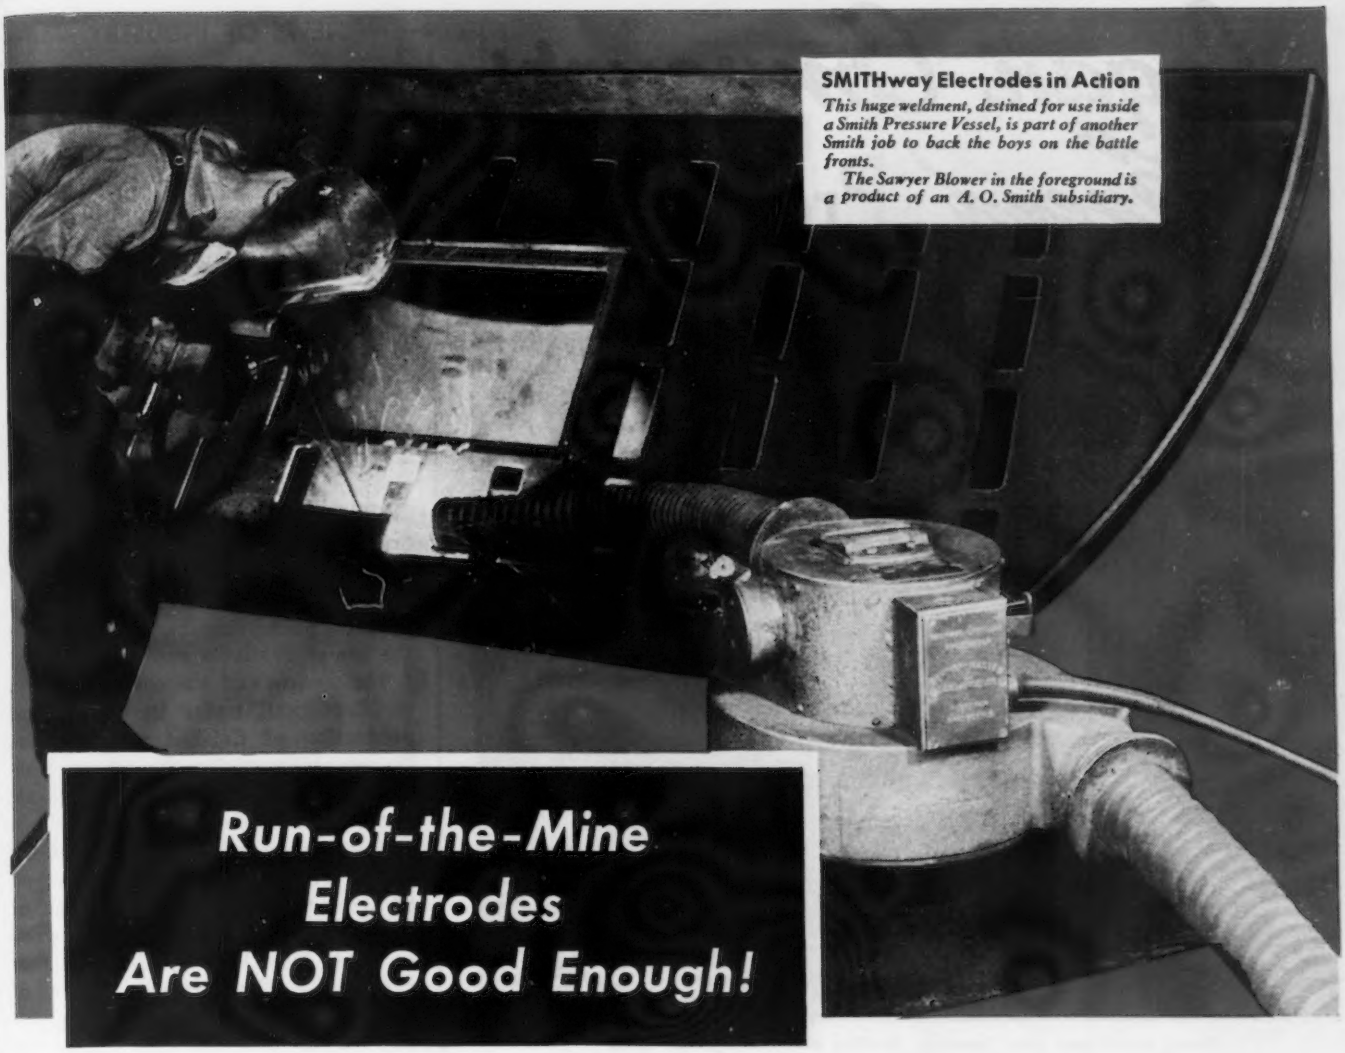
General Chairman for the annual meeting is Adolph E. Berdick, 1st vice-chairman of the Philadelphia Chapter of the A.S.T.E. and co-owner of the Engineering Tool Co., Philadelphia. A.S.T.E. 1st vice-president D. D. Burnside is in charge of the technical program, assisted by W. B. Rapp of W. B. Rapp Machining Co.

Unused Allotment Procedure

Washington

• • • **Rules governing** returns of excess or unused allotments of controlled materials have been modified to bring them into conformity with WPB's decentralized operations, the CMP division of WPB announced in Direction 26 to CMP Regulation 1.

The modified rules point out that excess or unused allotments that originate with WPB field offices should be returned to such field offices. The amended direction also points out that excess or unused allotments may be returned by letter if it is impractical for the person returning the allotment to obtain a copy of CMP-32, the form usually used to make such returns. The amendment also changes addresses of certain claimant agencies and WPB Industry Divisions, to which unused allotments are returned in order to bring them up to date.



SMITHway Electrodes in Action

This huge weldment, destined for use inside a Smith Pressure Vessel, is part of another Smith job to back the boys on the battle fronts.

The Sawyer Blower in the foreground is a product of an A. O. Smith subsidiary.

Run-of-the-Mine Electrodes Are NOT Good Enough!

SMITHway Certified Welding Electrodes were first made by us for our own use. WHY—?

Because in our plants, where practically every type of welding is done *every day* . . . run-of-the-mine electrodes were not good enough!

Many other concerns, who also demand the best in welding, now use SMITHway Certified Welding Electrodes—the same electrodes we use—the same electrodes we offer you. That's why we are confident we can prove that they will give you *better welding results* at lower time and material cost. We have already proved it—conclusively—in our own plants and in the plants of other welders.

Logan Conveyors Speed Production*

Logan double-lane roller conveyor handling aluminum cylinder heads through machining operations in the plant of the Wright Aeronautical Corporation at Cincinnati, Ohio. INSET: Assembled head-and-cylinder units, on individual pallets, flow by in a steady stream.

Smoother, swifter production flow plus important economies in time, space and man-hours — Logan conveyor systems are making these contributions to America's far-flung industrial war effort. From receiving through processing and assembly to shipping, Logan Conveyors provide a continuous supply of materials and parts to successive operations. You can benefit by Logan handling methods both during and after wartime. Write for details to Logan Co., Inc., 545 Cabel, Louisville 6, Ky.

*in Vital War Industries

Director Points To CMP Successes

• • • **Industry in the** United States today is producing more finished products for war and essential civilian purposes in proportion to available raw materials than it was prior to the announcement of the Controlled Materials Plan in November, 1942, W. C. Skuce, director of the Controlled Materials Plan Division of the War Production Board announced today.

"CMP, which went into operation April 1, 1943, is now an acknowledged success after less than one year's operation," Mr. Skuce said. "Under its procedures, materials are being distributed to industry in an orderly manner, permitting high efficiency in the use of available resources."

The measure of success is found in the fact that, under its procedures, production of finished products has shown substantially greater percentage increases than the supply of basic raw materials themselves.

For example, from the time CMP was originally announced to the end of 1943, the quarterly production of airplanes of all types increased 80 per cent, from 14,380 to 25,953 planes per quarter. The quarterly delivery of deadweight tonnage of merchant vessels increased 81 per cent during the same period, from 2,924,000 to 5,295,000 deadweight tons per quarter. The combat tank program has been consistently met since the inauguration of CMP, although it does not show the increases reflected in aircraft and merchant vessel production because of a reduction in the program itself. Combatant ship production increased 257 per cent in terms of displacement tons, from 156,506 to 559,220 tons per quarter, during this same period.

At the same time that airplane production was increasing 80 per cent and deliveries of merchant vessels 81 per cent per quarter, and deliveries of combatant ships 257 per cent, the available supply of the controlled materials had increased—but by much smaller percentage figures.

For example, aluminum supply during the fourth quarter of 1943 reflected an increase of 36 per cent over the fourth quarter of 1942, while available copper increased only 5 per cent during the same period. The quarterly supply of carbon steel increased 7 per cent from the fourth quarter of 1942 to the fourth quarter of 1943, while the supply of alloy steel decreased 21 per cent.

"Comparison of percentage in-

creases in supply of controlled materials with the increased output of major military and essential civilian and items indicates that proper channeling of materials to production has helped accelerate war output," Mr. Skuce said.

"Major accomplishments of CMP which have permitted this increased production are:

"1. Provision of realistic end-product programs which are feasible within the available supply of basic raw materials.

"2. Provision of balanced flows of materials and parts to assembly lines for final fabrication into complete items.

"Experience has demonstrated that CMP provides the mechanism for both balancing and timing war production —and consequently has aided in increasing output of war products.

"One year ago last November, the War Production Board was faced with the gigantic task of installing a new system of material distribution. This involved formulation of rules, regulations, and procedures to implement the basic idea of controlling key production materials which in turn would tend to limit production programs to available raw material supply. The principles which were originally outlined for CMP have proved the basis of the successful material distribution system which is now in operation.

"In November, 1942, U. S. industry was faced with the gigantic problem of learning and installing, in each of its many plants, the mechanism necessary for successful operation under CMP. Today, U. S. industry has completed this job."

Sylvania Electric Products, Inc., announces that work on a $100,000 addition to its tungsten plant in Towanda, Pa., will begin immediately. The plant will be owned by the DPC, but operated by Sylvania.

•

Amercoat Division of American Pipe and Construction Co., Los Angeles, has moved its Chicago sales office to Suite 341, McJunkin Building, 4554 North Broadway.

•

Kelley-Koett Mfg. Co., Covington, Ky., is now occupying a new one-story addition to its plant, which will relieve congested conditions in the plant.

•

Meehanite Metal Corp., New Rochelle, N. Y., has granted manufacturing rights for Meehanite castings to the Indian Hume Pipe Co., Wadala, Bombay, India.

•

Ohio Crankshaft Co., Cleveland, has appointed the Moore Machinery Co., Los Angeles and San Francisco, as special distributors for TOCCO Process induction heating and hardening equipment in California, Nevada and Arizona territories.

•

Tomkins-Johnson Co., Jackson, Mich., has appointed the Industrial Equipment Co., Buffalo, sales representative for its products in the Buffalo territory.

•

Kennametal, Inc., Latrobe, Pa., manufacturer of cemented carbide cutting tools, blanks, and specialties, has opened a branch office at 378 Fifth Street, San Francisco 7, for the distribution and servicing of its products in northern and central California.

•

Wheelco Instruments Co., Chicago, has been purchased by F. A. Hansen and C. H. Stevenson, vice-presidents of the Lindberg Engineering Co., and several associates. The business of the industrial instruments firm will be continued under a new corporation.

•

Aviation Corp. has established its own publicity bureau in Toledo. The bureau will be under the supervision of Arthur W. Gratop.

•

Fitchburg Grinding Machine Corp. has appointed the Rudel Machinery Co., Inc., of New York, Hartford, and Boston as their exclusive representative in the New York and New England territories.

•

Chisholm-Ryder Co., Inc., Niagara Falls, N. Y., has bought the New Way Canning Machinery Co., Hanover, Pa. The purchase will add to the company's line of food processing equipment.

•

General Electric Co., Bridgeport, Conn., is reported to have entered into negotiation with the government to take over the Lowell Ordnance Co., Lowell, Mass., which until recently was operated by the Remington interests.

•

Crosley Corp., Cincinnati, has appointed Western Merchandise Distributors, Inc., Buffalo, as its distributor in the Buffalo territory. Dutton-Lainson Co., Hastings, Neb., has been appointed distributor for the company in central Nebraska and part of Kansas.

"Look fellow, you sorta' put me on the spot—I've been in the iron and steel business for twenty years and you're the first to ask me what ferro alloys★ are. I guess the best explanation is WHY we use them. Just as mother uses certain time tested ingredients to make her cakes perfect and tasty we use certain *ferro-alloys* in the heats to give the iron and steel we make proper characteristics so it appeals to the users. So you see we can't do any guessing on ferro-alloys—*we must have quality*. In fact the advertisement that prompts your question is by the company who supplies our needs — they really have *the* consistent quality."

★ *FERRO-ALLOY: An alloy of iron with a sufficient amount of some element or elements, such as manganese, chromium or silicon, for use as a means of introducing these elements into steel by admixture into molten steel.*

WLB Refuses to Reopen Lake Carriers Wage Negotiations

• • • **The National** War Labor Board on Feb. 20 refused to reopen a collective bargaining agreement for the purpose of wage negotiations when the contract prohibited such reopening. The board, with labor members dissenting, declined to take jurisdiction over the dispute between the Seafarers International Union, AFL, with 26 Great Lakes steamship companies. The union was demanding a service bonus. The board declined to take jurisdiction since, at the time of the certification of the case to the WLB, bona fide contracts with no provision for reopening on the issue of wages were in effect.

Buffalo Proposes 90-Day War Manpower Moratorium

Buffalo

• • • **A "conditional moratorium,"** freezing war workers to their jobs for 90 days, is the newest proposal before the Buffalo-Niagara Area War Manpower Committee for preventing the exodus of men and women from vital industry. It is estimated 1500 workers are leaving war jobs monthly —900 men and 600 women—some to enter the armed services, others to seek non-essential employment.

Suggestion for the "moratorium" came from Hugh Thompson, CIO regional director, who is a bitter opponent of national service legislation or any other scheme to "draft" labor.

"I think that perhaps a 90-day conditional moratorium for workers," said Thompson, "might be the answer to the problem of war workers quitting plants. Terms would be agreed upon by labor and management.

"Basically the worker would pledge to stay on his present job for the next 90 days and the employer would agree not to lay off or fire him during that period. Other provisions would be worked out between unions and companies."

Thompson warned there was no inference of "anything along the line of national service legislation in the suggestion." Definite action on the proposal has not been taken.

SHIPPING HEAD: *Almon E. Roth was elected president of the National Federation of American Shipping, a new organization designed to provide this country with a unified, adequate post-war merchant marine. Roth comes from San Francisco.*

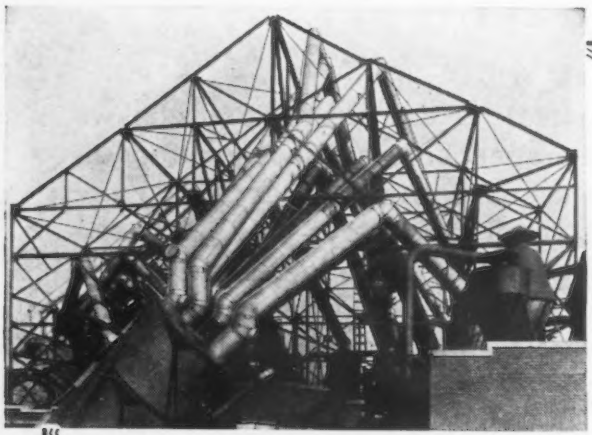
Appeal from WMC Decisions Provided in New Regulations

Washington

• • • **Unrestricted right** of appeal from decisions of the War Manpower Commission is provided in a revision of its regulation governing appeals. The changes were dictated by the Commission's experience in handling thousands of cases. The original regulation issued May 22, 1943, specifically indicated those persons entitled to appeal and spelled out under what conditions appeals could be made.

Other changes in the appeal regulation involve points which needed clarification or minor technical revision. There has been, for example, some confusion on the question of a worker's right to retain new employment obtained on the strength of a statement of availability, if the employer has appealed and it has been finally determined that the statement was erroneously issued.

The revised regulation holds that a statement of availability, once issued, stands. The employer may appeal as a matter of principle or precedent but he cannot demand that the statement of availability be withdrawn or that the worker be required to leave his new employment. In order to provide a means of reviewing the action of local employment offices before the services of a worker are lost to an employer, the revised regulation provides an optional procedure for temporary suspension of the issuance of statement of availability and making referrals in certain types of cases.



SEPARATOR of Unique Dust Collecting System, exhausting into 11-ft. steel duct 250-ft. long for bagging off. Complete system, including 50-ton steel frame, designed, fabricated, installed by Brandt.

Small Parts or Big Installations—

Installment Buying of Heavy Industrial Equipment Predicted

New York

• • • Use of installment financing in the purchase of commercial and industrial equipment promises to contribute much toward meeting the post-war problems of reconversion and expansion. Its extensive use by industrial and commercial concerns appears probable because the procedure makes it possible for the machinery or equipment to be paid for out of income which it helps to produce. This lightens the burden on the purchaser, and enables the financing agency to carry a minimum risk during the pay-out period because of the systematic reduction in the amount of debt involved. These findings are included in a report issued by the National Bureau of Economic Research, Inc.

On the basis of past experience it is likely that the greatest use of installment financing of equipment will occur among small and medium-sized manufacturing companies and in the service trades, where business units are typically small and frequently undercapitalized.

In its survey of the growth of equipment financing for commercial and industrial concerns the National Bureau states that the technique has developed as a result of the increasing mechanization of manufacturing, mining, and construction industries plus the pressure that competitive conditions have placed upon many concerns, unable to finance purchases of machinery on any other basis to modernize their processes.

In its first stages, equipment financing was promoted by non-bank agencies specialized to cope with unique credit problems. Later, commercial banks entered the field, as have insurance companies, industrial banking companies, and public lending agencies. It has been estimated that at the end of 1940 equipment financing agencies held receivables of about $400 million. This total is estimated to have increased to $470 million by the end of 1941. In addition, at the end of 1940 manufacturers themselves carried $125 to $200 million of instalment receivables originating in their sales.

Terms of the instalment payment contracts are determined mainly by the type of equipment financed and the credit standing of the purchaser. Where contracts are discounted by a financing agency with liability for them assumed in whole or in part by the vendor of the equipment, the terms of credits may be affected also by the financial responsibility of the vendor and by the type of recourse arrangement which is entered into.

Reports received during 1940 from

PIPELINE TERMINAL: *This is the terminal of a pipeline constructed and put into operation in one week so that Allied forces in Italy would have a constant flow of oil. Here, near the front, Jerry cans are filled prior to final distribution.*

THIS 24" x 32" WALL CHART GIVES ROCKWELL, BRINELL, SCLERO, VICKERS HARDNESS AND TENSILE STRENGTH CONVERSIONS

• If you are a production executive whose responsibility includes the hardness testing of metals, you will certainly want one of these new charts for your office, shop, or laboratory. Handsome in appearance, printed in three colors, with the very minimum of advertising, it will prove its value every hour of every day. Type is large, easily read at a distance of several feet, yet the chart itself is only 24" wide and 32" high—about the size of a calendar.

Although a chart like this is relatively expensive to produce, and the quantity is rigidly limited, a copy is yours—free for the asking—if you request it on your letterhead.

Write Dept. IA, CLARK INSTRUMENT, INC., 10200 Ford Road, Dearborn, Michigan.

CLARK

TOMORROW'S ACCURACY TODAY

CLARK

HARDNESS TESTER FOR "ROCKWELL" TESTING

169 different manufacturers and distributors with regard to the face amounts of contracts which they originated revealed that for 141 of these the majority of contracts amounted to $5000 or less. Down payment percentages averaged around 33 1/3 per cent. Some installations, however, were reported as carrying down payments of 50 per cent, some 10 or 20 per cent. Down payments on heavy machinery were frequently lower than those on more easily repossessible machinery of low unit value, indicating that the buyer's credit standing might in such cases be a primary consideration in fixing contract terms.

The repayment period is clearly related to the cost and expected service life of the equipment and thus varies widely. Equipment and fixtures sold to service industry concerns most often required repayment in 24 to 36 months; longer terms of 48 or even 60 months frequently were reported on sales of heavy equipment of large unit value.

OPA and WPB Form More Industry Advisory Committees

Washington

• • • **Appointment of** an Industry Advisory Committee for Gray Iron Castings composed of 11 foundry executives, was announced recently by OPA. The committee, which will be ready to confer with OPA officials whenever pricing matters in the gray iron castings field arise, held its initial meeting at the Hotel Morrison, Chicago, on Feb. 25 and 26.

Members of the committee are: Walter Chadwick, president, Davenport-Besler Corp., Davenport, Iowa; O. R. Culling, president, Carondelet Foundry Co., St. Louis; H. L. Edinger, president, Barnett Foundry & Machine Co., Irvington, N. J.; C. C. Ford, contracting engineer, G. C. Christopher & Sons Foundry, Wichita, Kan.; R. E. Kucher, vice-president, Olympic Foundry Co., Seattle; C. B. Magrath, president, Greenlee Foundry Co., Chicago; F. H. Rayfield, vice-president, Potter & Rayfield, Inc., Atlanta; A. B. Root, vice-president, Hunt-Spiller Mfg. Co., Boston; S. D. Russell, president, Phoenix Iron Works Co., Oakland, Cal., and W. S. Thomas, superintendent, Foundry Division, North Bros. Mfg. Co., Philadelphia.

The Office of Industry Advisory Committees, WPB, on Feb. 12, announced the formation of the Safes and Insulated File Industry Advisory Committee. George M. Chandlee, Consumers Durable Goods Division, has been appointed the Government Presiding officer.

Members of this committee are: Stanley R. Akers, Meilink Steel Safe Co., Toledo; E. V. Flaherty, Herring-Hall-Marvin Safe Co., Hamilton, Ohio; Harry H. Lynn, Mosler Safe Co., Hamilton, Ohio; C. E. Mann, Schwab Safe Co., Lafayette, Ind., T. E. Miller, Shaw-Walker Co., New York; A. J. Roos, Diebold, Inc., Canton, Ohio; A. N. Seares, Remington-Rand, Inc., Buffalo, and I. Laucks Xanders, York Safe & Lock Co., Baltimore.

COPPER PENNY RETURNS: *First shipment of .50 caliber cartridge casings arrive at the Denver mint. Cartridge cases will be remelted with zinc and copper for use in copper one-cent pieces. Bruce B. LaFollette, chief assayer, (left) and Elry J. Wagor, superintendent of melting and refining, examine portion of the initial shipment.*

Ms

HOUGHTON HAS THE SALT*!

Mf

Metallurgists have generally welcomed new salt bath quenching procedures as being most helpful in reducing residual strains and stresses.

"Interrupted quenches require a salt which will possess these characteristics: Fast quenching speed through the critical • Low melting point • Wide working range • High thermo-conductivity • Stability—non-sludging, unharmful to steel surfaces • Fluid, to lower carry-away loss • Easy cleaning.

Houghton's Mar-Temp Salt has been developed specifically to meet these needs. Originally named because of its application in the new Martempering process, it is equally applicable to austempering and the "isothermal" method.

Your inquiries for details and prices on Mar-Temp Salt will receive prompt attention. Ask The Houghton Man, or write

E. F. HOUGHTON & CO.
303 W. Lehigh Ave., Philadelphia 33, Pa.

Contract Termination Included in Senate Bill

Washington

• • • **With minor changes,** Senators James E. Murray and Walter F. George introduced an omnibus termination bill recently carrying out recommendations made in the report of the George Postwar Committee. Other recommendations with respect to the Office of Demobilization and disposal of surplus property and plants are not included.

The bill sets up an Office of Contract Termination Settlement and a Contract Settlement Advisory Board consisting of the heads of the principal procurement agencies.

The Director of the Office of Contract Termination is permitted to make settlements on the basis of actual, standard, average, or estimated costs, or of a percentage of the completion of work under the terminated contract, or of other methods which he deems appropriate. Company wide and direct settlements are permissible.

Fabricators Ask Separate WLB Wage Hearings

Pittsburgh

• • • **More than 700 steel** fabricators and miscellaneous manufacturers of steel products are attempting, it is said, to have their own WLB panel hear their briefs and arguments in the steel union wage case, as opposed to being included with the 150 basic iron and steel companies. It is also understood that the steel foundry and iron foundries are also taking the position that they should have their own panel.

The steel fabricators and miscellaneous groups argue that their competitive conditions are different than basic steel, and, hence, the WLB should take this into consideration by separate hearings. The 22 demands of the CIO do not, in whole apply to their industry, it is claimed. There seems to be strength to the report that these smaller companies will also insist that any increase granted by the WLB, as a result of USWA demands, should be of smaller proportions than any which might be granted to basic steel. The unions position on this probably will be a flat request that the same increase, if granted, should be made to all steel workers covered by union contracts, regardless of the type of manufacture.

Truck Cleaning Expedited by Gadget of Army "Idea Man"

Washington

• • • **A high pressure hose** that expedites and simplifies the cleaning of mobile equipment of his engineer aviation battalion in England is the product of the ingenuity of Sgt. John P. Larsen of Long Island, N. Y., the War Department announced.

Working with salvaged materials, Larsen fitted a long steel pipe with a tapered nozzle and two connections for compressed air and water. Air is fed into the contrivance from a compressor and the water is injected from the most convenient spigot. The air forces the water through the nozzle at any desired pressure, greatly facilitating the task of cleaning trucks and heavy construction equipment. An oil solution is substituted for water when tar and other such substances must be removed.

F. M. Connell Appointed Canadian Metals Controller

Ottawa

• • • **C. D. Howe,** minister of munitions and supply, announced the appointment of F. M. Connell, Toronto, as metals controller, to succeed G. C. Bateman, who was recently appointed deputy member of the Combined Production and Resources Board. Bateman becomes associate metals controller and retains responsibility for handling international problems relating to metals, including dealings with Allied Governments in connection with aluminum. D. B. Davis, of Ottawa, has been appointed deputy metals controller and G. C. Monture, Ottawa, formerly executive assistant to the metals controller succeeds S. D. Pierce of Montreal as executive officer representing Canada on the C.P.R.B. H. J. Clarke of Toronto, who was chief of the allocations division, metals control, has been appointed executive assistant to Mr. Connell, and also succeeds Monture as alternative to J. H. Berry on the Crown Assets Allocation Committee.

Renegotiation Reserves

Washington

• • • **Reserves for renegotiation** refunds which war contractors may set up and show in their statements and annual reports are not to be regarded by government renegotiation officials as binding on contractors, according to a ruling by the Joint Price Adjustment Board, representing the six federal renegotiation agencies, it was announced Feb. 19.

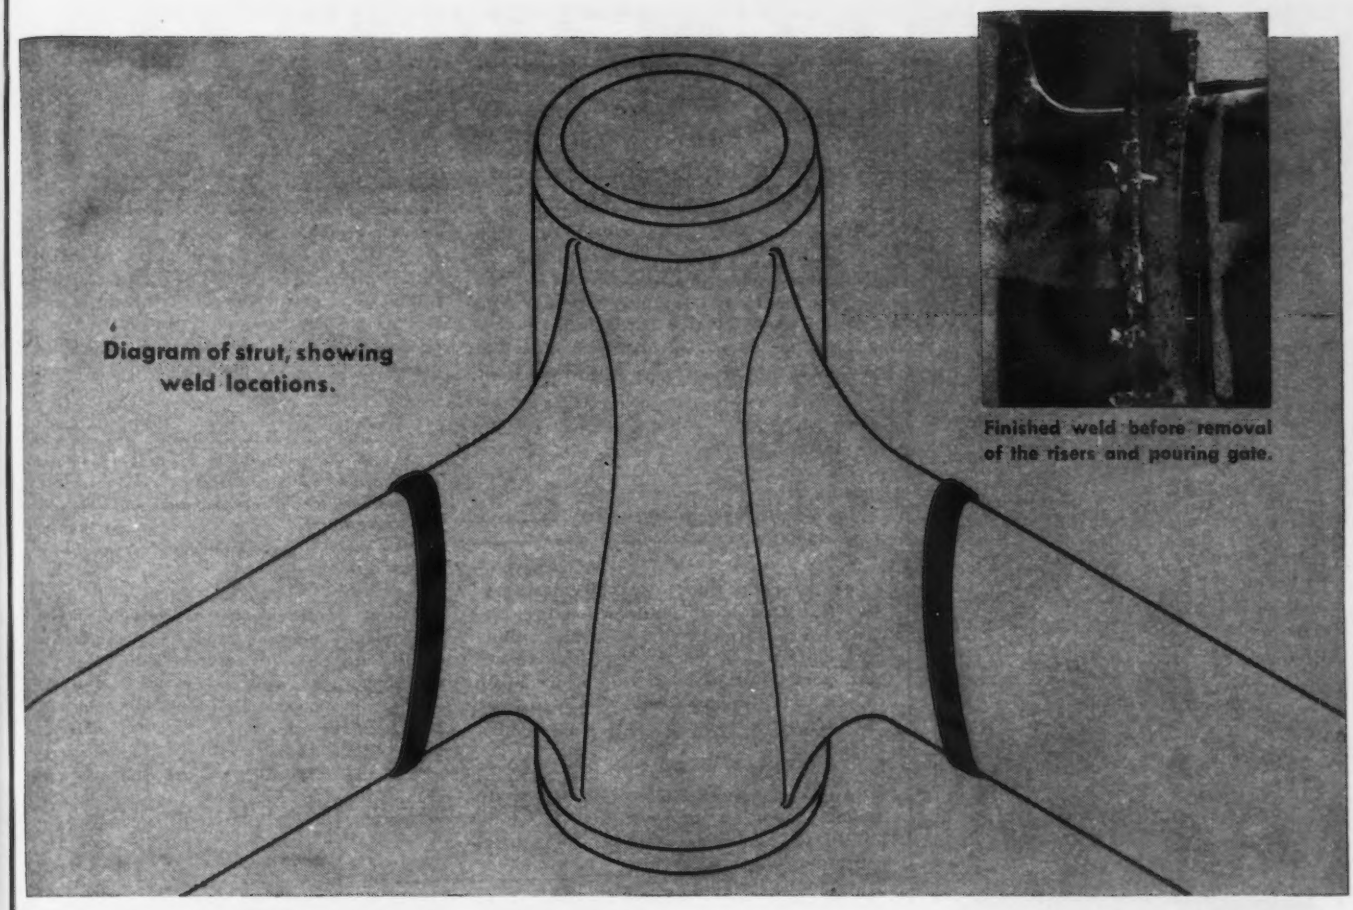

Diagram of strut, showing weld locations.

Finished weld before removal of the risers and pouring gate.

STERN STRUTS SPEEDILY BUILT BY *Thermit Welding*

Long used for the repair of heavy parts, Thermit welding is finding increasing application in the fabrication of large, heavy units from smaller and more easily transported castings, forgings and flame cut shapes.

An interesting example, illustrated above, is the fabrication by Thermit welding of stern struts for twin-screw ships. Only three days were required from the time workmen began preparing the mold for the first weld until both welds were completed, stripped of excess metal and ready for inspection. The mold for the second weld was prepared while the first weld was preheated. Pouring of the Thermit metal for the two welds took place within 24 hours.

Thermit welding obviates delays due to the unavailability of casting facilities for very large parts. Imperfections which may occur in larger castings and which result in rejection and consequent further delay need no longer be a source of concern. In point of fact, Thermit welding produces welds which are even stronger than the original castings of the same cross-section. As only one shrinkage is involved, serious local stresses do not develop...thus making stress relieving unnecessary.

For more complete information, send for 30-page booklet "Thermit Welding" describing many applications for both fabrication and repair of heavy parts.

METAL & THERMIT CORPORATION

HOBART
"One of the World's Largest Builders of
Arc Welders"

Briefly Told—

• A half lb. of boric acid and 1 lb. of borax mixed in 1 gal. of water and heated to 130 to 140 deg. F. makes a fireproofing solution for cotton that will withstand a blowtorch, according to Thomas D. Cole, president of the Lockport (N. Y.) Cotton Batting Co. The firm is using the inexpensive process to make millions of pounds of insulation for war housing.

•

• *More than 20 plants in Upstate New York are producing parts for the Army's amphibious truck called the "duck," according to Col. Frank P. Atwood, chief of the Rochester Ordnance District. Duck production is being accelerated.*

•

• Old timers at the Harley-Davidson Motor Co., Milwaukee, smile when they see the 1944 government quota which allots 2130 motorcycles for essential civilian use and export purposes and that has to be shared with Indian. Harley is scheduled for 50,000 two-wheelers this year, all for armed forces.

•

• The Wisconsin Supreme Court recently handed down an unusual decision which upheld the previous decision of a Circuit Court judge allowing a judgment of $797, double the amount claimed as damages for payroll deductions on account of faulty workmanship. The suit was started by an employee of the Oshkosh branch of the Timken-Detroit Axle Co. on behalf of himself and 74 other employees. The firm claimed actually no deductions were made because the piece work agreement called for "completed and usable pieces".

•

• "It is satisfying to note that the Baruch report lays special emphasis on the need for orderly handling of contract cancellations and production revisions, to insure successful completion of our war effort," said WMC chairman Paul V. McNutt. "From the standpoint of the nation's manpower, it is believed that unless clearcut controls are established in dealing with these changes, there will be not only confusion, but also waste of sorely needed human resources. Fundamental to these controls is the recognition that we must protect the manpower balance in areas in which there are to be cutbacks."

•

• In a paper read at the annual meeting of the American Institute of Mining and Metallurgical Engineers, E. C. Wright discussed the development of "killed" bessemer steel. The "killing" process outlined was one in which the blown convertor bath is treated by additions of hot metal containing 4 per cent carbon, as well as some manganese and silicon. The bessemer heats so treated were found to be thoroughly "killed" and of good forging qualities. They could be teemed into regular hot-top ingot molds, rolled into tube rounds and satisfactory seamless tubes with practices equaling results obtained on open hearth steels. The seamless pipe process, which involves piercing of solid billets to produce a pipe of uniform wall thickness, is in itself a very difficult forging operation and requires a billet of uniform density and forging characteristics.

•

• A new type of refractory brick for open hearth steel furnaces is being tested by Electro Refractories & Alloys Corp., Buffalo, at its Lackawanna plant. It is believed the new brick will increase steel production per furnace by as much as five per cent. The company also has developed a new type of abrasive wheel for grinding tungsten carbide tools without burning them.

•

• ***Six large war plants in Buffalo are co-operating with the Smaller War Plants Corp.'s local office to aid small industries by subcontracting. Meeting fortnightly, the committee will give special attention to urgent cases where subcontracting might prevent small plants from closing due to cutbacks.***

•

• Detroit led the nation in volume of major war supply contracts and facility projects placed during the period from June, 1940, to the end of 1943, according to WPB statistics cited by the Chicago Association of Commerce. The Michigan automotive center's contracts totaled $12,526,528,000. The Chicago metropolitan district was second with contracts valued at $8,692,674,000; Los Angeles held $8,504,064,000; Newark-Jersey City, $8,358,175,000; and New York City, $4,963,464,000. The figures do not include contracts valued individually at less than $50,000, nor do they take into account food contracts, in which Chicago captured a major bounty. A government investment in Chicago in the construction of facilities during the period was $981,181,000, of which $881,371,000 went into industrial plants and $99,810,000 into non-industrial projects.

•

• The WPB is making a serious effort to impress New England with the current and expected increases in military, Lend-Lease, and essential civilian demand for heavy construction machinery. In this connection, a WPB officer says: "Since 90 per cent of all new equipment is now needed overseas, the bulk of essential construction work at home is being carried on with used equipment. Practically all new equipment, as well as some used equipment, will without doubt be needed overseas as military operations expand and additional territory is reclaimed from the Axis. This means we cannot afford the luxury of idle equipment, stored away and waiting for peacetime work. Cranes, shovels, motor graders and tractors are especially needed." Provision has been made by the Bureau of Internal Revenue to permit, under certain conditions, deductions from profit taxes on sales of such equipment. Arrangements for these provisions have been worked out between the WPB and the Treasury.

•

• On Feb. 16, a Boston office of the Bureau of Labor Statistics of the U. S. Department of Labor was set up. Its purpose is to collect and disseminate factual and statistical data in the price, wage, and employment fields, to have available regular statistical service to the OPA, WLB, and any other federal agency desiring such data. In addition, studies of post-war employment projects for selected communities for a few New England areas will be made.

January Order Backlogs Estimated to Be $174,000,000

Cleveland

• • • **A drop of more** than 50 per cent in new order volume is reported by the National Machine Tool Builder's Association for December, 1943, as compared with December, 1942, and a sizable decline from the November's booking was also reported.

New orders in December covered 8717 units valued at $32,296,864, which compares with 17,884 units valued at $73,226,864 in December, 1942, and 10,240 units valued at $37,610,773 in November, 1943. The projected estimate of new machine tool orders recorded January of this year is about 8600 units probably totaling $29,500,000.

Cancellations in December affected 665 units valued at $5,830,023, which compares with 1398 units of $6,111,515 in November and 3060 units valued at $21,227,461 in December, 1942.

Shipments in December, 1943, totaled 12,646 units at a dollar value of $58,945,893 as compared with 13,819 units or $69,352,657 worth the previous month and 27,736 units at a value of $126,416,360 in December, 1942.

Unfilled backlogs of firm orders for December, 1943, were for 40,335 units, valued at $203,512,935 compared with 45,014 units totaling $237,395,828 in November and 148,345 units valued at $837,595,788 in December, 1942. Estimated backlog in January of 1944 is 36,000 machines valued at $174,000,000.

New pool orders in December were non-existent as compared with 13 units valued at $132,704 in November and 7831 units totaling $53,648,683 in December, 1942. No pool orders are reported for January. Unassigned pool orders representing 4810 units or about $38,100,889 worth in December, 1943, compare with 5596 units valued at $43,273,268 in November and 27,019 units totaling $195,421,248 in December of 1942.

Disposal of Government Tools

Cincinnati

• • • **The ultimate disposition** of government-owned machine tools is a very definite problem now engaging the attention of management in this area, as well as in other areas. In Cincinnati, of course, it is particularly important because a large portion of the local economy is dependent upon the machine tool industry and its associated lines. Some feeling seems to be fairly well crystallized that the Baruch report is a constructive document, but there are some parts which are open to question on the part of the manufacturers.

The effect of the government entering the market with a supply that has been estimated at about a billion dollars worth of machine tools, would just about clean out the machine tool industry, since this figure is considered to be four to five years' normal business for the industry. Even those who have been indicating that war being waste, machine tools that have been over-produced for the current conflict should, to some degree be stopped, are agreeing that there is probably a substantial portion of the government held machines that must necessarily find their way into the normal avenues of trade. They feel, however, that should these go into ordinary operation, the machine tool industry should have a share in the disposition of them, and a share in the profits to be made therefrom.

•

Used Tool Sales

Washington

• • • **Certificates of satisfactory** operation may be substituted in place of guarantees in sales of second-hand machine tools made on behalf of the government or where the government is the largest creditor, according to amendment No. 2 to MPR 1, effective Feb. 23. This written certificate substituted for the warranty must be signed by a qualified person not engaged in the business of selling second-hand tools and who is approved by the purchaser. The certificate must state that such person has inspected the machine tool, that all worn or missing parts have been replaced or reworked, and the second-hand machine tools have been tested under power so as to prove that it has a substantially equivalent performance to that of the machine when new.

• •

Machine and Parts Price Ceilings Revised Upwards

Washington

• • • **Two changes in** the regulation controlling the prices of machines and parts, and machinery services, were announced by OPA. The first defines "emergency" conditions under which persons subject to the regulation may pass on to buyers extraordinary expenses incurred for the purpose of expediting production and delivery. The second permits an increase in price of machines or parts containing domestic or Treasury silver by the amount of the increased cost of silver solder and babbitt metal since Aug. 10, 1943.

OPA formerly allowed the addition of extra charges incurred where an emergency required that materials be obtained from a source more expensive than the usual source or that a machine or part receive special handling after its manufacture. The revised action allows the addition of extra material costs resulting from manufacturers or machinery service suppliers purchasing materials in an emergency, at the request of the buyer, from a source more expensive than the current usual source. It also permits addition of extra transportation costs resulting from shipping such machines or parts or materials used in producing a machine or part, or supplying a machinery service by means more expensive than the usual shipping method.

Only actual extra costs of the material or transportation services may be added to the maximum price. These extra costs shall be billed to the buyer separately and a copy of the invoice forwarded immediately to the Machinery Branch of OPA.

Various types of machines and parts covered by the provisions of this maximum price regulation contain silver solder or babbitt metal containing silver.

We would really like to know the answer ourselves. The facts in the case are that Genesee today is one of the Nation's major producers of Dovetail tools just as it is among the leaders in the production of many other types of special tools.

It may have something to do with jealous maintenance of quality—though we know other companies make good tools too. It may have something to do with deliveries—though we haven't been too happy at times in the past when we looked at our banks of unfilled orders. Somehow "price" can't be the answer, for we have never sacrificed quality for the sake of price.

Perhaps it's just a combination of all of them. If you know, won't you tell us?

We welcome your comments and inquiries.

British Plan Extensive Program for Postwar Tin Technical Development

• • • **The British, in** planning for postwar production and distribution of its manufactured and raw materials, have more than a passing interest in the tin mining and smelting industry. Recently, John Ireland, director of the Tin Research Institute, described a plan involving the tin demands of postwar industrial and consumer markets. *Sheet Metal Industries*, a British trade publication, commented on the plan recently.

The plan shows that sales depend on the satisfaction of the ultimate consumer, and that where better service can be given expanded consumption follows.

The proposed scheme will harness to the problem of increasing the usefulness of tin, the full resources of a modern scientific organization. This will comprise a group of scientists whose work will be carried to the stage of practical application by research teams working on a semi-industrial scale under the guidance of committees representing each of the principal tin-consuming industries.

Information bureaus will be established in all the important tin-consuming centers throughout the world. These bureaus will be staffed by practical experts ready to go into works and put any tin-consuming process into first-class working order in the light of the most recent scientific knowledge. The experience gained in giving this type of service in Great Britain and on a smaller scale in the United States, has proved that there is a widespread need for it even in these areas where manufacturing technique is highly developed, and in other consuming countries there is even greater scope.

The report explains the proposed postwar organization in detail, and summarizes technical developments made in all the main fields of consumption. It gives the technical grounds on which are based the reasons for expecting to restore those uses of tin abandoned or curtailed during the present scarcity. The report also indicates some promising new uses arising out of the Institute's researches, and gives quantitative estimates of the increased sales that may be expected as the result of the new organization's activities at the end of a 10-year period.

The budget recommended for these activities is about $1¼ million per annum to cover research, development, world-wide technical service, and full supporting publicity. This sum, although much larger than that with which the present organization has been working, is much less than is devoted to other metals, and is only about one per cent of the gross value of the tin sold annually before the war.

•

Copper Scrap Pricing

• • • **Copper wire scrap** containing ashy, burnt, and dirty wire, with a copper content of 94 per cent should be priced at the maximum price of light copper rather than as No. 2 copper wire, according to a ruling issued by OPA. The maximum for No. 2 copper wire and mixed heavy copper, set at 8.75c. per lb., is subject to the requirement that the material must have a copper content of not less than 95 per cent. That specification applies to the scrap in the condition in which it is received by the consumer. The maximum price is not subject to any deduction for moisture, oil, grease, non-metallics, or other foreign materials, as are the prices for solids that are subject to Footnote No. 2 in the regulation.

The correct method of pricing copper wire with a copper content of 94 per cent is to price it at the maximum light copper price, where the copper content must be not less than 90 per cent. As such, it is entitled to the maximum base price of 7.75c. per lb., plus an addition of 0.11775c. per lb. for every 1 per cent above 92 per cent copper with proportionate adjustments for fractional variations.

•

New Copper Scrap Grade

• • • **Briquetted cartridge** brass turnings were provided with a 8.625c. per lb. ceiling, f.o.b. shipping point by the OPA. This price compares with a maximum price of 7.875c. per lb. for loose yellow brass turnings and for unbriquetted cartridge brass turnings. The new price for briquetted turnings is designed to offset costs incurred by the seller in briquetting the material, an operation normally performed by the buyers.

•

Lead Basing Point

• • • **Bayfield, Wis.,** was named a basing point for primary lead sales by OPA this past week because it has become a lead consuming center. The maximum price for lead, delivered at Bayfield in carload lots, is set at 6.50c. per lb. This is 0.10c. per lb. higher than other Wisconsin basing point to reflect higher freight costs.

•

Zinc Order Amended

• • • **Remelt zinc** was removed from allocation and scrap zinc deliveries are no longer controlled under amended order M-11. Also, the procedure in applying for and receiving authorizations to accept delivery of slab zinc has been altered to reduce paper work and simplify it. The order no longer requires dealers to obtain an AA-5 rating or better before making shipments. Remelt and scrap zinc changes are effective April 1, following filing of the new applications on March 12. The amended order also permits producers to make shipments upon notification from a purchaser of the date and serial number of his authorization certificate.

•

New Navy Plant

Pittsburgh

• • • **A new aluminum plant** to produce atomized aluminum is under construction at Glassmere, Pa., according to an announcement this week by the Navy. The plant, which is being built on a 32-acre tract purchased from the Ford Motor Co., will be operated by the Aluminum Co. of America under an agreement with the Navy.

The site was chosen because of its proximity to the Logan's Ferry plant of Aluminum Co., where atomized aluminum has been produced for some time.

Rail Scrap Price System Accepted Favorably by Trade

• • • **While the revised** railroad iron and steel scrap price schedule has not been in effect long enough to test its workability, there seems to be no doubt but that the schedule will be quite satisfactory both from a consumer and a scrap producer standpoint. There is one phase of the schedule that has caused some disturbance, however, and that is the fact that railroad scrap producers not on a basing point are not getting the price for their material that they received heretofore.

These producers, selling under the new basing point system, must absorb freight costs from the accumulation point to the nearest basing point, which was not so under the old schedule. Previously, producers not on a basing point had set prices, determined by average sales over a base period, to which were added freight charges. This was a neat setup for as long as it lasted, because frequently mills that had railroad scrap allocated to them by WPB found they were paying far more than would be paid for identical scrap from roads running through their mills.

Also, stricter grading of rail scrap under the new system that actually specifies what constitutes a given grade has cut into scrap proceeds of producers. Loose grading was more prevalent under the old system, but under the new plan the grade classifications are quite specific as to what is included.

The weakness in the low phos market during the past several months continues, with dealers in the east offering at $1 below the ceiling. However, because of the tightening up of this classification in Amendment 14 to RPS 4, where punchings, plate scrap, and bar crops minimum dimensions were raised and much of what formerly went as low phos now is listed as No. 1 bushelings, some authorities expect this low phos surplus to disappear and the demand become considerably stronger. The surplus of low phos has obviously been the result of consolidation of other grades into this classification to earn the grade premium. The cream of open hearth grades could well be worked into this classification. Better quality will bring better prices and stronger demand, and stricter measures may be adopted to keep open hearth heavy melting grades in their proper classes.

•

PITTSBURGH—Heavy melting grades are in strong demand, but despite poor collections of dealers scrap no serious shortages have resulted. Some tonnages of short shoveling turnings have come into the district from distant points without the springboard, suggesting weakness at the source. Prices for this material here are at the ceilings, the local market showing no weakness. The Bureau of Mines suggestion that an acute situation will arise before the winter is out has met with mixed reactions here. Some sources believe the authority of the government to more forcibly use allocations and the fact that the Army could be used as a last resort, precludes any acute or serious shortage of scrap in the near future.

•

BIRMINGHAM—Foundries in this district have limited freight charges to $3 per gross ton on cast grades, and on blast furnace grades some mills will only accept material at a price not to exceed $1 springboard although the district is allowed a $2 springboard. Trade sources here assert that while purchasers in the above instances are not absorbing the full freight charges, no scrap at present is being sold below ceiling in this area.

Going Scrap Prices

• • • Reports of under-ceiling sales for various grades of scrap specified were made in the following cities:

Buffalo—Alloys and stainless grades sold with alloy premiums waived.

Boston—Nickel turnings and solids find no markets. Would sell with premiums waived.

St. Louis—Machine shop turnings sales at $2 below ceiling.

New York—Low phos offered $1 below ceiling.

Cleveland — Short shoveling turnings being included in machine shop turnings shipments.

Cleveland—Nickel alloy solids and turnings sales without premium.

Cleveland—Blast furnace turnings sales out of area at $1 below ceiling.

Los Angeles—Open hearth grades sales at $2 under ceiling not in any manner indicative of general conditions as this is surplus scrap area.

LOS ANGELES — Basic open hearth and blast furnace grades move at $2.00 below ceiling or less. Low phos and electric furnace plate scrap principally from shipyards hold ceiling prices, but movement is sluggish and demand light. Steel turnings and borings are being compressed and crudely amalgamated as ship ballast on a fairly extensive scale for cargo vessels converted to troop carriers and naval auxiliaries. The demand for sheared, detinned, and baled cans is so light either for copper precipitation or melting grade that tin can collections may be discontinued. Present below ceiling prices will not cover collection and shipping charges to detinning plants.

•

BUFFALO—Easing of the scrap situation in the Buffalo district is noted with the arrival of more shipments outside territories, including Canada. Despite improved weather, yard men reported operations remained slow.

•

CINCINNATI — Dealers here indicate that current purchases still hold at ceiling prices and so far no reduction under the ceiling is reported except for isolated instances of refusal on the part of purchasers to pay "spring board" differentials. Machine shop turnings are plentiful and difficulty is experienced in disposing of them, but good scrap is at a minimum. Scrap consumers generally, however, are apparently receiving sufficient material to keep them operating and the pressure is not great.

•

CHICAGO — Weakness is evident in sales of short shoveling turnings from $1.50 to $2.00 below ceiling, probably occasioned by withdrawal of a major purchaser. Basic open hearth grades remain stable, however. Electric furnace material is moving slowly without premiums and what few sales of alloy grades are being made continue at no premium over carbon grades.

•

BOSTON—No improvement in the supply or shipment of scrap is reported by the average yard and some brokers maintain the past week was their quietest on record. As weeks progress without any stepup in supply, general opinion that a real pinch in the situation lies ahead gains ground. To substantiate reports from yards and brokers, railroads say shipments are now running less than 50 per cent of a year ago.

•

ST. LOUIS—Sheffield Steel Corp., whose St. Louis plant has been operating only two of its six open hearth furnaces for some time, has taken these off because of cut backs and the resulting lack of business. There still is a shortage of heavy melting steel, with supplies sufficient only for the next 30 days' operations. A late heavy snow Feb. 28 will further slow up shipments from the country and handling of scrap here.

* Baled turnings are $5 per gross ton higher.

BUNDLES: Tin can bundles are $4 below dealers' No. 2 bundles; No. 3 bundles are $2 less than No. 1 heavy melting.

AT NEW YORK CITY or Brooklyn, the maximum shipping point price is $15.33 for No. 1 heavy melting, f.o.b. cars, f.a.s. vessel or loaded on truck. Minimum set at $14 per gross ton at any shipping point in U. S. Other grades carry differentials similar to those in table. New Jersey prices must be computed on basis of all-rail. At Boston the maximum is $15.05 for No. 1 f.o.b. cars, f.a.s. vessel or loaded on trucks. Shipments from a New England shipping point to a consumer outside New England carry maximum transportation charge of $6.66 per ton.

SWITCHING CHARGES: Deductions for shipping points within basing point (cents per gross ton) are: Chicago, 84c.; Pittsburgh, Brackenridge, 55c.; Detroit, 53c.; Midland, Johnstown, Sharon, Youngstown, Warren, Weirton, Cleveland, Toledo, Los Angeles, San Francisco, Pittsburg, 42c.; Seattle, 38c.; Buffalo, Claymont, Harrisburg, 36c.; Atlanta, Birmingham, 32c.; Butler, Monessen, Canton, Steubenville, Cincinnati*, Portsmouth, Ashland, Coatesville, Phoenixville, Bethlehem, Kokomo, Duluth and St. Louis, 28c.; Alabama City, Ala., 26c.; Minnequa, Colo., 22c.; Middletown, 14c.; Conshohocken, Sparrows Point, 11c.

*Basic open hearth and foundry grades, and auto springs and crankshafts, deduct 80c. per ton.

BASING POINT includes switching districts of city named.

Basing point	Switching districts:
Pittsburgh	Bessemer, Homestead, Duquesne, Munhall, McKeesport
Cincinnati	Newport
St. Louis	Granite City, E. St. Louis, Madison, Ill.
Chicago	Gary
Claymont	Chester, Pa.
San Francisco	So. San Francisco, Niles, Oakland

MAXIMUM SHIPPING POINT PRICE: Where shipment is wholly or partially by rail or vessel, or combination of rail and vessel, the scrap is at shipping point when placed f.o.b. railroad or f.a.s. vessel. For motor vehicle shipments scrap is at shipping point when loaded. Then maximum shipping point price shall be: (a) For shipping point located within a basing point, prices shown in above table for scrap at basing point in which shipping point is located, minus applicable switching charge deduction shown in paragraph above labeled "Switching Charges." (b) For shipping points outside basing point, price listed in above table hereof for scrap at most favorable basing point, minus lowest charge for transportation from shipping point to such basing point by rail or water carrier or combination. Where vessel movement is involved, in lieu of established dock charge or any cost customarily incurred at the dock, 75c. per ton must be included as part of deduction in computing shipping point price; 50c. at Memphis; $1 at Great Lakes ports; and $1.25 at New England ports. If no established transportation rate exists for a portion of movement from shipping to basing point, actual charge or cost customarily incurred by shipper in such portion of movement shall be included as part of deduction in computing shipping point price. For exceptions see official order.

UNPREPARED SCRAP: For unprepared scrap, maximum prices shall be $3.50 (and in the case of the material from which No. 1, No. 2, and No. 3 bundles are made $4) less maximum prices for the corresponding prepared scrap. In no case, however, shall electric furnace, acid open hearth and foundry grades be used as the corresponding prepared scrap. A preparation-in-transit charge for unprepared scrap is provided.

NEW LISTED GRADES: Priced in dollars per gross ton less than No. 1 heavy melting steel. Pit scrap, ladle skulls, slag reclaim, etc., of 85% or more Fe priced less $2; 75 to 85% Fe less $4; under 75% Fe less $8 per ton. Mill scale less $8 per ton. Mill cinder and grindings, shipping point maximum price of $4 per gross ton at all U. S. shipping points.

CHEMICAL BORINGS: No. 1 (new, clean, containing not more than 1% oil), $1 less than No. 1 heavy melting; No. 2 (new, clean, containing not more than 1.5% oil), $2 less than No. 1 heavy melting. If loaded in box cars add 75c. mill scale, $8 less than No. 1 heavy melting.

Tool Steel Scrap Prices (MPR 379)

	SEGREGATED			UNSEGREGATED SOLIDS	UNSEGREGATED TURNINGS
		Solids Per Lb. Cont. W	Turnings Per Lb. Cont. W		
Type 1.	12% min. W, 1% max. Mo	$1.80	$1.60	$1.50 per lb. contained W if 5% or more.	$1.30 per lb. contained W if 5% or more.
Type 2.	5 to 12% W, 1% max. Mo	1.60	1.40	$1.15 per lb. contained W if 1 to 5%.	$1.00 per lb. contained W if 1 to 5%.
Type 3.	1 to 5% W, 1.5% max. Mo	1.25	1.25	$0.80 per lb. contained Mo if 1.5% or more.	$0.70 per lb. contained Mo if 1.5% or more.
*Type 4.	7% min. Mo, 2% max. W	0.125	0.105	If both W and Mo are within ranges, payment may be for both W and Mo content.	
*Type 5.	3.5 to 6% Mo, 4.5 to 6% W	0.135	0.115		

*Per lb. of scrap material.
If segregated, a premium of $1.50 per lb. of contained Co allowed if Co content is 3% or over. No scrap considered segregated if Co content ranges between 0.5 and 3%.
If Cu or Ni content over 0.25%, price shall be reduced by 50%.
If 500 lb. or less is sold, either segregated or unsegregated, price shall be reduced 2c. per lb. of scrap material.

Revised price schedules, establishing dollars and cents differentials for railroad scrap and establishing revisions in cast iron scrap grades are shown on page 158. These schedules, amendment 14 to RPS No. 4, replace the previous schedules on Railroad Steel Scrap and Cast Iron Scrap sold by railroads.

Comparison of Prices . . .

The various basing points for finished and semi-finished steel are listed in the detailed price tables, pages 136-151.

Composite Prices . . .

Starting with the issue of April 22, 1943, the weighted finished steel price index was revised for the years 1941, 1942 and 1943. See explanation of the change on page 90 of the April 22, 1943, issue.

	FINISHED STEEL	PIG IRON	SCRAP STEEL

Weighted index based on steel bars, beams, tank plates, wire, rails, black pipe, hot and cold-rolled sheets and strip, representing 78 per cent of the United States output. Index recapitulated in Aug. 28, 1941, issue.

Based on averages for basic iron at Valley furnaces and foundry iron at Chicago, Philadelphia, Buffalo, Valley and Southern iron at Cincinnati.

Based on No. 1 heavy melting steel scrap quotations to consumers at Pittsburgh, Philadelphia and Chicago.

. . . Prices of Finished Iron and Steel

Steel prices shown here are f.o.b. basing points, in cents per lb., unless otherwise indicated. Extras apply. Delivered prices do not reflect 3% tax on freight. (1) Mill run sheet, 10c. per 100 lb. under base; primes 25c. above base. (2) Unassorted 8-lb. coating. (3) Widths up to 12-in. (4) 0.25 carbon and less. (5) Applies to certain width and length limitations. (6) For merchant trade. (7) For straight length material only from producer to consumer. Discount of 25c. per 100 lb. to fabricators. (8) Also shafting. For quantities of 20,000 to 29,999 lb. (9) Carload lot in manufacturing trade. (10) Prices do not apply if rail and water is used. (12) Boxed. (13) Portland and Seattle price, San Francisco 2.50c. (14) This base price to be used in figuring annealed, bright finish wires, commercial spring wire.

Steel Sheet Piling	2.40¢	2.40¢				2.40¢						2.95¢			2.72¢

EXCEPTIONS TO PRICE SCHED. NO. 6

Slabs—Andrews Steel Co. $41 basing pts.; Wheeling Steel Corp. $34 Portsmouth, Ohio; Empire Sheet & Tin Plate Corp. $41; Phoenix Iron Co. (rerolling) $41, (forging) $47; Granite City Steel Co. $47.50.

Blooms—Phoenix Iron Co. (rerolling) $41, (forging) $47.

Sheet Bar—Empire Sheet & Tin Plate Co. $39 mill; Wheeling Steel Corp. $38 Portsmouth, Ohio.

Billets, Forging—Andrews Steel Co. $50 basing pts.; Follansbee Steel Corp. $49.50 Toronto; Phoenix Iron Co. $47.00 mill.

Billets, Rerolling—Continental Steel Corp. may charge Acme Steel in Chicago switching area $34 plus freight from Kokomo, Ind.; Northwestern Steel & Wire Co. (Lend-Lease) $41 mill; Wheeling Steel Corp. (small) $36 Portsmouth, Ohio; (blooming mill sizes) applicable base, f.o.b. Portsmouth, Ohio; Stanley Works may sell Washburn Wire Co. under allocation at $39 Bridgeport, Conn.; Keystone Steel & Wire Co. may sell Acme Steel Co. at Chicago base, f.o.b. Peoria; Phoenix Iron Co. $41 mill; Continental Steel Corp. (1¾ x 1¾) $39.50, (2 x 2) $40.60 Kokomo, Ind. (these prices include $1 size extra); Keystone Steel & Wire Co. $36.40 Peoria; Connors Steel Co. $50.69 Birmingham; Ford Motor Co. $34 Dearborn, Mich.

Structural Shapes—Phoenix Iron Co. $2.35 basing pts., (export) $2.50 Phoenixville; Knoxville Iron Co. $2.30 basing pts.; Sheffield Steel Corp. $2.55 St. Louis.

Bar Size Shapes—(Angles) W. Ames & Co., 10 tons or over, $3.10 mill.

Rails—Sweet Steel Co. (rail steel) $50 mill; West Virginia Rail Co. (lightweight) on allocation based Huntington, W. Va.; Colorado Fuel & Iron Corp. $45 Pueblo.

Hot Rolled Plate—Granite City Steel Co. $2.65 mill; Knoxville Iron Co. $2.25 basing pts.; Kaiser Co. $3.20 Pacific Ports.

Merchant Bars—Sheffield Steel Corp. $2.75 St. Louis; W. Ames & Co., 10 tons and over, $2.85 mill; Eckels-Nye Steel Corp., $2.50 basing pts. (rail steel) $2.40; Phoenix Iron Co. $2.40 basing pts.; Sweet Steel Co. (rail steel) $2.35 mill; Joslyn Mfg. & Supply Co. $2.35 Chicago; Central Iron & Steel Co. $2.20 basing pts.; Granite City Steel Co. $2.35 Granite City; Calumet Steel Div., Borg Warner Corp. (8 in. mill bars) $2.35 Chicago; Knoxville Iron Co. $2.30 basing pts. Laclede Steel Co., sales to LaSalle Steel granted Chicago base, f.o.b. Madison, Ill.

Reinforcing Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Sweet Steel Co. (rail steel) $2.35 mill; Columbia Steel Co. $2.50 Pacific Ports.

Cold Finished Bars—Keystone Drawn Steel Co. on allocation, Pittsburgh c.f. base plus c/l freight on hot rolled bars Pittsburgh to Spring City, Pa.; New England Drawn Steel Co. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to Massfield. Mass.. f.o.b. Massfield.; Empire Finished Steel Corp. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to plants f.o.b. plant; Compressed Steel Shafting Co. on allocation outside New England, Buffalo base plus c/l freight Buffalo to Readville, Mass. f.o.b. Readville; Medart Co. in certain areas, Chicago c.f. base plus c/l freight Chicago to St. Louis, f.o.b. St. Louis.

Alloy Bars—Texas Steel Co. for delivery except Texas and Okla. Chicago base, f.o.b. Fort Worth, Tex.; Connors Steel Co. shipped outside Ala., Mississippi, Louisiana, Georgia, Florida, Tenn., Pittsburgh base, f.o.b. Birmingham.

Hot Rolled Strip—Joslyn Mfg. & Supply Co. $2.30 Chicago; Knoxville Iron Co. $2.25 basing pts.

Hot Rolled Sheets—Andrews Steel Co., Middletown base on shipments to Detroit or area; Parkersburg Iron & Steel Co., $2.25 Parkersburg.

Galvanized Sheets—Andrews Steel Co., $3.75 basing pts.; Parkersburg Iron & Steel Co. $3.85 Parkersburg; Apollo Steel Co. $3.75 basing pts.; Continental Steel Co., Middletown base on Kokomo, Ind., product; Superior Sheet Steel Co., Pittsburgh base except for Lend-Lease.

Pipe and Tubing—South Chester Tube Co. when priced at Pittsburgh, freight to Gulf Coast and Pacific Ports may be charged from Chester, Pa., also to points lying west of Harrisburg, Pa.

Black Sheets—Empire Sheet and Tinplate Co., maximum base price mill is $2.45 per 100 lb., with differentials, transportation charges, etc., provided in RPS. No. 6.

WAREHOUSE PRICES

Delivered metropolitan areas per 100 lb. These are zoned warehouse prices in conformance with latest zoning amendments to OPA Price Schedule 49.

*Recommended for large sections only. Note: The extras shown are in addition to a base price of 2.70c. per 100 lb., on finished products and $54 per gross ton on semi-finished steel major basing points and are in cents per 100 lb. and dollars per gross ton in semi-finished. When acid open-hearth is specified and acceptable add to basic open hearth alloy differential 0.25c. per lb. for bars and bar strip, $5.00 per gross ton for billets, blooms and slabs. The ranges shown above are restricted to sizes 100 sq. in. or less or equivalent cross sectional area 18 in. wide or under with a max. individual piece weight of 7000 lb.

BASE QUANTITIES

Standard unless otherwise keyed on prices.

HOT ROLLED: Sheets, strip, plates, shapes and bars, 400 to 1999 lb.

COLD ROLLED: Sheets, 400 to 1999 lb.; strip, extras on all quantities; bars, 1500 to 39,999 lb.; NE alloy bars, 1000 to 39,999 lb.

EXCEPTIONS: (1) 150 to 499 lb. (2) 150 to 1499 lb. (3) 400 to 1499 lb. (4) 450 to 1499 lb. (5) 500 to 1499 lb. (6) 0 to 1999 lb. (7) 400 to 1999 lb. (8) 1000 to 1999 lb. (9) 450 to 3749 lb. (10) 400 to 3999 lb. (11) 300 to 4999 lb. (12) 300 to 10,000 lb. (13) 400 to 14,999 lb. (14) 400 to 39,999 lb. (15) 1000 to 39,999 lb. (16) 1500 to 39,999 lb. (17) 2000 to 39,999 lb. (18) 3500 to 39,999 lb.

(a) Philadelphia: Galvanized sheets, 25 or more bundles.

Extra for size, quality, etc., apply on above quotations.

CAST IRON WATER PIPE

	Per Net Ton
6-in. and larger, del'd Chicago	$54.80
6-in. and larger, del'd New York	52.20
6-in. and larger, Birmingham	46.00
6-in. and larger f.o.b. cars, San Francisco or Los Angeles	69.40
6-in. and larger f.o.b. cars, Seattle.	71.20

Class "A" and gas pipe, $3 extra; 4-in. pipe is $3 a ton above 6-in. Prices shown are for lots of less than 200 tons. For 200 tons or over, 6-in. and larger is $45 at Birmingham and $53.80 delivered Chicago, $59.40 at San Francisco and Los Angeles, and $70.20 at Seattle. Delivered prices do not reflect new 3 per cent tax on freight rates.

LAKE SUPERIOR ORES

(51.50% Fe, Natural Content, Delivered Lower Lake Ports)*

	Per Gross Ton
Old range, bessemer, 51.50	$4.75
Old range, non-bessemer, 51.50	4.60
Mesaba, bessemer, 51.50	4.60
Mesaba, non-bessemer, 51.50	4.45
High phosphorus, 51.50	4.35

*Adjustments are made to indicate prices based on variance of Fe content of ores as analyzed on a dry basis by independent laboratories.

SEMI-FINISHED STEEL

Ingots, Carbon, Rerolling

Base per gross ton, f.o.b. mill.... $31.00

Exceptions: Phoenix Iron Co. may charge $38.75; Kaiser Co., $43.00 f.o.b. Pacific Coast Ports; Empire Sheet & Tinplate Co., $34.25.

Ingots, Carbon, Forging

Base per gross ton, f.o.b. Birmingham, Buffalo, Chicago, Cleveland, Gary, Pittsburgh, Youngstown $36.00

Exceptions: Phoenix Iron Co. may charge $43.00; Empire Sheet & Tinplate Co., $39.25, f.o.b. Mansfield, Ohio; West Coast producers, $48.00, f.o.b. Pacific Coast Ports.

Ingots, Alloy

Base per gross ton, f.o.b. Bethlehem, Buffalo, Canton, Coatesville, Chicago, Massillon, Pittsburgh $45.00

Exceptions: C/L delivered Detroit add $2.00; delivered East Michigan add $3.00. Connors Steel Co. may charge $45.00 f.o.b. Birmingham.

Billets, Blooms and Slabs

Pittsburgh, Chicago, Gary, Cleveland, Youngstown, Buffalo, Birmingham, Sparrows Point (rerolling only). Prices delivered Detroit are $2.00 higher; delivered E. Michigan, $3 higher; f.o.b. Duluth, billets only, $2.00 higher; billets f.o.b. Pacific ports are $12 higher. Delivered prices do not reflect three per cent tax on freight rates.

	Per Gross Ton
Rerolling	$34.00
Forging quality	40.00

For exceptions on semi-finished steel see the footnote on the page of finished steel prices.

Alloy Billets, Blooms, Slabs

Pittsburgh, Chicago, Canton, Massillon, Buffalo, or Bethlehem, per gross ton 54.00

Price delivered Detroit $2.00 higher; E. Michigan $3.00 higher.

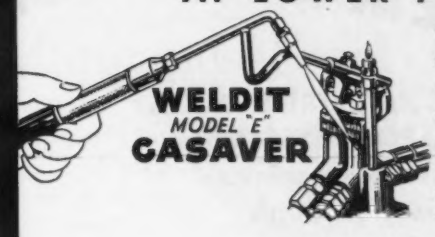
Shell Steel

	Per Gross Ton
3 in. to 12 in.	$52.00
12 in. to 18 in.	54.00
18 in. and over	56.00

Basic open hearth shell steel, f.o.b. Pittsburgh, Chicago, Buffalo, Gary, Cleve-

Safe Welding

AT LOWER PRODUCTION COSTS



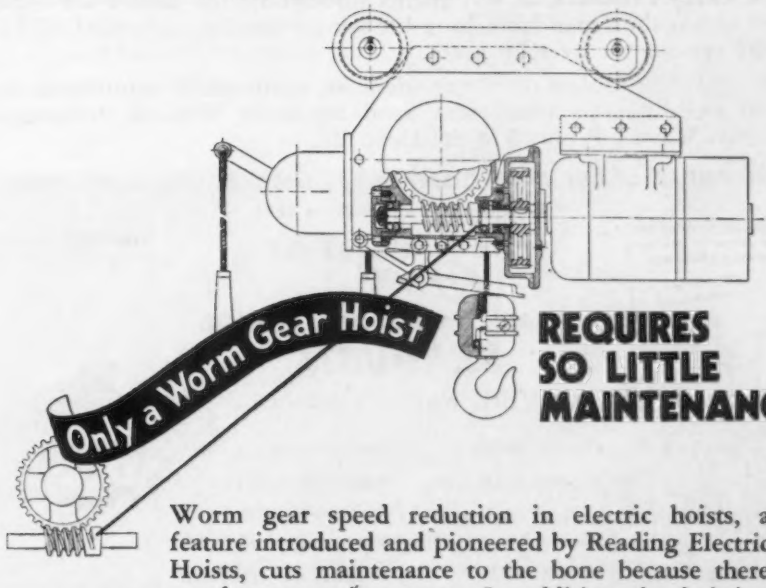
The Weldit Gasaver shuts off the welding flame when not in use. . . . Conserves essential materials by cutting oxygen and acetylene consumption as much as *fifty* per cent. Prevents injury to workmen—or sudden fires—from dangerous idle torch flames. . . . Adjustment remains unaltered between welds.

When the Weldit Gasaver has been installed, you simply hang idle torch on the handy lever rod. Weight of torch pulls rod down, thus automatically shutting off supply lines. Relight instantly by passing torch over Gasaver pilot light. No bother. . . . No time lost. . . . *No readjusting required.* . . . Price $10.00 at Detroit. Order today.

Better Soldering, Annealing and Heating Jobs

The Weldit Model CW Blowpipe is in daily use by many foremost industrial plants. . . . Built in accordance with the recommendations of leading fabricators of sheet metal products. . . . Operates on either natural gas, manufactured gas, or other low temperature fuel gas and compressed air. Stands up under rough shop use. . . . Send for literature.

WELDIT ACETYLENE CO.
641 BAGLEY AVENUE • DETROIT 26, MICH.



REQUIRES SO LITTLE MAINTENANCE

Worm gear speed reduction in electric hoists, a feature introduced and pioneered by Reading Electric Hoists, cuts maintenance to the bone because there are fewer wearing parts. In addition the hoisting unit proper is compact and very simple with only four moving parts. The unit construction of Reading Hoists makes all parts easily accessible for inspection and maintenance by the average mechanic.

It will pay you to investigate the money-saving features of Reading Electric Hoists. For full technical information write for Bulletin 1004.

Carey PRODUCTS KEEP 'EM WORKING!

WAR PLANTS • OIL REFINERIES • MILLS • MINES • TRANSPORT SYSTEMS • POWER PLANTS • *Achieve Peak Efficiency Through Proper Maintenance of Buildings and Equipment*

Industrial management well recognizes the need for proper maintenance of plants and equipment, in order to insure a continuous flow of vital war production.

But with many key men in the armed forces, managers, engineers and executives do not always have the time or help to check and re-check the multitudinous details involved.

Right here, CAREY is performing a vital role. Our nationwide engineering and distribution organization is working hand in hand with plant managers and engineers throughout the country—checking plants and helping to solve problems of efficient, economical repair and maintenance.

And Carey Products, in war plants throughout the nation are right now giving the dependable, long-life service that has made the CAREY name famous for over 70 years.

If you have a problem involving adequate, economical maintenance of plant buildings or equipment, send for book "Proved Protection Against Wasted Profits." Write Dept. 26.

THE PHILIP CAREY MFG. COMPANY, Lockland, Cincinnati, Ohio

Dependable Products Since 1873

Careyduct Air Conveying Systems conserve metals and increase efficiency.

Over 1900 Liberty Ship engines are Carey insulated.

PARTIAL LIST OF Carey ASPHALT-ASBESTOS-MAGNESIA **PRODUCTS** IN THE NATION'S SERVICE

BUILT-UP ROOFS — ROOF COATINGS
AIR-CONVEYING DUCT — INDUSTRIAL FLOORING
WALL BOARD AND SHEATHING — EXPANSION JOINTS
HEAT INSULATIONS
PIPELINE FELT — ASBESTOS OIL ABSORBENT
CORRUGATED ASBESTOS-CEMENT ROOFING & SIDING

Heat Insulation saves fuel in power plants.

Built-Up Roofs provide weather protection.

Asbestos Pipeline Felt protects "Big Inch" oil line against corrosion.

PRICES

land, Youngstown and Birmingham.
Prices delivered Detroit are $2.00 higher; E. Michigan, $3 higher.

Note: The above base prices apply on lots of 1000 tons of a size and section to which are to be added extras for chemical requirements, cutting, or quantity.

Sheet Bars

Pittsburgh, Chicago, Cleveland, Youngstown, Buffalo, Canton, Sparrows Point.

	Per Gross Ton
Open hearth or bessemer	$34.00

Skelp

Pittsburgh, Chicago, Youngstown, Coatesville, Pa., Sparrows Point, Md.

	Per Lb.
Grooved, universal and sheared	1.90c.

½ in.	25	6
¾ in.	31	12
1 to 2 in.	38	19½
Steel (Lap, extra strong, plain ends)		
2 in.	59	48½
2½ and 3 in.	63	52½
3½ to 6 in.	66½	56
Wrought Iron (Same as Above)		
2 in.	33½	15½
2½ to 4 in.	39	22½
4½ to 6 in.	37½	21

On butt weld and lap weld steel pipe jobbers are granted a discount of 5%. On less-than-carload shipments prices are determined by adding 25 and 30% and the carload freight rate to the base card.

F.o.b. Gary prices are two points lower discount or $4 a ton higher than Pittsburgh or Lorain on lap weld and one point lower discount, or $2 a ton higher on all butt weld.

In the Production of Magnesium, Both Amsco Alloy and Amsco Manganese Steel Have Found a Place

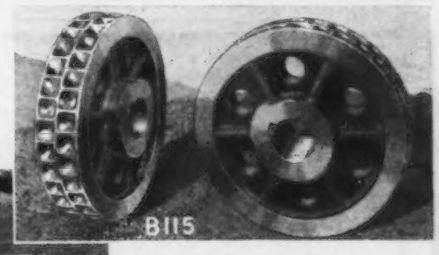
Multiplying by many times America's output of magnesium to meet such needs as lightweight aircraft parts and incendiary bombs has been one of industry's major accomplishments.

In the Pidgeon process of magnesium production, both Amsco Alloy and Amsco Manganese Steel are used in applications where their respective properties help make continuous operation possible. This process consists of distilling metallic magnesium in the form of vapor from briquettes made of a mixture of ferro-silicon and dolomite under low pressure in a furnace, operating at a temperature of about 2150° F.

There are usually twenty retorts to each furnace, laid side by side. After gases (principally hydrogen) have passed off, the retort is sealed and a vacuum, as nearly perfect as possible, is produced. The retort castings must, therefore, be leakproof. The vapor is condensed by a water jacketed condenser sleeve inserted prior to sealing in the open end of the retort, crystals forming in a dense mass in the sleeve. These crystals, averaging about 15 lbs. per retort at the end of an 8-hour run, are melted and cast into pigs.

Picture R-864 shows some of the Amsco Alloy retorts employed, and in picture K-26 appears one of the many carloads of these retorts which have been shipped during the past two years to producers of magnesium by the Pidgeon process.

Amsco manganese steel also has a part in the same process, in the form of the pressure rolls shown in picture B-115, used for forming the briquettes of powdered ferro-silicon and dolomite. Here the high resistance of manganese steel to pressure loads and abrasive wear affords maximum service life.



Bulletin 108 describes the uses of Amsco Alloy in all industry; and 1041A deals specifically with heat-treating containers.

Send for Bulletin 941W on Amsco Conservation Welding Rods.

GRAY FORGE IRON: Valley or Pittsburgh furnace $23.50

(1) Pittsburgh Coke & Iron Co. (Sharpsville, Pa., furnace only) and the Struthers Iron and Steel Co., Struthers, Ohio, may charge 50c. a ton in excess of basing point prices for No. 2 foundry, basic, bessemer and malleable.

(2) Price shown is for low-phosphorous iron; high-phosphorous sells for $28.50 at the furnace.

(3) E. & G. Brooke Co. permitted to charge $1.00 per ton extra.

(4) Pittsburgh Ferromanganese Co. (Chester furnace only) may charge $2.25 a ton over maximum basing point prices.

Basing point prices are subject to switching charges; silicon differentials (not to exceed 50c. a ton for each 0.25 per cent silicon content in excess of base grade which is 1.75 per cent to 2.25 per cent); phosphorous differentials, a reduction of 38c. per ton for phosphorous content of 0.70 per cent and over; manganese differentials, a charge not to exceed 50c. per ton for each 0.50 per cent manganese content in excess of 1.00 per cent. Effective March 3, 1943, $2 per ton extra may be charged for 0.5 to 0.75 per cent nickel content and $1 per ton extra for each additional 0.25 per cent nickel.

METAL POWDERS

Prices are based on current market prices of ingots plus a fixed figure. For ton lots f.o.b. shipping point, in cents per lb.

Copper, electrolytic, 150 and 200 mesh ..... 21⅛ to 23⅛c.

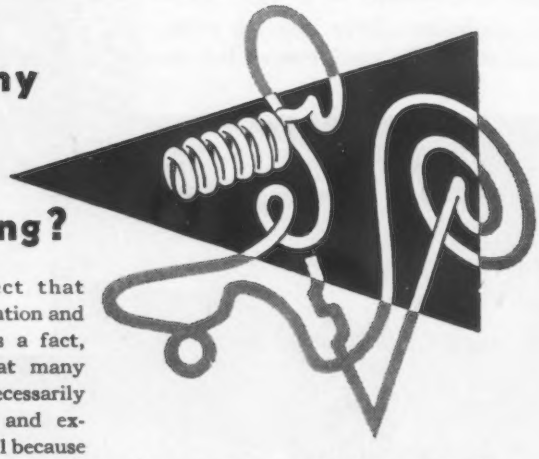
How many BENDS in a Spring?



Here's a subject that deserves close attention and investigation. It's a fact, sad but true, that many springs are unnecessarily intricate, difficult and expensive to make, all because of lack of understanding of the ultimate purpose. Ofttimes, a simplified design—or a different type of material can do wonders in the way of reducing costs and "upping" performance. Here's where experience in spring design pays off. Let the springmaker in on your requirements—in the early stages if possible.

A good spring in time saves nine!

GET AN ANALYSIS OF YOUR CUTTING JOBS

—without obligation

Based on the actual production records of the CAMPBELL complete range—the only complete range—of Abrasive Cutting Machines, Campbell engineers will gladly work up cost sheets and production procedures for your cutting. • All you need do is state the materials, shapes and sizes you are cutting, lengths before cutting, lengths of cut-off pieces and production required per hour. • The schedules given you will be practical and attainable. They will be based on the performance of some one of the 8 types and 19 models of CAMPBELL Abrasive Cutting Machines that are currently cutting all grades of steel, annealed and unannealed, non-ferrous alloys, plastics, glass and ceramics—solid bars, tubular and flat stock. • Ask for a copy of the chart shown above, too. It will give you fundamental information on the possibilities of abrasive cutting—at a glance.

Campbell Cutamatic No. 401
Oscillating and Rotating Wheel. Cuts steel up to 6".

Campbell No. 302
Odd shapes, Flat Stock, Slotting Flat Stock, etc.

Campbell No. 213
Cuts Tubing up to and including 3½". Solids to 2".

Campbell Cutalator No. 425
Cuts Tubing up to and including 4½". Solid Bar to 3½".

PERFORATED METALS

★

Any Metal

Any Perforation

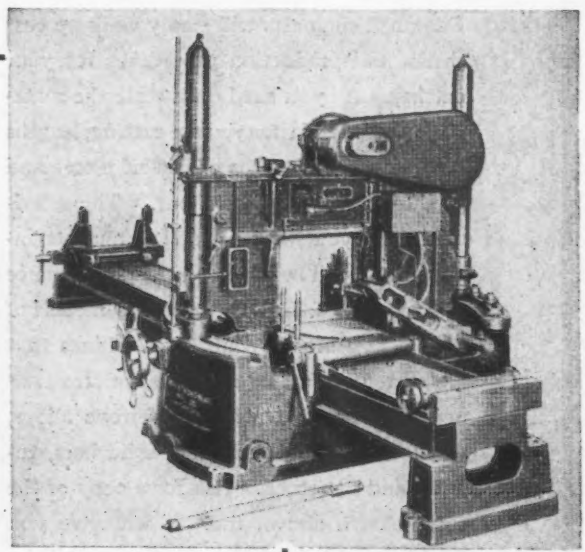
For **INDUSTRIAL** purposes a great variety of sizes and shapes of perforations are required, ranging from very fine to as large as 6" or more in diameter. We are equipped to supply all standard perforations in all kinds and thicknesses of metals.

ORNAMENTAL patterns are covered by our grille catalog. If interested, we hope you will send for it. There are attractive patterns for different uses.

The Harrington & King Perforating Co.

5667 FILLMORE ST., CHICAGO 44 • EASTERN OFFICE: 114 LIBERTY ST., NEW YORK 6, N. Y.

CUTS the Toughest Steels and Largest Sizes *easily.*



This giant hydraulic metal - cutting saw is more than just a larger hack saw. It is a new development in metal-cutting methods that introduces a new principle of metal sawing — the Roll-stroke blade action makes it possible to cut the toughest steels in the largest sizes easily and rapidly. It also permits a simple and efficient, very low pressure Hydraulic Feed System.

Built for heavy work completely enclosed in heavy housing, this machine will stand up under the rough usage of the average steel mill warehouse and forge shop, where it will speed cutting-off and reduce material loss.

MARVEL No. 18
Giant Hydraulic Hack Saw
Capacity 18"x18"

Cuts angles up to 45° by simply swiveling upper machine housing.

PRICES

Ferromanganese

78-82% Mn, maximum contract base price per gross ton, lump size, f.o.b. car at Baltimore, Bethlehem, Philadelphia, New York, Birmingham, Rockdale, Rockwood, Tenn.

Carload lots (bulk)	$135.00
Carload lots (packed)	141.00
Less ton lots (packed)	148.50

Premium, $1.70 for each 1% above 82% Mn; penalty, $1.70 for each 1% below 78%.

Manganese Metal

Contract basis, lump size, per lb of metal, f.o.b. shipping point with freight allowed. Spot sales add 2c. per lb.

96-98% Mn, .2% max. C, 1% max. Si, 2% max. Fe.

Carload, bulk	36c.
L.c.l. lots	38c.

95-97% Mn, .2% max. C, 1.5% max. Si, 2.5% max. Fe.

Carload, bulk	34c.
L.c.l. lots	35c.

Spiegeleisen

Maximum base, contract prices, per gross ton, lump, f.o.b. Palmerton, Pa.

	16-19% Mn 3% max. Si	19-21% Mn 3% max. Si
Carloads	$35.00	$36.00
Less ton	47.50	48.50

Electric Ferrosilicon

OPA maximum base price cents per lb. contained Si, lump size in carlots, f.o.b. shipping point with freight allowed to destination.

	Eastern Zone	Central Zone	Western Zone
50% Si	6.65c.	7.10c.	7.25c.
75% Si	8.05c.	8.20c.	8.75c.
80-90% Si	8.90c.	9.05c.	9.55c.
90-95% Si	11.05c.	11.20c.	11.65c.

Spot sales add: 45c. per lb. for 50% Si, .3c. per lb. for 75% Si, .25c. per lb. for 80-90% and 90-95% Si.

Silvery Iron

(Per Gross Ton, base 6.00 to 6.50 Si)

F.o.b. Jackson, Ohio	$29.50*
Buffalo	30.75*

For each additional 0.50% silicon add $1 a ton. For each 0.50% manganese over 1% add 50c. a ton. Add $1 a ton for 0.75% phosphorous or over.

*OPA price established 6-24-41.

Bessemer Ferrosilicon

Prices are $1 a ton above silvery iron quotations of comparable analysis.

Silicon Metal

OPA maximum base price per lb. of contained Si, lump size, f.o.b. shipping point with freight allowed to destination, for l.c.l. above 2000 lb., packed. Add .25c. for spot sales.

	Eastern Zone	Central Zone	Western Zone
96% Si, 2% Fe.	13.10c.	13.55c.	16.50c.
97% Si, 1% Fe.	13.45c.	13.90c.	16.80c.

Ferrosilicon Briquets

OPA maximum base price per lb. of briquet, bulk, f.o.b. shipping point with freight allowed to destination. Approximately 40% Si. Add .25c. for spot sales.

	Eastern Zone	Central Zone	Western Zone
Carload, bulk	3.35c.	3.50c.	3.65c.
2000 lb.-carload	3.8c.	4.2c.	4.25c.

Silicomanganese

Contract basis lump size, per lb. of metal, f.o.b. shipping point with freight allowed. Add .25c. for spot sales. 65-70% Mn, 17-20% Si, 1.5% max. C.

Carload, bulk	6.05c.
2000 lb. to carload	6.70c.
Under 2000 lb.	6.90c.
Briquets, contract, basis carlots, bulk freight allowed, per lb.	5.30c.
2000 lb. to carload	6.30c.
Less ton lots	6.55c.

Ferrochrome

(65-72% Cr, 2% max. Si)

OPA maximum base contract prices per lb. of contained Cr, lump size in carload lots, f.o.b. shipping point, freight allowed to destination. Add .25c. per lb. contained Cr for spot sales.

	Eastern Zone	Central Zone	Western Zone
0.06% C	23.00c.	23.40c.	24.00c.

Other Ferroalloys

Ferrotungsten, Standard grade, lump or ¼X down, packed, f.o.b. plant at Niagara Falls, New York, Washington, Pa., York, Pa., per lb. contained tungsten. 10,000 lb. of more	$1.90
Ferrovanadium, 50-55%, contract basis, f.o.b. producer's plant, usual freight allowances, per lb. contained Va.	
Open Hearth	$2.70
Crucible	$2.80
Primos	$2.90
Cobalt, 97% min., keg packed, contract basis, f.o.b. producer's plant, usual freight allowances, per lb. of cobalt metal	$1.50
Vanadium pentoxide, 88%-92% V_2O_5 technical grade, contract basis, any quantity, per lb. contained V_2O_5. Spot sales add 5c. per lb. contained V_2O_5	$1.10
Ferroboron, contract basis, 17.50% min. Bo, f.o.b. producer's plant with usual freight allowances, per lb. of alloy.	
2000 lb. to carload	$1.20
Under 2000 lb.	1.30
Per lb. alloy	$1.20
Ton lots	$1.25
Silcaz No. 3, contract basis, f.o.b. producer's plant with usual freight allowances, per lb. of alloy. (Pending OPA approval)	
Carload lots	25c.
2000 lb. to carload	26c.
Silvaz No. 3, contract basis, f.o.b. producer's plant with freight allowances, per lb. of alloy (Pending OPA approval)	
Carload lots	58c.
2000 lb. to carload	59c.
Grainal No. 1, f.o.b. Bridgeville, Pa., freight allowed 50 lb. and over, max. based on rate to St. Louis, per lb.	87.5c.
Bortram, f.o.b. Niagara Falls	
Ton lots, per lb.	45c.
Less ton lots, per lb.	50c.
Ferrocolumbium, 50-60%, contract basis, f.o.b. plant with freight allowances, per lb contained Cb.	
2000 lb. lots	$2.25
Under 2000 lb. lots	$2.30
Ferrotitanium, 40%-45%, f.o.b. Niagara Falls, N. Y., ton lots, per lb. contained titanium	$1.23
Less ton lots	$1.25
Ferrotitanium, 20%-25%, 0.10 C max., ton lots, per lb. contained titanium	$1.35
Less ton lots	$1.40
High-carbon ferrotitanium, 15%-20%, 6%-8% carbon, contract basis, f.o.b. Niagara Falls, N. Y., freight allowed East of Mississippi River, North of Baltimore and St. Louis, per carload	$142.50
Ferrophosphorus, 18% electric or blast furnace, f.o.b. Anniston, Ala., carlots, with $3 unitage freight equaled with Rockdale, Tenn., per gross ton	$58.50
Ferrophosphorus, electrolytic 23-26%, carlots, f.o.b. Monsanto (Siglo), Tenn., $3 unitage freight equalized with Nashville, per gross ton	$75.00
Ferromolybdenum, 55-75%, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained molybdenum	95c.
Calcium molybdate, 40%-45%, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained Mo	80c.
Molybdenum oxide briquettes, 48%-52% Mo, f.o.b. Langeloth, Pa., per lb. contained Mo	80c.
Molybdenum oxide, in cans, f.o.b. Langeloth and Washington, Pa., per lb. contained Mo	80c.
Zirconium, 35-40%, contract basis, f.o.b. producer's plant with freight allowances, per lb. of alloy. Add ½c. for spot sales	
Carload lots	14c.
Zirconium, 12-15%, contract basis, lump, f.o.b. plant with usual freight allowances, per lb. of alloy	
Carload, bulk	4.6c.
Alsifer (approx. 20% Al, 40% Si and 40% Fe), contract basis, f.o.b. Niagara Falls, carload, bulk	6.5c.
Ton lots	7.25c.
Simanal (approx. 20% Si, 20% Mn, 20% Al), contract basis, f.o.b. Philo, Ohio, with freight not to exceed St. Louis rate allowed, per lb.	
Car lots	8.75c.
Ton lots	9.25c.

HOW A SCRAP STORAGE BATTERY PINCH HIT FOR A NEW ONE

. . . A Salvage Story for Users of Industrial Trucks

A few years ago, an Edison Alkaline Battery, operating an industrial truck in a New England railroad terminal, was retired from service as "worn out." It had passed the usual "retirement age" and was beginning to show signs of no longer having adequate capacity for the work.

So the electrician in charge issued instructions to have it crated and shipped back to our factory for scrap credit. The battery was crated but in some unaccountable manner was not shipped. Instead, it was sidetracked into a corner of a dead storage room where it remained unnoticed for more than a year.

By lucky coincidence it was discovered again at a time when the terminal happened to be short of industrial-truck batteries. It was uncrated, charged, and put into one of the trucks just to see what it could do. It did so well that it was kept in regular use and was not finally replaced with a new one until more than a year later.

What this incident illustrates, more than anything else, is the fact that even after an alkaline battery reaches the normal end of its useful service life, and no longer delivers its full rated capacity, it is still a dependable power source, not in the habit of failing unexpectedly. Some of the unique characteristics of the Edison Alkaline Battery which account for this great reserve of dependability are cited in the column at the right.

ADVANTAGES OF THE EDISON ALKALINE BATTERY IN INDUSTRIAL TRUCKS AND TRACTORS

★ It is durable mechanically. High strength steel construction is used in the containers, grids, pole pieces, etc. The electrolyte is a preservative of steel.

★ It is foolproof electrically. It may be accidentally short-circuited, over-charged, over-discharged, or even charged in the reverse direction without injury.

★ It can be charged rapidly. It is not subject to finish-rate limitations. It requires no equalizing.

★ It withstands temperature extremes. It is not damaged by freezing. Free air spaces on all sides of all cells provide ventilation for rapid cooling under high temperature conditions.

★ It is simple to maintain. Merely charge adequately, add pure water, keep clean and dry.

★ Its tray assembly and cell connections are extremely simple.

★ Its life is so long that its annual depreciation cost is lower than that of any other type of storage battery.

Two Views on Postwar Employment

INDUSTRY, knowing that it has a job to do in connection with postwar employment that is fully as big as the wartime job it has so well done, should be interested in "expert" opinion on this subject.

The first thing that industry wants to know, because it is essentially practical, is "How big is the job going to be?"

You can get any number and kind of opinions on that subject, depending upon where you go to get it.

You might go to Stuart Chase, for example, author of "A Honeymoon Experiment" and other works on economy-social, political and otherwise. Chase, by the way, is said to be the President's favorite authority on economics. He is said to have frequently read this author before going to sleep, possibly for the same reason that I have sometimes taken Gibbon's "Rise and Decline of the Roman Empire" to bed with me.

Chase is what you might call a surrealist in economics. In this respect he parallels Salvador Dali in the field of art.

These surrealists have no use for details, or in other words, for facts. They paint with bold strokes, putting in neither background of factual data nor foreground of logic. Thus a piece of spaghetti, pictured as shooting the chutes at Coney Island, might well be labeled as a "noodle descending a staircase."

But to switch back from art to economics, we were discussing postwar employment. Here is what Stuart Chase, with his bold surrealistic strokes says, about it:

"If over 29 million . . . are to be turned suddenly into the labor pool, and if private industry is unable to absorb them quickly, our whole economic system will go into a downward spiral." (And then, hurrah boys, send in the fire alarm on Nov. 4 and summon the New Deal fire department.) Bang! It's just like that. On Tuesday we are sitting pretty and on Wednesday we have to provide new jobs for 29 million people!

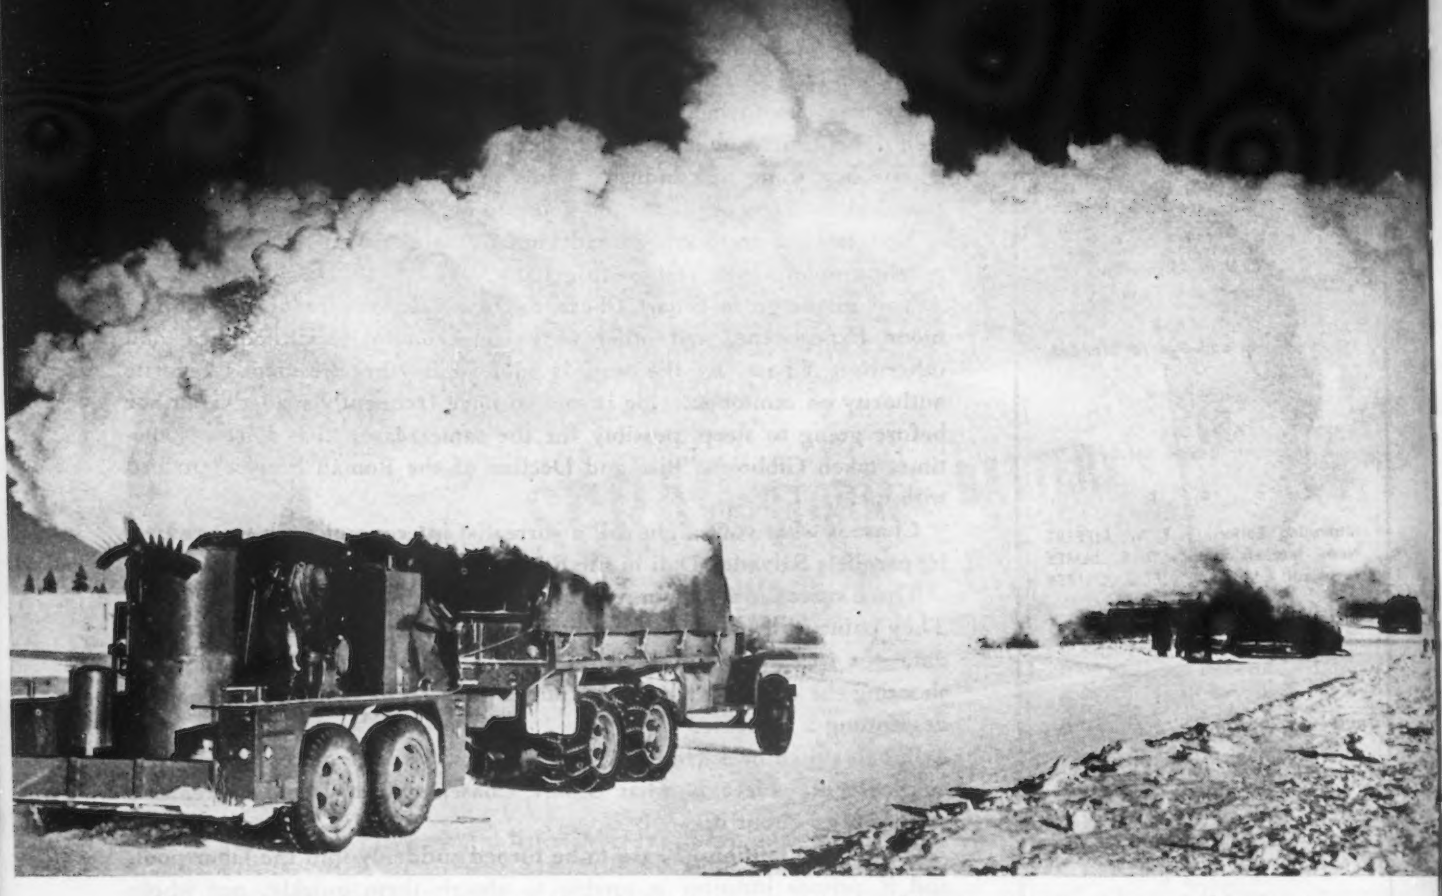
If you want to get the realist rather than the surrealist approach to this problem, it might be well for you to get a copy of "Post-War Re-Employment," by Karl T. Schlotterbeck, from the Brookings Institution, Washington. This is an institution that deals with facts and not with fancy.

Mr. Schlotterbeck in approaching his subject from the angle of probabilities rather than prophecies, takes into account the magnitude and the rate of demobilization, the withdrawals from the present labor market, the postwar outlook for employment and the outlook in the transition period. And his conclusions are summarized in the following words:

"Since there is good reason for believing that the level of production and employment will be for some years substantially above that of 1940, the outlook for satisfactory employment is distinctly encouraging."

To quote an expression: "You pays your money and you takes your choice." My choice is Schlotterbeck.

Blinding the Enemy with Clouds



This new generator blankets large areas with smoke made from materials ejected from special apparatus mounted on a trailer

—Another War Use of Inland Steel

Unusual clouds shrouded harbors and ports in North Africa and Sicily—man made clouds that reduced enemy artillery fire and bomber effectiveness by 85 per cent. They literally "blinded" the enemy and saved many American lives.

These strange clouds came from smoke generators that were developed by the Chemical Warfare Service of the U. S. Army Service Forces. Many of these generators were built by The Heil Company of Milwaukee. They can be used on landing barges and small craft, but are most often mounted on trailers towed behind fast trucks. Chemical Warfare Service smoke generator companies equipped with formations of these fog machines are even now blanketing Italian cities against aerial attack. One smoke unit covered the city of Palermo, Sicily, with smoke within 15 minutes after the starting signal was given.

Large shipments of Inland steel—plates, sheets, structurals, and 4-way floor plate—are used in these new mobile units, which generate smoke—obscuring enemy vision and bringing Victory closer at lower cost in lives and material. Devoted now to the production of steel for war, Inland is planning the production of steel for peace.

INLAND STEEL COMPANY

Sales Offices: Cincinnati • Detroit • Kansas City • Milwaukee • New York • St. Louis • St. Paul

The IRON AGE
MARCH 9, 1944

NEWS FRONT

► The latest Truman Committee report recommends that strict war controls be relaxed to permit smaller steel companies with idle capacity to seek "some civilian, non-essential business."

The committee also plugged the peacetime melting of National Emergency steels, contending that despite possible higher costs of some NE analyses, any wholesale return to the more complex alloy steels would again dangerously drain nickel and chromium supplies.

► Great Lakes vessel operators predict a possible opening for full fleet movement early in April, 19 days ahead of last year's beginning.

► High speed tool steel has gone through more erratic gyrations during the war than any other steel product. Considered the most critical of all metals right after Pearl Harbor, these tool steels now are practically a drug on the market.

Ordnance depots have some three or four months stock on hand which refuses to move. Even though this surplus, as measured in tons, is comparatively small compared with other steels that have piled up and still are accumulating, the disposal problem is becoming one of the most worrisome in the industry.

In 1942, with excessive domestic ordering and heavy British and Russian demands, ingot output of high speed steels topped 136,000 tons; 1943 production dropped below 80,000 tons; and, current output is at an even slower pace.

High-molybdenum low-tungsten analyses of high speed steels, of course, far outweighed the hitherto dominant high-tungsten (little or no molybdenum) tool analyses. In 1942 the former types accounted for some 82 per cent of the total, whereas in 1943 these molybdenum types made up about 65 per cent of the total.

► Although plastics production is expected to show slight improvement by the middle of the year, the supply situation will remain critical throughout 1944, leaving little for civilian allocations.

Gordon Lefebvre, president of Cooper-Bessemer Corp. foresees commercial airlines powered by diesel engines and burning furnace oil costing only 6c a gal. instead of high octane gasoline.

Charles E. Sorensen, vice-president and manufacturing head of the Ford Motor Co. has resigned, thereby moving Harry Bennett closer into the center of the Ford stage.

► Of the 59,760,000 tons of semi-finished and finished products shipped in 1943, the American Iron and Steel Institute reports that 19.1 per cent, or 11,433,000 tons, went to naval and merchant vessel shipbuilders. In the previous year, 9,440,000 tons were delivered.

Export tonnage under lend-lease went down slightly in 1943 to 14,158,000 tons, against 14,848,000 tons in 1942.

► German glider bombs are propelled by liquid fuel jets and released from an airplane flying parallel to its target. The bomb is released at a fairly low height and at a distance from three to four miles from the target.

The radio-controlled bomb has large fins, which cause it to be confused with the glider bomb. It is released at high altitude, well over 20,000 ft., and radio control is employed to improve accuracy.

Both types leave smoke trails, so that their trajectory may be followed. The airplane controlling either type cannot take rapid evasive action if attacked. Direct attack on the bomb itself has been successful in defense.

► Since the first of the year, about 1000 beehive coke ovens have been taken out of operation. Reasons given are the falling off in demand, increased production costs and consumer insistence on better quality.

► Sunday supplement enthusiasm for helicopters leaves the experts cold. One expert thinks the helicopter, as it stands today, has not progressed beyond "an advanced state of pure research."

. . . Forecasting Tool and

By SERGIUS D. BROOTSKOOS
Mechanical Engineer, Washington, D. C.

o o o

THE procurement of expendable tools, dies, jigs, fixtures and gages has always been a considerable headache for men in charge of production work. The determination as to what quantities of expendable tools and gages must be held in stock in the plants in order to assure uninterrupted production is usually based on the previous personal experiences of the shop management.

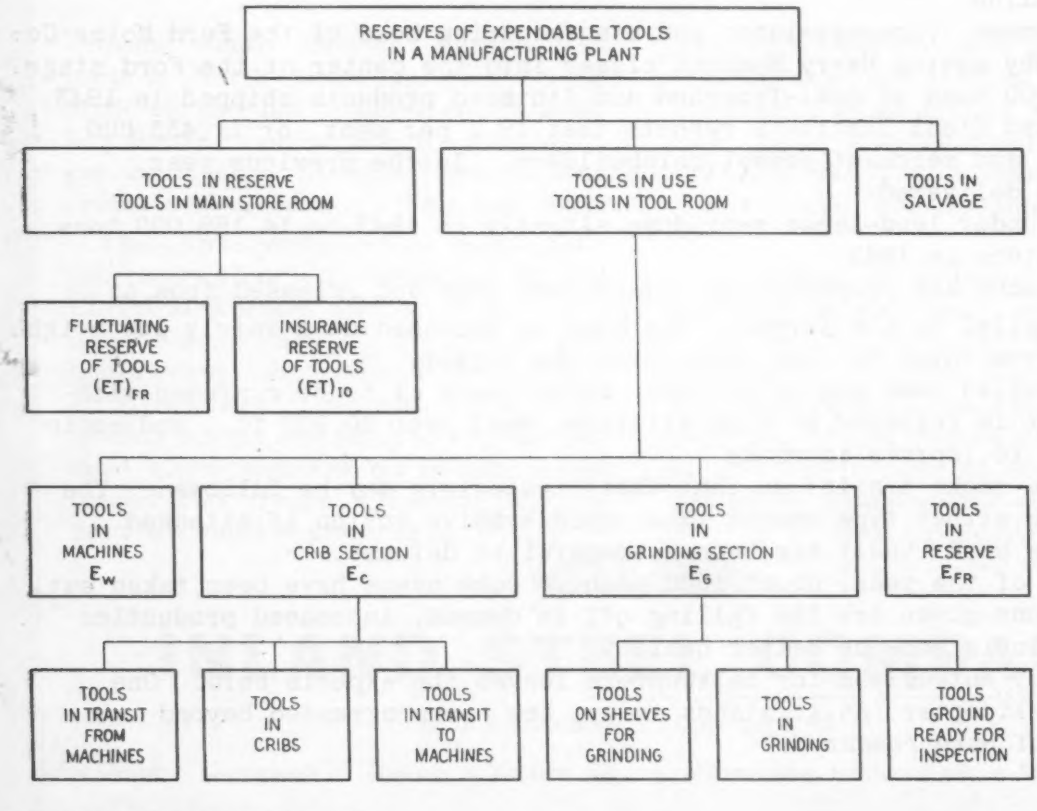
In times of great industrial upheavals, as well as during war times, these experiences may lead either to underestimation of the requirements of tools, which may endanger the production schedules, or to overestimation, which may in turn lead to overstocking and unnecessary investments in tools.

However, by blending personal experiences with the knowledge of laws governing tool procurement, the shop management may determine beforehand with a sufficient degree of accuracy and surety the number of tools and gages which must be held in the plant store room and tool rooms. The knowledge of these laws would place the procurement of expendable tools and gages on a firm foundation and make it less dependable on personal experiences of tool buyers. It would also permit intelligent supervision by plant managers of stocks on hand, and control the requisitions by tool rooms, and purchasing orders.

Requirements of Expendable Tools

The determination of production methods and types and numbers of machine tools to be used, as well as of the general tooling-up of the job is usually done by the planning and production departments of the plants. After their work is completed and approved by the management, additional machine tools are procured on the basis of monthly production schedules. The number and the type of the selected machine tools determine the design and procurement of the necessary jigs and fixtures which insure the interchangeability of the parts to be produced.

The selection of machine tools and the jigs and fixtures in turn determines the types and quantities of the necessary expendable tools. The procurement of these tools, however, cannot be based exclusively on total or even on monthly production requirements because expendable tools, as their name implies, are replaced only when they are worn out, get dull, or break. Procurement of these tools in bulk and at one time may command low prices, but will tie up too large a part of the working capital of the plant. Furthermore, large stocks of expendable tools require large storage space which increases rent costs or real estate taxes; involve more supervision and overhead costs, and finally, increase the danger of rusting and pilferage. Hence, procurement of the total estimated number of expendable tools at one time may in the end become more costly than buying the



o o o

FIG. 1—The distribution of expendable tools in individual tool rooms showing tools in reserve, tools in use and those in salvage.

o o o

Gage Requirements . . .

. . . Tools that are to be used in the shop tool rooms and those that should be held in reserve in the main store room can be accurately estimated by applying simple mathematical rules. In this article the author develops formulas in which he substitutes symbols for figures that should be used to forecast tool purchases, and in the concluding article next week, an example of the application of the formulas is presented.

tools in partial lots large enough to assure uninterrupted operation of all machines in the plant and to warrant reasonably low prices.

The procurement of expendable tools must, therefore, be based on accumulating and keeping only such reserves of tools which would:

a. **Insure uninterrupted operation of all machines in the plant;**
b. **Insure reserves of tools in the main store room ample enough to take care of timely deliveries to all tool rooms in the plant;**
c. **Permit buying of these tools in lots that would warrant reasonably low prices.**

The stocks of available expendable tools in a plant are found in:

1. **The main store room: Tools in Reserve;**
2. **The tool rooms of individual shops: Tools in Use;**
3. **The tool salvaging shop: Salvaged Tools.**

Assuming that the resharpening and reconditioning of expendable tools is done in individual tool rooms, the distribution of these tools could be presented by a chart such as shown in Fig. 1.

The basic principles for calculating tool requirements were first advanced by S. A. Dumler, a Russian engineer, in his article "Calculation Methods for Tool Reserves," published in 1937 in the magazine, THE METAL INDUSTRY HERALD. *However, his presentation of these principles was made to suit conditions in the metal working industries of his country.*

Tools in Use

Number of Expendable Tools in the Machines: The latest tendency in manufacturing plants is to supply every machine operator with only one set of working tools. The replacement of worn, dull or broken tools is done exclusively by the tool setters. Therefore, the number of the particular expendable tools in actual use in the machines of a certain type can easily be ascertained on the basis of the total number of these machines used in the shop.

The number of machines needed for each machining operation is determined by the formula:

$$m = \frac{Pt_m}{T_m} \qquad (1)$$

where

m = Number of machines of a selected type to be used for a particular operation

P = Monthly output of parts to be machined

t_m = Time, in hours, required for machining a specific part in the machine of selected type

T_m = Accepted "actual" working time, in hours, per month, of machines in the plant (usually 75 per cent of the total working machine hours per month).

The number of expendable tools at work in the machines is then

$$E_w = mk = \frac{Pt_m}{T_m} k \qquad (2)$$

where

E_w = Number of tools at work in the machines

K = Number of identical tools, if any, used in each machine.

In order to keep all machines in the shop in continuous operation the tool room must keep a stock of replacement tools. Those tools which are in usable condition are kept in the crib section of the tool room ready to be handed to the tool setters in exchange for a dull or broken tool; the worn or dull tools which can be resharpened are sent to the grinding section of the tool room.

Number of Tools in the Crib Section: The minimum number of usable replacement tools to be kept in the

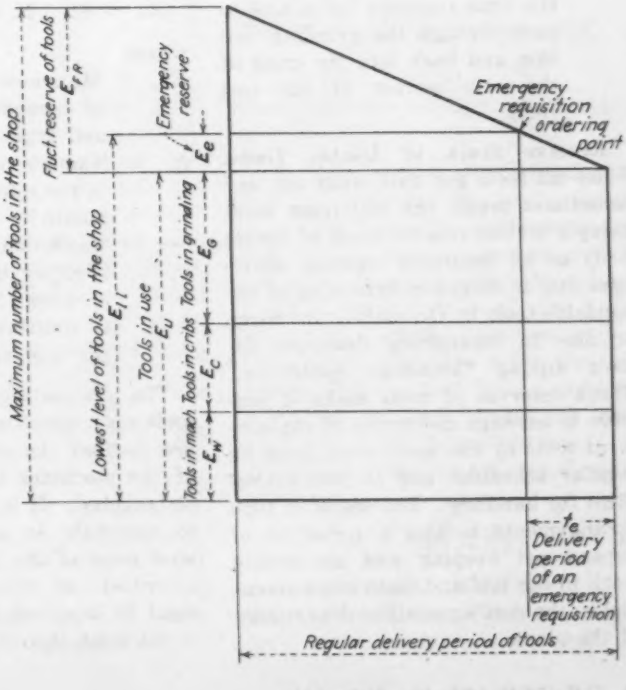


FIG. 2—Classification of "tools in use" in the shop, including tools at work in machines, tools in the crib and tools being reground. The ordering point for emergency requisition of tools from the main store room is indicated.

crib section in relation to that already at work in the machines depends on the ratio of the "working cycle" of the tools to their average working time in the machines:

$$\frac{E_c}{E_w} = \frac{t_c}{t_w}$$

$$E_c = \frac{t_c}{t_w} E_w = \frac{t_c}{t_w} mk \qquad (3)$$

where

E_c = Number of expendable tools to be kept in the crib section

t_c = Working cycle of a tool, in hours; it is the time it takes a tool to leave its crib, reach the machine, be set in the machine, perform its work, and be returned to the tool room for resharpening or scrapping

t_w = Average working time of a tool in a machine between grindings.

Number of Tools in the Grinding Section: The worn and dull tools returned to the tool room in exchange for new ones are sent either to the grinding section for resharpening or to the salvaging shop, or they are scrapped altogether. The permissible maximum number of tools to tbe held in the grinding section in relation to that in the crib section of the tool room must be in direct proportion of the grinding time to the working cycle of the tool:

$$\frac{E_g}{E_c} = \frac{t_g}{t_c}$$

$$E_g = \frac{t_g}{t_c} E_c = \frac{t_g}{t_c} \times \frac{t_c}{t_w} mk$$

$$= \frac{t_g}{t_w} mk \qquad (4)$$

where

E_g = Number of expendable tools in the grinding section;

tg = Grinding time in hours; it is the time required for a tool to pass through the grinding section and back into the cribs of the crib section of the tool room.

Reserve Stock of Usable Tools: Since all tools get dull, wear out and sometimes break, the tool room must carry a limited reserve stock of usable tools as an insurance against shortages due to delays in deliveries of expendable tools by the main store room, or due to emergency demands for tools during "breakage epidemics." These reserves of tools make it possible to arrange deliveries of replacement tools by the main store room on regular schedules and in lots convenient for handling. The result of such arrangements is also a reduction of paper, cost keeping and accounting work in the tool and main store rooms and in the cost accounting department of the plant.

Hence, the total number of usable tools available in the tool room varies from a maximum at the time of delivery of a fresh shipment of tools to a minimum which is indispensable for continuous work of the machines in the shop and which consists of tools in the machines and in the crib and grinding sections of the tool room. The calculation of this minimum stock of expendable tools in actual use has been discussed above.

The reserve stock of usable tools in the tool room may, therefore, be called the "fluctuating reserve" of tools. In determining the size of this fluctuating reserve of tools it must be kept in mind that shipments of large lots of tools from the main store room to the tool room necessitate the use of large bins or of long and deep shelves. On the other hand, deliveries of tools in small lots cause more frequent shipments, higher transportation costs, more paper work, and may even endanger production in case of unforeseen delays by the main store room of the plant in filling out the requisitions.

The size of tool lots for delivery to the tool rooms should be based on calculations of overhead costs involved: rent, light, upkeep of tools in the store and tool rooms, paper work and inside plant transportation. These overhead costs can be ascertained quite precisely, but the general practice in most manufacturing plants is to make deliveries of expendable tools to the tool rooms a weekly, bi-weekly or monthly shipment.

The fluctuating reserve of expendable tools of one size and type in the tool room may now be expressed by the formula:

$$E_{FR} = (E_w + E_c + E_g)\, a = aE_m \qquad (5)$$

$$E_m = E_w + E_c + E_g \qquad (6)$$

where

E_{FR} = Maximum fluctuating reserve of expendable tools of one size and type in the tool room

E_m = Number of certain tools used in the selected machines in one month

a = Coefficient, the value of which is either ¼, ½ or 1 depending on weekly, bi-weekly or monthly deliveries of new tools to the tool rooms.

The fluctuating reserve of usable tools may sometimes run dangerously low so that the continuous operation of the machines in the shop may be endangered. It is therefore advisable to ascertain in advance the lowest level point of the stock of usable tools at which an emergency requisition must be sent out from the tool room to the main store room. It takes time even for an emergency requisition to pass through the usual red tape in the various offices of the plant, to have the requisitioned tools assorted, packed and sent to the toolroom which originated the requisition.

The lowest level of reserve tools in the tool room may be considered to be equal to the number of tools which may reasonably be requested by the tool setters while an emergency requisition is being filled. This emergency reserve stock of tools therefore must be proportional to that in the crib section. This proportion in turn equals the ratio of the average length of time which it usually takes for an emergency requisition to materialize, to that of the working cycle of the tools, to wit:

$$\frac{E_e}{E_c} = \frac{t_e}{t_c}$$

$$E_e = \frac{t_e}{t_c} E_c = \frac{t_e}{t_c} \times \frac{t_c}{t_w} mk$$

$$= \frac{t_e}{t_w} mk \qquad (7)$$

where

E_e = Number of tools which may be required by the tool setters while an emergency requisition is being filled out

t_e = Average time, in hours, between the issuance of an emergency requisition and the delivery of the tools to the tool room.

The lowest level of usable tools in the shop and the tool room when an emergency requisition must be issued is then equal to:

$$E_{ll} = E_w + E_c + E_g + E_e = E_m + E_e \qquad (8)$$

All above formulas can easily be expressed in terms of monthly production requirement figures. The total number of expendable tools of one type and size to be used in a manufacturing plant in one month for a certain machining operation can be determined beforehand by a general formula:

$$E_m = \frac{Pt_mK}{t_w\left(g+1\right)\left(1-\frac{l}{100}\right)} \qquad (9)$$

where

E_m = Number of certain tools used in the selected machines in one month

P = Monthly output of parts to be machined

t_m = Time, in hours, required for machining each part in the selected machines

K = Number of identical tools, if any, used in each machine

t_w = Average working time, in hours, of a tool between grindings

g = Average number of grindings before the tool is turned over to the salvaging department or is scrapped altogether

l = Percentage of losses and breakages of tools in the shop.

The number of expendable tools held in the crib and grinding sections of the tool room, including the emergency reserve stock, can then be expressed in terms of general monthly tool requirements as follows:

$$E_c = x\,E_m \tag{10}$$

$$E_g = y\,E_m \tag{11}$$

$$E_e = z\,E_m \tag{12}$$

where x, y, and z, are certain coefficients. Using the formulas 1, 2, 3, 4, and 7, the values of these coefficients are:

$$x = \frac{E_c}{E_m} = \frac{t_c}{t_w}\,mk \times \left[\frac{t_w\left(g+1\right)\left(1-\frac{l}{100}\right)}{Pt_mk}\right] = \left(\frac{t_c}{t_w} \times \frac{Pt_m}{T_m}\,k\right) \times \left[\frac{t_w\left(g+1\right)\left(1-\frac{l}{100}\right)}{Pt_mk}\right] = \frac{t_c}{T_m}\left(g+1\right)\left(1-\frac{l}{100}\right) \tag{13}$$

$$y = \frac{E_g}{E_m} = \frac{t_g}{t_w}\,mk \times \left[\frac{t_w\left(g+1\right)\left(1-\frac{l}{100}\right)}{Pt_mk}\right] = \left(\frac{t_g}{t_w} \times \frac{Pt_m}{T_m}\,k\right) \times \left[\frac{t_w\left(g+1\right)\left(1-\frac{l}{100}\right)}{Pt_mk}\right] = \frac{t_g}{T_m}\left(g+1\right)\left(1-\frac{l}{100}\right) \tag{14}$$

$$z = \frac{E_e}{E_m} = \frac{t_e}{t_w}\,mk \times \left[\frac{t_w\left(g+1\right)\left(1-\frac{l}{100}\right)}{Pt_mk}\right] = \left(\frac{t_e}{t_w} \times \frac{Pt_m}{T_m}\,k\right) \times \left[\frac{t_w\left(g+1\right)\left(1-\frac{l}{100}\right)}{Pt_mk}\right] = \frac{t_e}{T_m}\left(g+1\right)\left(1-\frac{l}{100}\right) \tag{15}$$

Since the number m of selected machines is known and since the monthly consumption of tools E_m and the coefficients x, y and z can be determined with a sufficient degree of approximation in advance, the maximum and the minimum number of usable tools to be held in the tool rooms for each type of machines can easily be ascertained. The classification of tools held in the shop tool rooms are graphically presented in Fig. 2.

Tools in Reserve

All figures of current and future requirements of various tool rooms for expendable tools are collected and segregated by the production department according to their types, sizes and the time when these tools are required. Either tables or charts are compiled to determine the reserves of expendable tools to be accumulated and held in readiness at the main store room of the plant for insuring timely delivery to the various tool rooms. On the basis of these data the purchasing department shapes its procurement policy. Standard tools are usually bought from outside manufacturers while special tools are either made in the tool shop of the plant, if it has one, or they are ordered from contract die and tool shops which specialize in making tools to order.

The accumulated reserves of tools in the main store room can be divided in two groups in order to assure smooth operation of all shops in the plant as well as of the purchasing and cost accounting departments as follows:

1. **Fluctuating reserve**
2. **Insurance reserve**

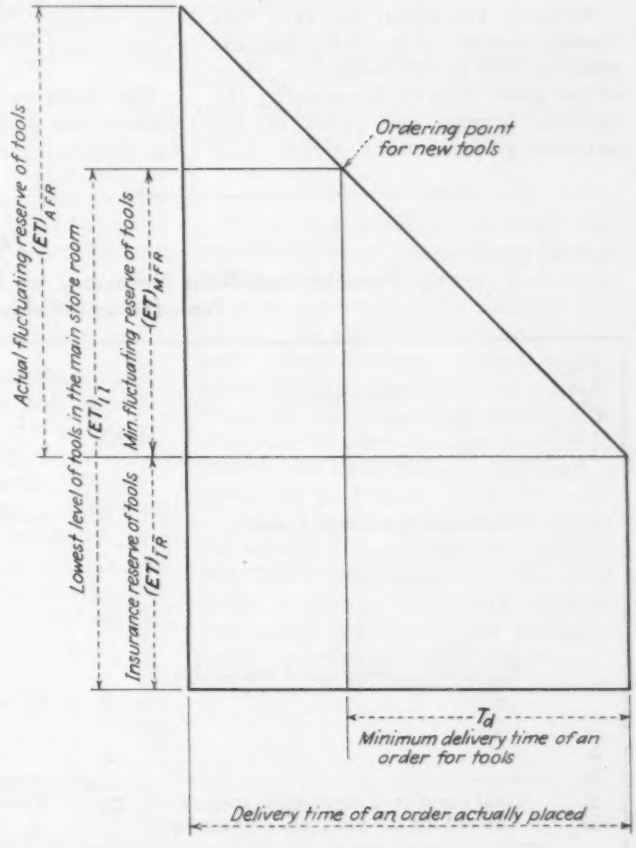

FIG. 3 — Expendable tools held in reserve in the main store room, showing the ordering point for new tools.

The fluctuating reserve is the stock of individual expendable tools from which all tool rooms requisitions are filled. It is at its maximum when a new shipment of tools arrives at the main store room and it is exhausted when it reaches the level of the insurance reserve.

The insurance reserve is the stock of individual expendable tools which must be kept in the main store room of the plant as a precaution against any delays in deliveries of the ordered tools by suppliers, as well as against "breakage epidemics," which may place undue pressure on the main store room for deliveries of replacement tools.

The procurement and deliveries of expendable tools from the suppliers as well as from the plant's own tool shop should always be arranged in lots equal to or in multiples of the monthly requirements of the tools. Since the monthly requirements of individual expendable tools and the average delivery time by the suppliers or the tool shop are known, the minimum size of the fluctuating reserve of each tool, can now be expressed by the formula:

$$(ET)_{MFR} = E_m\,T_d \tag{16}$$

where

$(ET)_{MFR}$ = Minimum size of the fluctuating reserve of an ex-

pendable tool in the main store room of the plant

T_d = Average time, in months, consumed from the issuance of the requisition until the receipt of the tools by the main store room of the plant. This includes the time consumed by the red tape in various departments of the plant, the time for getting the bids and issuing the orders and the average time of delivery of the tools by the supplier.

However, the actual size of a fluctuating reserve of an individual expendable tool in the main store room of the plant must be governed by the business acumen and policy of the purchasing department which may find it more advantageous to order the needed tools for several months in advance. In case the plant has its own tool shop, the maximum size of the fluctuating reserve of a particular tool is governed by its production costs.

The actual size of the fluctuating reserve for an expendable tool can now be expressed by the formula:

$$(ET)_{AFR} = bE_m T_d \qquad (17)$$

where

$(ET)_{AFR}$ = Actual size of the fluctuating reserve for an expendable tool in the main store room of the plant

b = Coefficient, the upper and lower limits of which will be determined later.

The issuance by the main store room of the plant of a requisition to the purchasing department for a new stock of an expendable tool is determined by its level in the bins or on the shelves in the store room. The stock reaches this level when the available number of the particular tool equals to:

$$(ET)_{ll} = (ET)_{MFR} + (ET)_{IR} \qquad (18)$$

where

$(ET)_{ll}$ = Number of available tools at its lowest level in the bins or on the shelves of the main store room when a requisition must be issued

$(ET)_{IR}$ = Insurance reserve of the same tool to be held in stock in the main store room of the plant.

The size of this insurance reserve can easily be determined by taking into consideration the two major causes which make the accumulation

TABLE I

Formulas and Data Necessary for Determining the Number of Expendable Tools for an Individual Machining Operation

Location of Tools	Description	Mathematical Formulas		Necessary Data
		No.	Expression	
SHOP	Number of machines at work	1	$m = \frac{Pt_m}{T_m}$	P = Monthly output of parts t_m = Actual machining time, hours T_m = Actual working time of the shop, hours per month
SHOP	Monthly requirements of expendable tools	9	$E_m = \frac{Pt_m k}{t_w (g+1)\left(1 - \frac{l}{100}\right)}$	K = Number of identical tools in a machine t_w = Working time of a tool in a machine, hours g = Number of grindings before the tool is sent to the salvaging department l = Percentage of losses and breakages of tools in the shop
SHOP	Total number of expendable tools required for the production program	22	$E_t = E_m T_p$	T_p = Planned production time, months
SHOP	Fluctuating reserve of expendable tools in the tool room	5	$E_{FR} = a E_m$	Coefficient which depends on delivery periods of tools to the tool room
SHOP	Emergency reserve of expendable tools in the tool room	12	$E_e = zE_m = E_m \frac{t_e}{T_m}(g+1)\left(1 - \frac{l}{100}\right)$	t_e = Time needed for an emergency requisition to materialize, hours
SHOP	Lowest level of tools in the shop and its tool room when an emergency requisition must be issued	8	$E_{ll} = E_m + E_e$	
MAIN STORE ROOM	Minimum fluctuating reserve of expendable tools	16	$(ET)_{MFR} = E_m T_d$	T_d = Time needed for a store room requisition to materialize, hours
MAIN STORE ROOM	Insurance reserve of expendable tools	19	$(ET)_{IR} = E_m T_d (cd - 1)$	c = Coefficient for "breakage epidemics" d = Coefficient for delivery delays
MAIN STORE ROOM	Lowest level of tools in the store room when a requisition must be issued	20	$(ET)_{ll} = (ET)_{MFR} + (ET)_{IR}$	
MAIN STORE ROOM	Minimum size of an initial order for expendable tools	21	$(ET)_{1.0} \geqq E_m (1 + a + edT_d)$	

of it obligatory: First, that a breakage epidemic may be expected in the shop, and second, that the supplier may fail in his promised deliveries. The monthly consumption of expendable tools due to the breakage epidemic may be expressed in terms of regular monthly consumption of tools, as:

$$c\,E_m$$

where the coefficient c is larger than unity ($c > 1$).

The time of delivery under the second condition would then be:

$$d\,T_d$$

where the coefficient d is larger than unity ($d > 1$).

In such a case a new requisition must be of the size:

$$c\,E_m \times d\,T_d = cd\,E_m\,T_d$$

The size of the insurance reserve is then:

$$(ET)_{IR} = cd\,E_m\,T_d - E_m\,T_d = E_m\,T_d\,(cd-1) \quad (19)$$

A requisition for new tools must thus be issued when the fluctuating and insurance reserves in the main store room reach the level:

$$(ET)_{II} = (ET)_{MFR} + (ET)_{IR} = E_m\,T_d + E_m\,T_d\,(cd-1) = cd\,E_m\,T_d \quad (20)$$

The average values of the coefficients c and d are:

$$1.1 \leqq c \leqq 1.3$$
$$1.1 \leqq d \leqq 2.0$$

We will now determine the minimum size of the initial procurement of expendable tools $(ET)_{1\cdot0}$ which should insure uninterrupted production in the plant. This initial procurement must be of such magnitude as to cover the requirements in tools of the shop and the minimum reserves of them in the tool room and also in the main store room of the plant. This can be expressed by the formula:

$$(ET)_{1\cdot0} \geqq E_m + E_{FR} + (ET)_{II}$$
$$E_M + E_{FR} + (ET)_{II} = E_m + aE_m + cd\,E_m\,T_d = (1 + a + cd\,T_d)\,E_m$$
$$(ET)_{1\cdot0} \geqq (1 + a + cd\,T_d)\,E_m \quad (21)$$

The total (maximum) requirements of each tool for the contemplated production program is:

$$E_T = E_m\,T_p \quad (22)$$

where

E_T = Total number of each tool required for the contemplated production program

E_m = Monthly requirements of each tool

T_p = Time, in months, of the contemplated production program.

Hence the purchasing department knowing the maximum and minimum requirements for each tool is in a position to plan its search for the best prices and delivery terms.

After the initial order for the tools has been placed, the consecutive procurement orders of tools for the fluctuating reserve in the main store room of the plant are based on formula 17:

$$(ET)_{AFR} \equiv bE_m\,Td$$

The maximum value of the coefficient b when only one additional order for tools will be placed is then:

$$bE_m\,T_d \leqq E_T - (ET)_{1\cdot0} \quad \text{or}$$
$$bE_m\,T_d \leqq E_m\,T_p - (1+a+cd\,T_d)\,E_m$$
$$b \leqq \frac{1}{T_d}\,[T_p - (1+a+cd\,T_d)] \quad (23)$$

If several consecutive procurement orders for the same tool were placed for keeping up this fluctuating reserve the sum of all coefficients, b′, b″, b‴, etc., then used must always be:

$$b' + b'' + b''' \ldots\ldots \leqq b \quad (24)$$

This will exclude any possibility of ordering superfluous tools and will assure the full use of all procured tools in the actual production work.

Tools in Salvage

It is impossible to forecast the number of tools which the salvaging department may salvage and turn over to the main store room of the plant. The salvaged tools are, therefore, pure savings which permit slight fluctuations in current requisitions for additional expendable tools. The classification of expendable tools held in the main store of the plant is presented by Fig. 3.

Table I gives a summary of formulas which are necessary for determining the requirements in expendable tools. It also presents such information and data which are indispensable for solving these formulas.

(To be concluded)

Polythene—A New Du Pont Plastic

POLYTHENE is the generic name for a new tough plastic manufactured by the polymerization of ethylene. In announcing that polythene is now being manufactured in commercial quantities, E. I. du Pont de Neumours & Co., Inc., emphasizes that the material is available in substantial quantities only by specific allocation for war purposes. The original development work was done by Imperial Chemical Industries, Ltd.

Supplies of polythene heretofore available have gone into production of items urgently needed by the armed services, where this new plastic has demonstrated its advantages as a covering for electric wiring and cable.

Outstanding properties upon which it is expected that many important uses will be based include flexibility and toughness over a wide range of temperatures, unusually good resistance to water and to penetration by moisture, chemical inertness and excellent electrical properties. Possible future uses for polythene, when available, will be various types of containers, including collapsible tubes for food and cosmetics; gaskets and battery parts; flexible tubing or more rigid piping; waterproof and chemically resistant coatings, and adhesives for general industrial use.

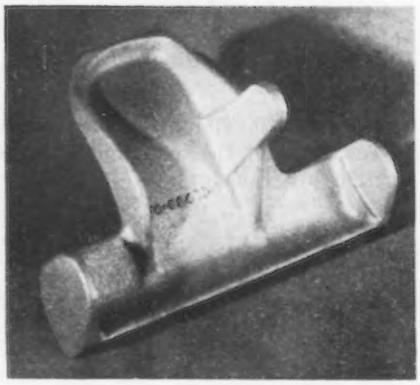
In thin sections, Polythene may be classified as non-rigid, yet it does not have the limp rubbery quality that characterizes most non-rigid plastics. However, thick specimens exhibit sufficient stiffness to warrant classification of the material among the more rigid plastics.

The new plastic is readily molded and fabricated by present methods with existing molding and shaping equipment. It can be extruded, injection molded, compression molded and calendered. In sheet, rod or tube form it can be machined, cut, blown, blanked or swaged.

Castings and Forgings Replace

MUCH has been written in the past few years about the extension of the use of welding, and rightly so, because without the development of welding techniques during the past two years the war effort would not have progressed nearly so far nor so fast. However, with the increase in welding came the need for experienced welders by the thousands, a difficulty that was partly overcome by quick training of anyone willing and able to hold a torch or electrode in shops all over the country.

Especially did the aircraft industry find it difficult to obtain welders in the numbers required. This difficulty, along with a few others connected with welding, led the Stinson Division of Consolidated Vultee Aircraft Corp., at Wayne, Mich., to move toward the use of castings and forgings to eliminate the necessity of welding as quickly as the design of one of the Stinson ships, the L-5, became standardized or "frozen."



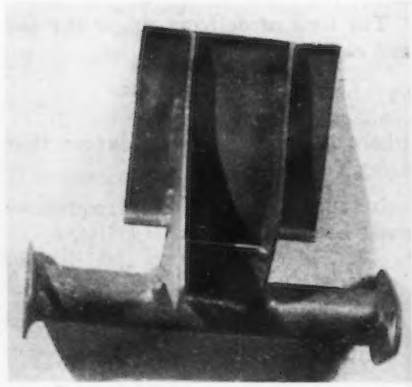


FIG. 1—The cast aluminum brake pedal, left, replaced the welded assembly at right. In addition to saving considerable welding and forming, rejections were reduced to nothing.

Some examples of the substitution of forged and cast parts for welded assemblies are shown in the accompanying illustrations. Fig. 1 shows a cast aluminum brake pedal that was substituted for a welded steel pedal made up of seven parts. This eliminated 19 in. of welding and five machining operations.

Fig. 2 illustrates how a six-piece welded part was eliminated by a one-piece cast aluminum part, shown at the left. This flap bellcrank formerly required 5 in. of welding, and in the new design five machining operations were cut out. Likewise, the forged part shown above in Fig. 3 replaced the seven piece welded assembly below. Five machining operations were eliminated in the new design, as were 23 in. of welding.

To change an aircraft design from welded parts to cast or forged parts, there must be serious consideration given many factors. The change must be feasible from an engineering standpoint. The design must be frozen so as to justify the cost of making dies or patterns. The castings or forgings must be available in desired quantities, the latter of which are still difficult to obtain with any reasonable delivery Last, but not least, it must be economical.

In spite of all the "ifs" of such changes, Stinson found that cast and forged parts are highly satisfactory and economical. From the standpoint

TABLE I

• Comparative Costs of the Welded and the Aluminum Cast Bellcrank Assembly Wing Flap Control for the Stinson L-5. Time shown is in manhours per ship, with two assemblies per ship.

	Welded Steel Assembly	Cast Aluminum Assembly
Based on Normal Efficiency of Operations		
Direct Labor, 2.1 hr. at $1.20 per hr.	$2.520	$0.328
Overhead, at 150 per cent of labor cost	3.780	0.493
Material	0.320	2.000
Tool cost at $700 amortized over 1500 ships*	.....	0.467
Total	$6.620	$3.288
Standard Cost Based on 100 per cent Efficiency		
Direct Labor, 2.1 hr. at $1.20 per hr.	$2.520	$0.33
Overhead, at 150 per cent of labor cost	3.780	0.49
Material	0.320	2.00
Tool cost at $700 amortized over 1500 ships*	.....	0.47
Scrap loss	.380	....
Total	$7.00	$3.29
Standard Cost Based on 50 per cent Efficiency		
Direct Labor, 2.1 hr. at $1.20 per hr.	$5.04	$0.66
Overhead, at 150 per cent of labor cost	7.56	0.98
Material	0.32	2.00
Tool cost at $700 amortized over 1500 ships*	....	0.47
Scrap loss	.65	....
Total	$13.57	$4.11

* Original cost of welding jigs and fixtures not shown.

Aircraft Weldments . . .

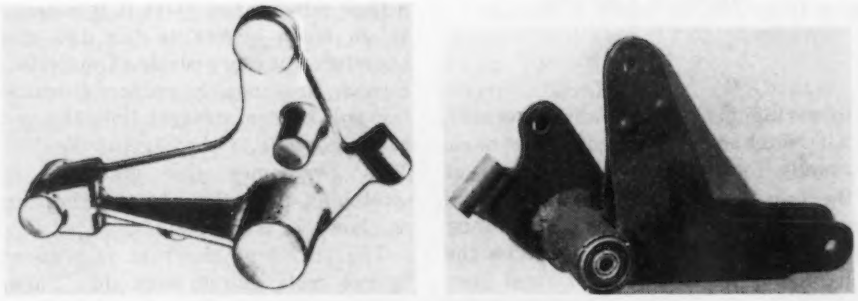

FIG. 2—This one-piece cast bellcrank (left) eliminated the six-piece welded part shown on the right. Cost breakdowns for making each of these parts are shown in the accompanying table.

of cost, it can be seen from Table I that in the case of the bellcrank assembly for the wing flap controls, the casting is considerably cheaper than the former method of welding. Even without including the costs of the original jigs and fixtures for welding, the aluminum cast part ran about 50 per cent less than the cost of welding the assembly. This has been borne out in practically every one of about a dozen such changeovers.

Other reasons prompting the switch to cast or forged parts where possible in the Stinson L-5, which is known as the "Flying Jeep" and used for Army liaison work and artillery directing, were: High scrap losses encountered in welding, poor tolerance control, because of shrinking of the tubular structures after cooling; the difficulty of inspecting the weld; and the ease with which less experienced welders burned through the light tubing of the fuselage frame.

Whether the use of such parts replacing welding will become widespread in the aircraft industry depends largely upon how quickly designs of given planes will be stabilized. It would be impractical to make forging dies for a given part in a plane if within a few months the design would be changed and the part would either have to be made differently or be completely eliminated.

Both forgings and castings have been difficult to obtain, some of them coming to Wayne from as far away as Denver, Colo., but the program has been set up and many of these difficulties are gradually being ironed out. It is believed that before long most of the supply problems will be eliminated and a reasonably free flow of required forged and cast parts will be coming into the plant without undue interruptions.

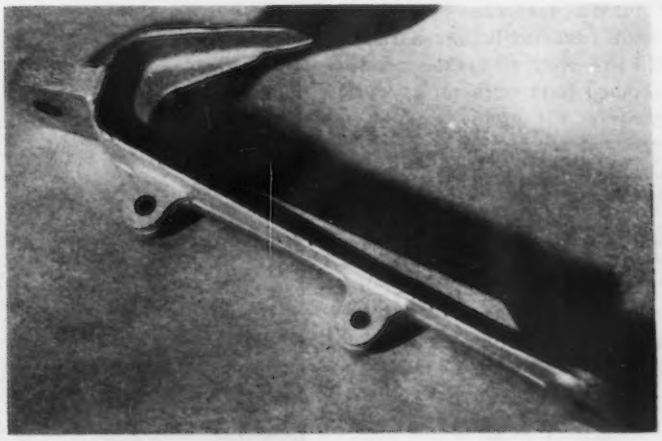

FIG. 3—The intricate forging shown on the above replaced a seven-piece welded assembly below. This assembly, a lower lift strut fitting, required 23-in. of welding and in addition, five facing and machining operations were eliminated.

. . . Stretch Forming

By R. H. RUUD
Assistant Factory Manager
North American Aviation, Inc.
Inglewood, California

o o o

STRETCH-forming of sheet metal has become a major process at North American Aviation, Inc. Starting with the installation of an Erco stretching machine in September, 1941, developments have progressed until at present a number of nacelle skins, landing gear door skins, cowl sheets and fuselage skins are being formed by stretching. Some parts are *partly* stretched prior to the drop hammer operation, thus eliminating much time and rubber which would have to be used if parts were made entirely on the drop hammer.

In the beginning, a number of forms were made from wood but it was found that it required too much work on these forms to obtain a properly contoured part. Hence dies of wood or plastic material have been abandoned in favor of hollow Kirksite dies which are easy to make and deliver a finished part with no re-work necessary.

For data on casting of hollow Kirksite dies see the following articles in THE IRON AGE: *"Coring Kirksite Dies," April 8, 1943, and "Kirksite Die Casting Technique," June 10, 1943. For data on stretch forming see "Stretch Forming Contoured Sheet Metal Aircraft Parts," June 10, 1942, and "Stretch Forming Speeds Aircraft Production," Oct. 1, 1942.*

The belief has been proved false that relatively flat skins cannot be stretched unless the form is made in a small arc and parts are expected to spring back to the shape wanted. All North American's dies are made exactly to the shape and contour of the finished part, and do not depend upon any spring-back (Fig. 1). Many improvements have been made on the stretching machine. The original jaws shown in Fig. 2 have been replaced by the swivel jaws shown in Fig. 3. This photograph also shows the graduated scales placed on the base to indicate the position of the jaw beams, thus cutting down the setup time considerably when repeating jobs at odd intervals. The swivel jaws have a dual advantage: First it is possible to go much nearer to the dies and therefore cut down waste of material; second, breakage is reduced because the pull is in a straight line, tangent to the contour at the edge of the dies. This overcomes the difficulty of stretching over the edge of the dies as shown in Fig. 1.

The travel of the ram is reduced by two rests, one on each side. These rests stop the ram from going down any farther than is required to clamp the sheets.

For the past several months North American has been using a clad

o o o

BELOW

FIG. 1—Shown here is a stretching die that is made exactly to the dimensions of the finished part. No subsequent springback is allowed for. There was some difficulty in stretching over the edge of the dies; this was corrected by the improved jaws shown in Fig. 3. Note the large radius and hence flat contour of the arc in both directions.

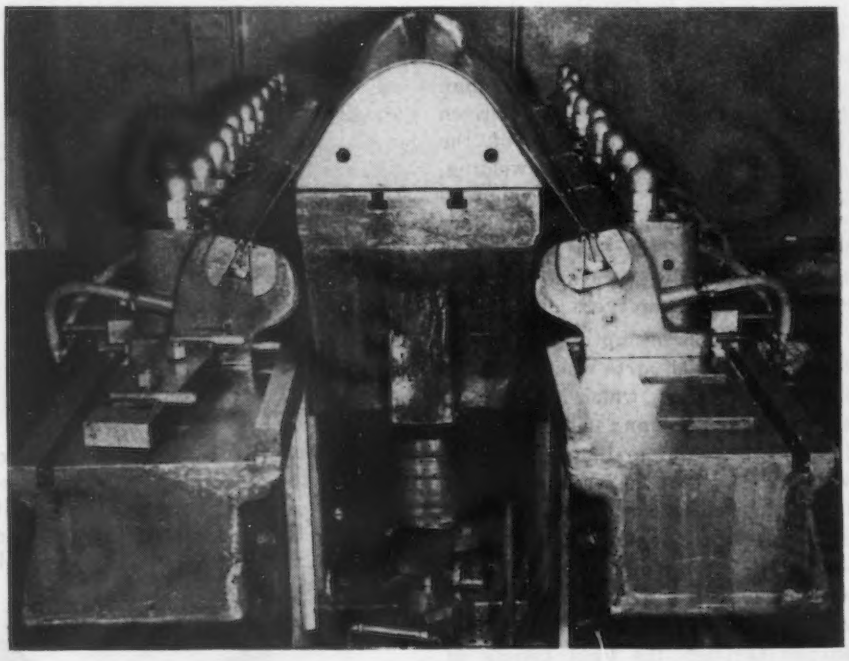

FIG. 2—The Erco stretching machine with its original jaws. This die has a relatively flat camber in the transverse plane.

Aircraft Parts . . .

. . . The belief that relatively flat skins cannot be stretch-formed unless the form is made in a relatively short arc, allowing for spring-back of the stretched parts to the shape wanted, has been nullified. The author describes a method of stretching with a die made to the exact shape and contour of the finished part, and includes much valuable data on physical properties of stretched material.

forming sheet supplied by Reynolds Metal Co., known as 24S-UT Pureclad, which means 24ST unstretched or unflattened. The percentage of elongation of this material is much higher than in fully flattened (stretcher leveled) sheets. Many parts are now being made from sheet in this special S-UT condition that formerly had to be made in the SW condition —thus eliminating re-heat-treat and storage in ice box as well as the danger of corrosion which will set in within a few hours on parts formed directly after heat-treat. Such parts have to be wiped off immediately after forming to prevent corrosion.

Recently, two dies of similar length were installed side by side in the stretching machine and it was found that with the extra elongation and better formability in the heat-treated, unstretched Pureclad sheet, the difference in crowns between the two dies could be overcome by stretching the low crown part just slightly more to allow the high crown part to stretch out completely. If the parts have only a slight contour, two parts may be stretched on one die by placing one sheet over the other; and with two dies four parts are completed with every stroke of the machine. This is also being done with parts made from SO material that are finished on drop hammer dies after being pre-stretched on starter dies.

Table I shows the average tensile strength and per cent elongation of 24S-UT Pureclad alloy sheet as compared with ordinary stretcher leveled 24ST. There is no doubt of the improved workability, particularly in the "as received" condition, in which

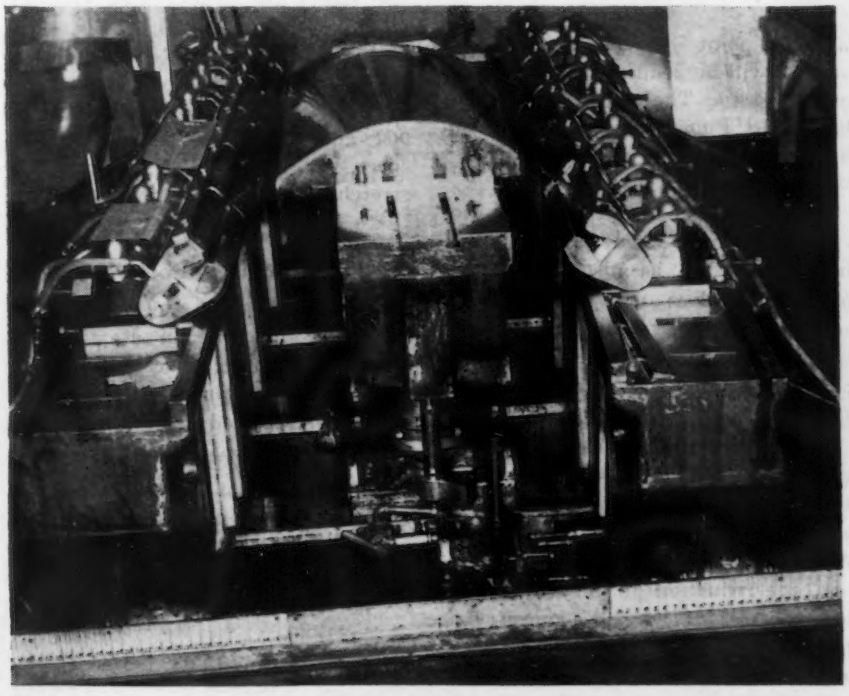

FIG. 3—The improved swivel jaws shown here make it possible to grip the sheet much nearer the dies, cutting down waste of material. The pull is always in the same direction as the contour at the edge of the dies. Graduated scales on the base, indicates position of the jaw beams. Travel of the ram is reduced by two air-operating rests.

TABLE I

Comparison of Tensile Strength and Elongation of Unstretched (Not Flattened) 24S-UT Aluminum Sheet with Standard Stretch Leveled (Flattened) 24-ST

No. of Tests Advg.	Direction of Test	Final Mill Operations on Sheet	Tensile Strength Lb. per Sq. In.	Yield Strength Lb. per Sq. In.	Per Cent Elongation	T.S. minus Y.S.	Advantage
			As Received				
3	With grain	Not flattened	63,170	42,000	18.2	21,170	6610
3	With grain	Flattened	66,030	51,470	15.3	14,560	
3	Cross grain	Not flattened	60,730	39,830	19.3	20,900	7540
3	Cross grain	Flattened	63,030	49,670	16.3	13,360	
			Sheet in the SW Condition (Re-Heat Treated but not Aged)				
3	With grain	Not flattened	50,400	20,200	23.5	30,200	870
3	With grain	Flattened	50,230	20,900	23.0	29,330	
3	Cross grain	Not flattened	48,270	19,100	23.8	29,170	640
3	Cross grain	Flattened	48,330	19,800	23.0	28,530	
			Sheet in the ST Condition (Re-Heat Treated and Fully Aged)				
3	With grain	Not Flattened	65,800	39,500	20.3	26,300	2170
3	With grain	Flattened	65,630	41,400	19.0	24,230	
3	Cross grain	Not flattened	63,830	38,530	20.7	25,300	1330
3	Cross grain	Flattened	63,600	39,630	19.7	23,970	

case the elongation in regular flattened sheet varies from 15 to 16½ per cent compared with 18 to 20 per cent for the new material. The difference is not so marked for the re-heat-treated and fully aged material and the material in the "green" state (re-heat-treated but not aged). In the table, the advantage between unflattened and flattened sheets listed in the extreme right column represents the increased working stress range available with sheets received from the mill in the unstretched condition. It should be remembered that the plastic working range available is bounded by the yield point of the material at the low end of the scale and the ultimate strength at the high end. The wider this range, the better is the forming quality of the material. That is why tough, resilient materials with a yield point near the ultimate strength are so difficult to form.

Fig. 4 shows a skin made from the regular 24ST. Note figures showing material stretch and compare with figures on Fig. 5, showing the same skin stretched on the same die, but of S-UT material.

Reduction in Thickness

It is important to know how much the thickness of material is reduced by this method of stretch forming. There is some reduction of thickness and it can best be determined by measuring a stretched part. In most cases a reduction of 3 to 5 per cent is shown on parts that can be stretched of ST material. This means that parts made of 0.032 in. material at the point of the most severe stretch will be reduced to a thickness of 0.0304 in. The reduction is much less if S-UT material is used and can hardly be measured unless the stretch is at least 4 per cent.

The grain structure in S-UT material seems to be somewhat finer than in standard ST, because the orange-peel effect does not appear after severe forming. Thus the better formability of S-UT material can be partially attributed to its finer grain structure.

It has been found that the reduction in thickness is about 40 per cent of the elongation required to form the part. By this is meant, if a part is stretched with a 12 per cent elongation, the reduction of the material is 40 per cent of 12, or 4.8 per cent, the resulting thickness being 95.2 per cent. For example, 95.2 per cent of 0.040 in. thickness is 0.0381 in.

In conformance with Poissens ratio, the material contracts spontaneously opposite to the direction of the stretching, thereby minimizing the reduction in thickness. This may only be taken into consideration if parts to be formed are about 24 in. wide or less. On wider parts the contraction takes place only along the edge of the part, and this in all cases is very helpful in preventing the parts from breaking.

Figs. 6 and 7 illustrate a part stretched in the SW condition (quenched but not aged). This part has been stretched to its limits and could never be made of fully heat-treated and aged ST material. The stretch ranges from 3.13 to 13.53 per cent. Again the reduction and stretch are found to be extreme between the jaws and the die. Tests have shown that a part made of 0.040 in. SO material, stretched in the SW condition with a stretch of 13.5 per cent reduces in thickness to 0.0378 in. or 5.4 per cent.

There is no safety margin in such severe stretch operations and they cannot be recommended because of the loss in material; if only one piece in ten is lost, it generally represents one-half of a sheet. In many cases going to the next heavier gage material is the only possible recommendation and this is frequently rejected by the engineering department because of the additional weight.

Stretch forming parts in the SW condition improves the physical properties of the material to a point near the values for heat-treated and cold worked SRT material. The tensile strength of the latter is 66,000 lb. per sq. in. and the yield strength 50,000 lb. per sq. in. as compared with 62,000 and 41,000 lb. per sq. in., respectively, for 24S-UT material. The stretch, however, should not exceed 10 to 12 per cent.

A Stainless Steel Job

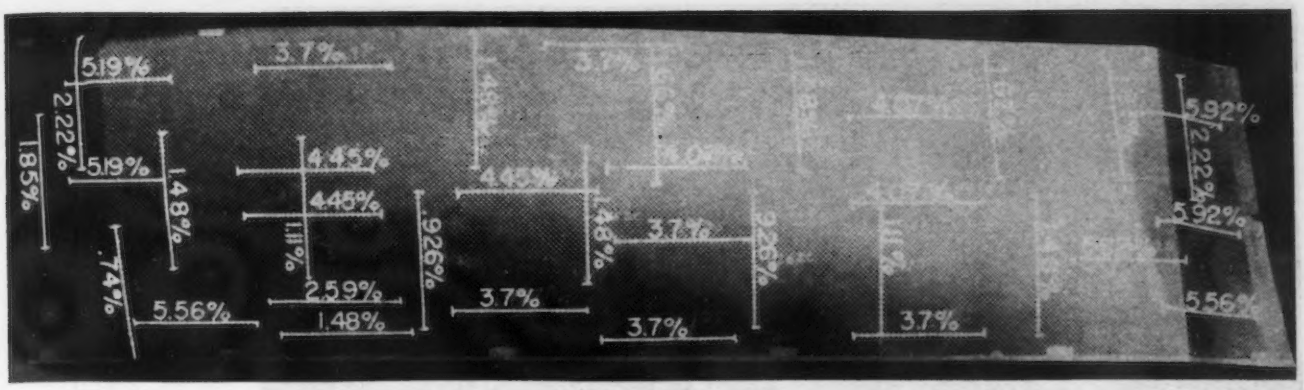
In one instance, the use of the stretching machine in starting the parts has been incorporated in a new method of forming parts for the stainless steel fixed cowl. This method

TABLE II

Average Tensile Strength and Elongation of Specimens of Fully Aged 24S-UT Pureclad Sheets After Stretching in Erco Press

Sheet No.	Tensile Strength Lb. per Sq. In.	Elongation in 2 In. Per Cent
	Specimens parallel to direction of rolling	
1	60,600	12.8
2	62,800	13.3
	Specimens perpendicular to direction of rolling and parallel to direction of stretching	
1	59,100	14.3
2	58,900	12.2
	Specimens paralleled to direction of "stretcher strains"	
1	57,800	11.0
2	58,900	12.5
	Specimens perpendicular to direction of "stretcher strains"	
1	58,100	11.0
2	59,200	14.0
(Required AN-A-13 specification:	56,000	15.0)

Direction of stretcher strains are at an angle of 60 deg. with the direction of rolling; direction of stretching is perpendicular to direction of rolling.



saves considerable material and eliminates the use of rubber, formerly needed in the drop hammer.

The old method began with a drop hammer starter die in which the parts were started one at a time, using considerable rubber and necessitating five or six hits per part. The excess material was then trimmed and the parts then hit in the drop hammer finish die. More often than not the parts had to be smoothed by the planishing hammers and re-hit before being sent out. The drop hammer starter die required constant re-work and replacement of punches due to the necessary rough usage.

The new method involves the use of a single stretching machine die which performs the starting operation on four parts at a time in about 1 min. This piece is then sheared into four pieces and finished in the same drop hammer finish die as formerly used, but with this new method no smoothing operations are required because the parts finish perfectly.

A comparison of the time required

The new part is shown in Fig. 8.

TABLE III

Stretch in 1 In. During Forming as Determined by a Grid on 24ST 0.040 In. Pureclad Sheet, Formed in the Non-Aged Condition after Heat Treatment (see Fig 10.)

Tensile Bar No.		Variation over Gage Length of Tensile Bar Per Cent	Average Stretch Per Cent in 1 In.
1		1.5–3.0	2.3
3		3.5–5.0	4.3
5		5.0–5.5	5.3
7	Specimen	3.0–4.0	3.5
9	Parallel to	3.0	3.0
11	Direction of	3.5–5.0	4.3
13	Stretching	6.5–7.0	6.8
15		3.0–3.5	3.3
17		4.5–5.0	4.8
19		5.0–5.5	5.3
2		1.5–3.0	2.3
4		4.0–5.0	4.5
6		5.0	5.0
8	Specimen	3.5–4.5	4.0
10	Perpendicular	4.5–5.0	4.8
14	to Direction	5.0–6.5	5.8
16	of Stretching	4.5–6.0	5.3
18		5.5–6.0	5.8

No stretch was found perpendicular to the direction of stretching. Any compression of the material was within the limits of accuracy of the grid and thus could not be measured.

The same production method is followed on the new parts which are now made from SO clad material except that the heat-treat operation had to be added before the drop hammer operation.

The nacelle door outer skins is the first complete unit to be transferred completely and successfully to the stretching machine. The original method of making these parts consisted of first forming in the drop hammer out of 24SO material. The parts were then trimmed and heat-treated. The warpage caused by heat treating was perhaps the greatest obstacle to be overcome, because the only way possible to iron out distortions was by use of power hammers which takes considerable time. Even after fitting each individual part to a form they were not as satisfactory as when formed on the stretching machine. First, the stretching machine eliminates completely the need for heat-treatment because 24ST material is used, thereby eliminating power hammer work. Second, the stretching machine uses merely a fraction of the time taken by the drop hammers in forming. For instance, in less than two shifts (18 hr.), 500 outer skins were formed, including trimming and setup time for two setups. Third, the parts fit much better and are all identical.

A comparative time table of the old and new methods for forming 24S material is shown below:

Old Method (24SO)

	Minutes
Drop hammer	5
Trim	2
Heat treat	3
Power hammer	20
Total	30

New Method (24ST)

	Minutes
Erco stretch press	1
Trim	0.5
Total	1.5

Some results of specific stretch forming tests, all of which show that the elongation is reduced by the stretching operation are given below.

Specimens were taken from a part pre-formed in the SO condition and finished in the SW condition (Fig. 9). The test revealed that this method cannot be recommended. Note that tensile specimen 2 is taken where the part has been most severely stretched. At this point the break has started because of the stretch applied to this area in the SO condition. The tensile stretch here is only 47,000 lb. per sq. in. Specimens 9, 11 and 12 show a tensile stretch of 63,000 to 63,900 lb. per sq. in., which is an improvement of 1900 lb. over standard 24ST clad material. This verifies the statement that physical properties are improved if a normal stretch is applied after heat-treat, as was done in the area where specimens 9, 11 and 12 have been removed.

This particular part is now manufactured in 24S-UT clad material with one re-heat-treat operation ap-

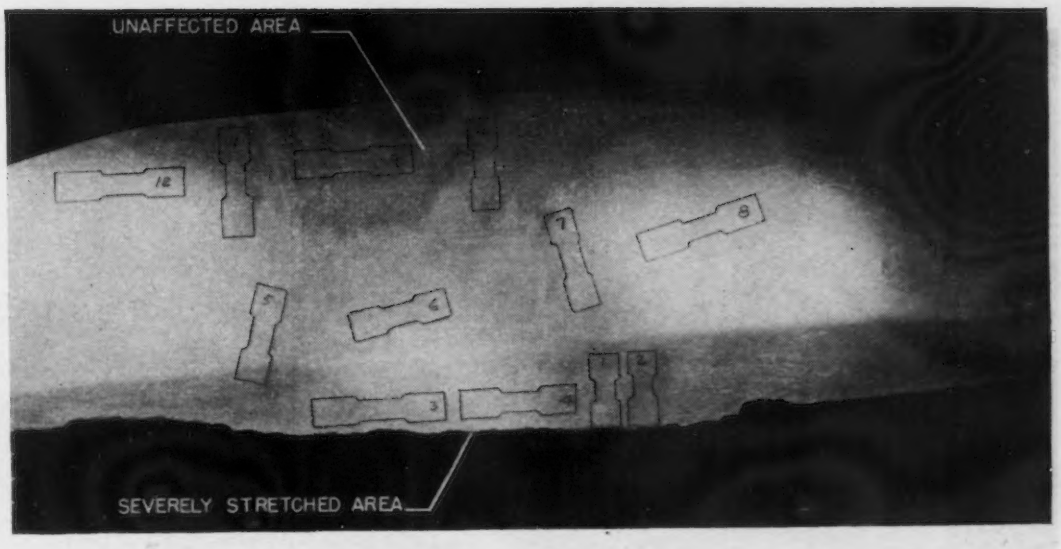

FIG. 9 — Skin preformed in SO condition and finished in SW condition from which the indicated specimens were taken. The break has started where the part has been most severely stretched (specimen 2), because of the stretch applied here in the SO condition. Data on the tensile test coupons shown in the photograph are tabulated below:

Specimen Number	Direction	Dimensions, Inches	Area, Sq. In.	Load, Lb.	Tensile Strength, P. S. I.	Elongation, in 1 In. Per Cent
1	T*	.037 x .393	.0145	835	57,600	5
2	T	.038 x .392	.0149	700	47,000	5
3	L	.037 x .497	.0184	1040	56,500	9
4	L	.038 x .501	.0191	1050	55,200	8
5	T	.038 x .500	.0190	960	50,500	5
6	L	.038 x .499	.0190	1100	58,050	15
7	T	.039 x .500	.0195	1040	53,300	5
8	L	.038 x .500	.0190	1085	57,200	12
9	L	.040 x .500	.0200	1260	63,000	18
10	T	.039 x .499	.0195	1200	61,700	12
11	T	.039 x .501	.0196	1240	63,500	19
12	L	.039 x .501	.0196	1250	63,900	15

*—T-Specimen taken transversely to the axis of the "stretcher-strain".
L—Specimen taken longitudinally with the axis of the "stretcher-strain".

plied before stretching, which was found to be the only solution to this problem. The original SO material that had been subsequently heat treated has not the strength in the SW condition that the S-UT re-heat-treated material has. It is likely that the difference in grain structure also is a factor.

In a second test, the 24ST aluminum sheet submitted for examination had been partially formed in the SO condition; heat treated but not aged, and finish formed in the SW or "green" condition over a form block on the stretching machine. The sheet broke at the edge of the stretcher jaws. In the most severely worked portion of the submitted aluminum sheet, the thickness of the sheet was reduced 7.5 per cent, the ultimate tensile stretch reduced 8.7 per cent and the elongation of the material reduced 72.0 per cent, as compared with the corresponding physical properties for a slightly stretched portion of the sheet.

In a third test, samples of 24S-UT Pureclad material were cut from the severely stretched portion of the sheet between the stretched jaws and the form block. The material was formed in the SW condition and allowed to age at room temperature for four days before being tested. The severely stretched samples did not have the required elongation but did have the required minimum tensile strength of 56,000 lb. per sq. in. The relationship of tensile strength to direction of rolling to direction of stretch and to the direction of the stretcher strains is shown in Table II.

In a test to determine the physical properties of stretched 24S-UT and 24ST Pureclad sheets after they had been completely formed into the same part shape by the method of fabrication applicable to each type of material, the 24ST sheet was heat-treated and formed on the stretcher press in the SW condition and the part was allowed to age completely before testing; the 24S-UT sheet was formed on the stretcher press in the "as received" condition.

Both of the parts examined had satisfactory physical properties for the respective type of material from which they were formed. The 24S-UT sheet had an average of 9.0 per cent greater tensile strength and 22.5 per cent greater elongation in 2 in. than the 24ST sheet after fabrication.

An attempt was made to gain some knowledge of the amount and location

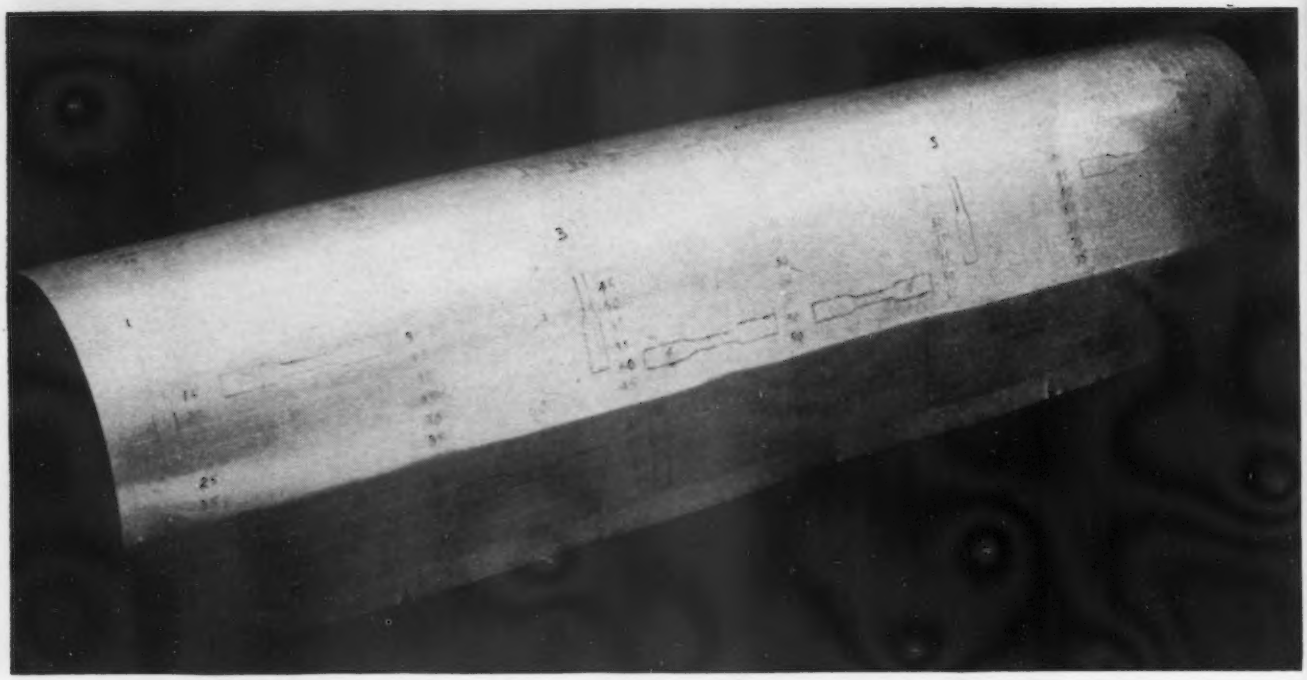

FIG. 10—Part formed from 24ST 0.040 in. Pureclad sheet in the SW or "green" condition (re-heat-treated but not aged). Before stretching in the Erco press, the part was marked with a 1-in. grid. Physical data on the tensile bars marked on the sheet are given in Table IV. The amount of elongation in the direction of stretching is given at inch intervals in tenths of a per cent (thus 15 equals 1.5 per cent). The stretch data are summarized in Table III.

of the stretch which took place during fabrication operation on the form stretcher. Because of the lack of facilities for placing a non-destructive grid on the parts to be tested, another sheet of 24ST Pureclad was marked with a grid by lightly scribing lines on it 1 in. apart. This sheet was then heat-treated and stretch formed in the green condition. The amount of stretch at various locations are shown in Fig. 10, and in Table III. The values give a general picture of the amount and location of the stretching. The accuracy of this method is limited by the accuracy of the grid. To obtain an estimate of the total amount of elongation the material was subjected to, the values determined on this sheet were added to the elongation of the respective tensile specimens (see Fig. 10) from similar locations to obtain the total elongation. The physical properties of these tensile coupons are tabulated in Table IV.

Stretch forming is surely the only expedient way to fabricate many parts, and this method should take its place alongside the deep-draw method, which should also be used more for the manufacturing of airplane parts.

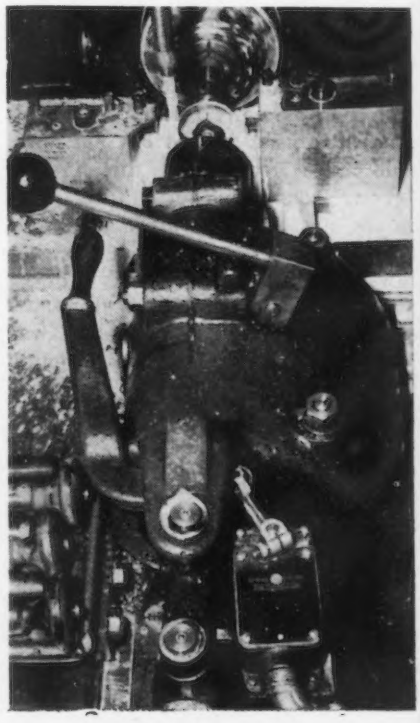
Stellite Faced Valve Machined with Carbides

MACHINING of Stellite and steel simultaneously with the same cutting tools on a mass production basis is being achieved by Thompson Aircraft Products Co., Euclid, Ohio, manufacturer of a large variety of precision aircraft engine parts. Carboloy cemented carbide tools are used to accomplish this.

The part is an alloy steel aircraft engine valve with Stellite applied to the o.d. of the head and seat. It is machined on a Sundstrand automatic stub lathe having a front and rear tool slide. The front slide carries a Carboloy turning tool while a Carboloy forming tool for finishing is mounted on the rear tool slide.

The valve is held on the stem end by means of a collet in the work spindle and supported at the head end by the tailstock center. The operator pulls in and locks the tailstock with a lever the movement of which also actuates a toggle switch mounted on the tailstock (see cut) which starts the spindle as well as the feed of the two slides. Feed is automatic and the machine stops when the cycle is completed.

The carbide turning tool makes its cut across both the steel and the Stellite surfaces at the same speed (80 ft. per min.). The instant the tool clears the work, the forming tool comes in for the finishing plunge cut. Excellent results are reported from this combined operation, both as to production and the quality of the surface finish, as well as tool life, considering the difficulties involved.



How to Use Triclorethylene Solvents

. . . Written by a shop man for shop men, this article describes solvent types of cleaning equipment, their use and maintenance. Proper utilization gives superior cleaning at less cost, with dangers inherent in handling this chemical reduced to a minimum.

o o o

By HERBERT H. HINES
Springfield, Vt.

o o o

VERY little has appeared in print about triclorethylene. In various forms it is being used by numerous plants in this country and Europe, by the army and navy. Yet in the plants where it is used very few foremen know what it is or how to handle it. The heads of departments know that it is better than the old soda kettle method of cleaning metal, have heard that it is dangerous to the health of the operator, that it is hard to keep operators on the job, but haven't read anything about it and know little authentic about it except what is seen casually as they go down the alley in the plant.

There are adequate, though generally antiquated, articles in chlorinated hydrocarbons in mechanical encyclopedias. Most of them are prewar and out of date. The writer's practical experience with it has been entirely during this war period. It came fast. New data have not been compiled. Comparative information, which is needed, has not been made public, or at least is not generally known. The chemistry of it is fairly common knowledge, but the average shop superintendent and certainly the usual operator is not a chemist.

There is a bewildering confusion in the medical profession as to whether it is toxic, causes heart trouble, or has any permanently pernicious effect upon those who use it. Operators disagree and shops vary as to opinions and decisions. Salesmen even compete in arguments for their elimination of disagreeable effects, and advertisements have begun to recognize that there is an argument to be met.

This article is not a chemical treatise or a medical examiner's report or an engineer's verdict. It is written by an operator who has had about two years' experience on degreasers and is now in charge of all such operations in a machine tool plant flying two well-won "E" pennants. It is written at the request of plant superintendents for simple information. The writer has had practical experience, has read everything he can get his hands on concerning the job, has pumped chemists, doctors, professors and salesmen for detailed information. He had six weeks' hospitalization which may have been caused by contacts with these solvents. His hands are burned with it. One doctor told him that he was doing a sacrificial patriotic service to industry to operate with it. He has seen many operators come and go. He has tried to do a good job with it. Perhaps the present governmental limitation of its sales by 30 per cent will force the industry to change the product or find a substitute. For the present the industry has triclorethylene to use. In a day laboring-man's language, what is it and how is it being used?

Like a good many of scientific necessities the first degreasers were used in Germany. They had to get a quicker and better cleaning job for materials that had gone to or through production lines. The Germans made the first triclorethylene to meet this demand. Every piece of steel, except a few of the higher grades, has to be covered with some sort of grease that will prevent rust. This has to be removed before assembly. The old method was to use a soda kettle or a pail of kerosene and a rag. It was too slow, inefficient and a considerable fire hazard. Chemists worked for years to find a quick boiling solvent that would cut grease and dry immediately. Chlorinated hydrocarbons had been used for various cleaning jobs, and dry cleaning plants had developed their use in many of these jobs.

The first use of triclorethylene in Germany was not highly successful. It did a good job on steel and the operators. It degreased both. Many operators died. The form of it developed in this country was a better product, purer and cleaner and less

dangerous. It was made non-inflammable by changing the flash point, and it was made safer. Individual companies, buying new trichlorethylene, added their own stabilizers and volatilizers. The result, sold under various trade names, is a solvent that boils twenty-four degrees quicker than water, is volatile (has the same chemical formula in its vapor or distilled form), is five and one-half times heavier than air, so normally stays down in the machine. It cuts most grease instantly, cleans adequately, and when properly handled causes no more trouble than is found in any other part of the factory.

About 1935 American companies that had been working on this problem for about 20 years began to produce machines to use this new solvent. Three types became common: immersion, vapor and spray. These today are found in various combinations, and in sizes varying from bench models to huge conveyors. These machines, with heating attachments, have compartments large enough to take baskets of work and yet small enough so as not to crowd the building. Each machine is a still, working over its own solvent for a clean dip, bath or spray.

In the vapor type machine the solvent is heated by either electric coils or steam. Steam is more easily controlled and cheaper if available the year around. The solvent boils at 86.7 deg. C., or 188.6 deg. F. Vapor from it rises in the tank. About two-thirds of the way up the tank are water coils or a water-jacket (a patented feature of one company.) The height of the vapor line is regulated by thermostats and the temperature of the water. When the vapor strikes the cool coils or water jacket it condenses and is returned eventually to the bottom of the tank. The baskets of work are dipped into the vapor. This clean vapor is from the solvent only. Pieces have no contact with anything else. The baskets may be small and hand-dipped, or they may be large and operated with an electric hoist. A spray hose may facilitate the work.

In the immersion type there are usually two dips after a vapor bath, one to cut the grease and the other for a final rinse. The immersion type is faster, as most pieces require only a 30 sec. dip and a quick rinse. It also penetrates holes that would be untouched with a spray. It is better for smaller parts.

The cost of degreasing has been cut in half in recent years. When original cost is compared with the cost of the old soda kettle it may seem a luxury. But when the tremendous amount of work that these machines will do in a day is taken into account, and also the money and time involved in the old methods of hand cleaning, the saving is evident. Men on the assembly floor who used to hand-clean their own work in a pail almost doubled their assembled output with machine cleaning.

One expensive high grade steel piece valued at $275 was protected with a special grease. It required 20 min. and a high priced grease remover to clean it. The machine did 20 pieces in 20 min. and did a more thorough job. Machines are built to take anything from minute parts to airplane wings, even with paint-dip and drying attachments. Companies are sold machines adapted to their jobs, and each machine is sized for certain weight limits per hour. This is not an argument for buying degreasers, for the government has recently said that there are enough in plants and forbids the companies manufacturing any more at present. This is just an explanation to aid in understanding what we have in operation now.

Is It Dangerous?

Is trichlorethylene a dangerous solvent to use? Of course anything might be dangerous under certain conditions. Can it be handled so that there is no danger at all? Perhaps not enough information is available to answer this question fully now. Even doctors disagree. The 53-gal. drums that bring it to the shop have labels with a toxic warning. Perhaps if there was no warning operators would be less careful.

Some plant doctors would put it out of the building. Some medical books analyze the known ills that come from it and believe there is no permanently harmful effect. One girl drank some by mistake, was given olive oil, and went to a dance that night. Some men have developed a "narcotic craving" for it. It gives them a cheap drunk.

One doctor in a very recent report told of using it as an anesthetic to cure severe headaches. It cured the headache, but the patient died of ventricular fibullation. Several cases are known of deaths of operators of the conveyor type. They died of asphyxiation while within the machine working on repairs. It may have been the solvent that contracted the heart muscles until they acted singly instead of together and stopped the flow of blood. In one case the doctors believed the solvent harmed the heart so that the operator could not pass Army or Navy physical examinations. There was one case of acute kidney and bladder stoppage that most likely would never have happened if the operator had been working in a hay field. These can be multiplied in each plant.

Careful diagnosis has not always been made. A company will transfer an operator from a degreaser job if he says it hurts his feet or prevents sleep. The word of the operator is accepted without much medical opinion. It is, of course, no secret that many people do not like the smell of it and say so violently. This is taken into large type in some advertising. Some men are allergic to it and feel sick to their stomach when near it, much as some are if they smell too much paint. One man said it gave him a quinzy throat. Investigation said that he had been treated for such a throat condition years before. Yet the solvent may have aggravated an already unhealthy condition. Honest diagnosis is necessary and comparative information should be known.

Manufacturers, to be on the safe side, say it is toxic; therefore, it is wise to be careful. Companies do transfer operators from degreasing machines on complaint. Some give regular health examinations. They feel they must do it. Operators do get dizzy, and some do not like to work with it.

The trained operator knows what it is and how to handle it. Yet, in spite of caution, a gust of wind may blow the vapor at him and give him a dizzy, staggering, dopey feeling. His hands may be burned with it. He may splash it on his face or in this eyes. Usually a few minutes in the fresh air will clear the operator's head. He gets used to it, and when splashed by it generally will just stand still for a minute and let it evaporate. There is no after hurt. Most operators do not think that the effects from it are permanent. Even the one who had bladder trouble cleared it up in a few weeks. Like some other contacts, it may hit a weak spot. Some people, especially negroes, should not handle it at all.

The simple precautions are: Wear dry gloves, do not stand over the machine any more than is necessary, do not smoke over or near it, keep the vapor in the machine, and take time to dry off the work.

If machines are in proper condition and are properly used operators have very little trouble and learn to like their jobs as they become experts. Much of the bad odor attributed to it comes from burned oil. New smells usually require time to tolerate.

These solvents have high resistance to rust. They will clean even when dirty. They are fast and satisfactory when properly operated. The operator who is trained by his foreman, and experienced, knows that the heat of the vapor almost equals the heat of the boiling liquid. Therefore, he is careful. Hold a clean, dry hook in the vapor inside a degreaser and watch the distilled solvent run from it. Baskets must be raised or lowered slowly, about 9 to 12 ft. per min. Loads must be kept small. It saves time in bringing up the vapor level, and does not force the vapor out of the machine into the room. This is one of the simplest and most difficult tricks to teach new operators. If they take a little more time they save time. It means protection to them and less complaints from other machine operators in the same bay.

The same lesson applies to smoking. There is no danger as regards the solvent, as most of them have been made non-inflammable. A dip tank, which usually is a part of the operator's equipment, is filled with a greasy oil with a paraffin base which dries quickly and keeps pieces clean and rust free for the stockroom. This may be inflammable and necessitate special care. The attempts to find a very thin dip that is satisfactory, quick-drying, and would require no further degreasing before assembly is still one of the trade necessities and an unsolved goal of the oil companies.

To avoid all fire hazards and prevent harm to the operator, the customary warning is "No smoking in this restricted area." Usually the harm is not to the solvent, but to the operator. The fumes of the vapor combine with nicotine and produce a third acid which is harmful to the throat and lungs.

Most degreasing machines have been placed in factories as afterthoughts. Some corner that was unused, or some handy open space along the side of an alley has been cleared out and the degreaser installed. It may be that work benches or other machines are too near. It may be a draughty place where air currents will drive the vapor out into the room. Released vapor, being heavier than air, settles to the floor. A top ventilator is insufficient. Some factories put a case around the degreaser which will take off all fumes. Some have an especially air-conditioned room. This could be built easily even into older buildings. If the machine is sunk into a pit there must be a special floor blower. Home-made blowers to carry off the vapors have not been highly satisfactory. It is a problem for the air conditioner, and since the average older factory hasn't taken this problem seriously, the situation for a degreasing operator is generally no worse than for the operator of other machines. Something like the electric precipitron should be in the plans for the future. It is an investment in economy as well as health, and ought to be compulsory.

Much of the trouble with degreasers has come from cheap, poorly paid help, untrained in caution, operating a machine they do not understand. Some of the trouble has been deliberate, done to get a transfer, or to get the machine moved to another part of the factory building. Most of this trouble can be prevented.

Gas masks may be necessary in rare instances. They are valuless unless they cover the eyes as well as the nose and throat. Most operators never wear them.

Some plants do not allow women operators on degreasing machines. In their monthly periods these solvents may affect some women much as paint does to a pregnant woman. With proper replacements some factories are operating as many as three-fourths of their degreasers with women. The usual operator has to do a great deal of lifting, in spite of the electric hoist, so that outside of departments cleaning small work such as die parts, a strong able-bodied man is usually required.

Care and Caution

Degreasing problems came into factories so suddenly that little was done at first to unify the work or correct mistakes. About 1940 plant superintendents, at some machine tool show, saw a degreaser in operation for the first time and said that that was what they needed in their plant. It was ordered, placed in an unused corner, and put under the direction of a foreman who did not know how to operate it. Other degreasers were later added to the plant, each placed under the supervision of a different department. The results depended up the luck of finding a good operator who would keep his machine in good condition and do his work reliably. He cleaned it when he thought it necessary, or when he had a slack hour.

This turned into confusion. No one was responsible. Machines were constantly breaking down. Once in a while one would become short-circuited and the oil in the tank catch afire. Neighboring machinists got up a petition to have the degreasers removed from the plant. Service men from the manufacturing company did all they could. It was a headache to the master mechanic. The consumption of a solvent was so large that the factory was about ready to go back to soda kettles.

This bad situation was soon cured. In one plant it came gradually. One operator had been working for about a year on an immersion type machine. He had complete charge of it. It worked well and was never out of repair. When something went wrong he fixed it himself. There was no one in the plant who knew anything about degreasers beyond casual observation. Being interested in his work he determined to be the plant authority on dgreasers. He went to two engineering schools and talked with professors. He read every article or booklet on the subject he could lay his hands on. He pumped salesmen, service men, plumbers, electricians and chemists for information. The result was that when another degreaser in the plant needed special attention he would be sent to repair it. Finally a new arrangement was set up putting him in charge of all degreasing machines night and day. He saw that all machines were running satisfactorily at all times and that work was done as it should be. Soon the headaches disappeared, neighboring operators stopped complaining, and plant officials forgot they had any degreasers.

This is the easiest solution. Put a trained operator in charge of all degreasing machines. Give him opportunity to learn the routine and needs of each machine. Let him supervise the cleaning (which should be done by the same man each week), have the right to shut down any machine he requires, and keep all machines in running order. Then there will be few troubles or complaints.

There are five main responsibilities of the chief operator. The first is toward the men under him. Good operators are absolutely essential. They must be broken in by the chief operator, taught to know their machines, to do satisfactory work and guard their own safety. They must know the nature of the solvent. They must be quick to recognize anything wrong with the machine. They must cooperate with the foremen from whom they get their work and to whom they send it. They must be "good housekeepers." They must be provided with plenty of leather gloves, hooks, baskets and other necessities.

At first operators were selected from older men who were tired of sweeping floors. It was enough to show them how to operate the hoist and how to put the basket into the vapor and take it out. Now it is rec-

ognized that the operator should be as strong, alert and intelligent as any other machinist. It takes as long to be a good operator on a degreaser as to break in a raw workman on a turret or milling machine. He should be given good equipment. One bad case of rust was traced back to dirty gloves. He should be encouraged to handle his work carefully. Gear teeth are easily marred, and scratches may spoil precision, particularly where high accuracy is demanded.

The job of the operator of a degreasing machine should be recognized as essential and respectable. It ought to be well paid, so that the operator will have an incentive to take greater interest in his work. Sometimes he needs help. Frequently he needs special encouragement. The chief operator can absorb his headaches and give him the cooperation he needs.

His second responsibility is the degreasing machine. He must know each one. He must know how to operate them and what is required of them. He must see that they are cleaned so regularly that they are always free from dirt, rust and water. Some need to be cleaned every two or three days and some once a week. It must be done on schedule. If the machine accumulates too much acid a soda bath may be necessary. He must know what to do and be willing to get dirty.

The machine must be repaired at necessity promptly. It must be kept filled with solvent to a proper level. The thermostats must be properly set and regulated. There must be an adjustment of the water used through the coils or jackets to the humidity in the air. Typical repairs are to hoists, wiring, coils (which burn out like light bulbs), pumps, air hose, hooks, baskets, faucets or gages. A rusty machine may be rezinced.

The third responsibility is for cleaning the machine. This must be done regularly, as often as accumulated sludge demands. Most solvents will still clean when dirty. But it is harder on the operator and more liable to start rust. In cleaning, the solvent is distilled in the machine as far down as the coils permit. If the residue is taken out with an electric pump it will cause less trouble. The sludge contains solvent plus the oil from cleaned material. The still pays for itself in a short time in solvent saved. A further argument for a still is that the solvent saved will titrate higher than the original solvent, and is a life-saver in rust prevention—one of the other headaches in all steel plants. The still is simple to operate. In fact a small sized immersion type degreaser answers the purpose. The boiling point should not exceed 260 deg. F. And, do not try to pour cold sludge into boiling liquid.

The coils must be taken out of the lower door so that all carbon can be removed from them and the floor of the degreaser thoroughly cleaned. Sometimes a vacuum pump helps. Generally it is a job for a broom and a hoe. Proper gaskets, well lubricated, must be replaced to avoid leaks, and the machine put back into working condition. This operation may require from 1½ to 5 hr. The immersion type takes longer. The work may be speeded up by pumping all solvent from the machines and doing all distilling at the still. The most important item is to have a regular calendar for cleaning and a constant check to see that it is done right.

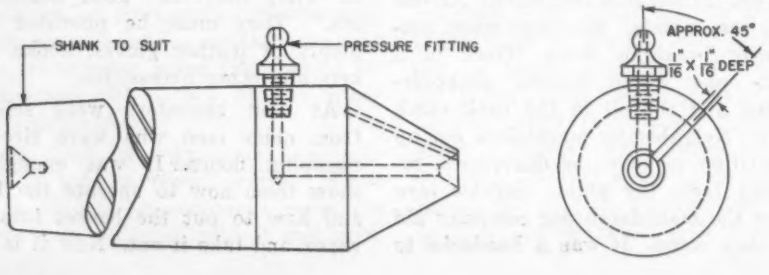
A fourth responsibility is the avoiding of rust. What is its cause? Where does hydrochloric acid come from? How did the water get into the machine? Humidity is most unwelcomed in a steel plant. There are two months in each year when it is especially troublesome. Some men's hands are so oily that a piece of steel they touch at night will be rusty the next day. Pans of machined parts may rust in a day. The water in the air, the moisture from pipes, a leaky water pipe, rain through a window, any of a number of things may cause corrosion. A near-by foundry sends off acid into the air that eats the copper roofing. It is in the air. A strange acid may be found to come from a woolen mill far up-stream. The causes have to be studied. It is less expensive to have rust prevention than rust removal.

If there is rust in a degreaser it may spread to the work it is supposed to clean. One machine rusted from excessive water. Service men could not find the leak. They washed it out completely with soda water. It still contaminated the work that went through it. Finally a leak in a water pipe was discovered, corrected and the trouble stopped. Pipes drip water on humid days. Moisture accumulates. The amount of water run through the coils must then be cut down, and the water in the machine, not otherwise taken out by the water separator, removed. A chamois skin dipper works easily. Machines must be neutralized if an acid condition exists. Some solvents do not take aluminum or magnesium, and acid may result. The easiest and surest test for rust resistance is to titrate samples of distilled solvent from each machine. If this is done regularly once a week, or on suspicion, there is positive evidence as to the presence or absence of acid. If the score of each machine is kept for a few months, and the average per cent of rust resistance known, there is no guesswork as to how the machine is running. If the per cent is low it may be built up with fresh solvent or with "super solvent" from the still.

The fifth responsibility is for the consumption of solvents. If this is not watched the whole job might be considered a luxury. In one shop the average of 3 gal. per day per machine for the immersion type and 5 gal. for the vapor type were established. These were medium sized machines. It was reduced 20 per cent by using the still and almost 10 per cent by careful supervision.

Lubricated Lathe Center

A SPECIAL lubricated lathe center devised at General Electric's Pittsfield Works prevents shaft centers from "picking up" when machining heavy shafts. Lubricant is introduced into the hole in the center of the shaft by a pressure gun through a fitting on the shank of the lathe center. It is forced into the shaft center and when full it is indicated by exuding along a 1/16 x 1/16 in. groove on the outside of the lathe center. As the shaft turns, the lubricant is wiped against the shaft center. The groove is positioned where there is low pressure between the machine center and the shaft center. This obtains the best possible adhesion of the lubricant to the shaft center.



With this arrangement, the shaft center can be lubricated while a cut is being taken.

Speeding Heat Treatment of Aluminum Alloys

By S. G. ANDREWS
Process Engineer, Lockheed Aircraft Corp. (Plant A, formerly Vega)

SOAKING time for heat treatment of clad aluminum alloys which is longer than necessary reduces the productive capacity of the ovens and causes diffusion of the copper into the aluminum alclad, and surface blisters, Tests recently undertaken at Vega Aircraft Corp. indicate that the minimum soaking time required to obtain satisfactory results for 24SO 0.125 gage aluminum alloy is 30 min. for 24SO, 0.051 gage aluminum alloy it is 15 min.

The furnaces must be so controlled that the temperature does not vary ± 4 deg. F. from set heat treating temperature of 920 deg. F. A Knapp "Quick-Quench" vertical overhead type furnace, with one thermostat at top is used. With a different type of furnace or with three thermostats, some of the following statements would not apply: Parts must be loaded on heat treating racks to allow free circulation of air about all parts. There should be no overlapping of edges on parts. To avoid the possibility of mechanical disorder in the furnace, the specified minimum soaking time should be 3 to 5 min. above absolute minimum.

By using the soaking time specified in Chart I, the different gages of material can be heat treated accordingly. In comparison with previous specifications, by using this specified soaking time, 10 to 15 min. per load can be saved, which in a 24-hr. run will give five to six additional production hours. It should be pointed out that the AN-QQ-H-186 soaking times are wide in range and that the minimums shown are broken down for gages and are applicable because proper control is exercised to see that the loadings consist of only one gage of material as far as is practicable.

The 0.125 in. samples heat treated for 29 min. and 40 min. all met physical requirements of Air Corp specification 11067-A, and corrosion resistance of specification AN-QQ-H-186. The 0.040 in. and 0.051 in. samples heat treated for 15 min. at 920 deg. F. all met requirements of Air Corp specification 11067-A except one sample which was low in yield and two which were low in elongation. All specimens met corrosion test of specification AN-QQ-H-186. The 0.051 in. samples heat treated for 20 min. at 920 deg. F. all met physical requirements of Air Corp. specification 11067-A, except two specimens which were low in yield strength. In all cases, the low yield samples were found on the very bottom of heat treating racks where most unusual conditions would exist.

The results of shorter soaking time are as uniform as those of longer soaking time as taken on previous heat treat checks. The variance in low yields or elongation occur in both cases.

TABLE I

Minimum Soaking Times Required for Heat Treatment of Clad Aluminum Alloys

Specification AN-QQ-H-186

Gage of Material In.	Soaking Time, Min.
0.20 and less	20
0.020 to 0.032	25
0.032 to 0.063	30
0.063 to 0.125	45
0.125 to 0.250	60
0.250 to 0.500	90

Vega Specification 521

Gage of Material, In.	Soaking Time, Min. Permissible Range	Desired Minimums
0.020	5 to 15	10
0.025	10 to 20	10
0.032	10 to 20	15
0.040	20 to 30	20
0.051	20 to 30	25
0.064	20 to 30	25
0.072	30 to 40	30
0.081	30 to 40	30
0.091	30 to 40	35
0.102	30 to 40	35
0.125	30 to 40	40
0.156	40 to 50	45
0.250	50 to 60	60
0.500	70 to 90	80

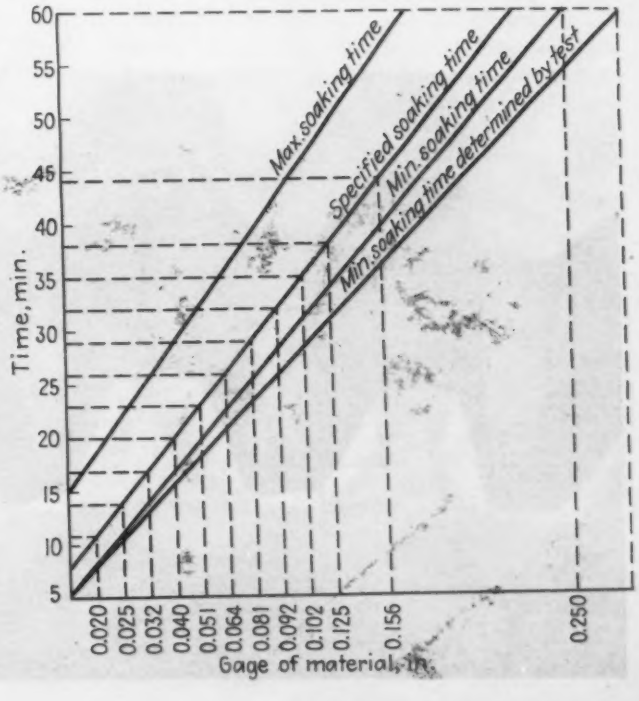


FIG. 1 — Soaking time for heat treating 24S clad aluminum alloys.

Flame Hardening Aircraft Gears

FABRICATION of gears for retractable landing devices on Army P-39 Airacobras, built by the Bell Aircraft Corp., Buffalo, N. Y., includes a flame-hardening process on gear teeth that permits close control of gear teeth hardness and better quality of the finished product. A special Gleason surface hardening machine permits almost automatic treatment and makes possible the acquirement of desired surface hardness characteristics in the individual teeth while at the same time maintaining a desirable softness in the teeth cores.

The parts treated is a gear sector that moves the leading wheels into desired position, being driven from an auxiliary power system in the plane. The arrangement also permits operation by a hand crank in event the landing mechanism is damaged. This automatic landing mechanism must respond under the varied climatic conditions prevailing on the scattered fields of war all over the world. Also, the tremendous impact of the plane in striking the earth at high speeds makes extreme care essential in fabricating and assembling, so that sufficient strength is built into it.

The gear sector used is machined from a chromium-molydenum steel forging. It is heat treated to a tensile strength of 150,000 lb. per sq. in., and the gear teeth are hobbed on standard hobbing machines. The flame hardening operation that follows to harden the gear teeth surfaces must be carefully controlled to assure that the bearing surfaces acquire correct hardness but do not alter too much the soft core in the center of each tooth and thus alter the tensile strength of the part. Bell uses a No. 1 Gleason surface hardening machine with two oxy-acetylene flame jets. The jets are adjusted so that the two flames, as they are moved by the carriage, strike the teeth simultaneously on either side. The travel speed of the burners over the part can be adjusted, depending upon the desired hardness of the gear tooth surface. An experienced operator can accurately determine by the coloring of the tooth under heat when the correct metal temperature is reached, a dark cherry red being most desirable for this operation. The heating temperature is about 1500 deg. F.

If the teeth were hardened successively on the gear, overheating would occur at the core of the teeth. For this reason, the jets traverse the first tooth, hardening it, then stop clear of the forging while the machine automatically indexes the third tooth into position for hardening. The odd numbered teeth are hardened in the first rotation. The gear is then reset, and moved through another rotation which brings the even numbered teeth into position for processing. After a tooth has been hardened, the jets stop their travel momentarily while the machine turns a succeeding tooth into position. The back travel of the jets is rapid over the new tooth,

o o o

AFTER flame hardening, the gear teeth are examined for hardness depth. The teeth ends are filed lightly and acid hypo is applied. The hardened area remains bright, but the soft core area is dulled by the hypo action, clearly indicating the depth of hardness penetration.

o o o

performing a slight preheating operation. A soluble oil is used in the water coolant to prevent rust. This coolant is directed well below the base of the teeth and used only to dissipate and carry away the heat that is conducted into the gear base.

To insure proper quality control, each gear hardened is examined to determine exactly the area and depth of hardness. The ends of the sample teeth are filed clean and painted with acid hypo, common in a photographic laboratory. Under these conditions the hardened area is visible in cross-section, standing out as a shiny surface. The soft core area is contrastingly dull.

After heat treat the chromium-molybdenum steel forgings register a hardness of about 33 Rockwell C. After flame hardening, the teeth surface areas register a minimum of 60 Rockwell C. Final machining completes the gear and it is ready for assembly.

o o o

THE bearing surfaces of the teeth of landing gear sectors for the P-39 Bell Airacobra are flame hardened. Following a quick preheating pass of the flame jets over the surfaces, they are heated to about 1500 deg. F., and air cooled. The coolant jets shown play on the web structure to help dissipate conducted heat.

New Polyvinyl Resins Developed

TWO unique polyvinyl resins have recently been developed. They are identified as Geon No. 202 and 203 and are entirely new vinyl chloride, vinylidene chloride copolymers, much different from any of the others previously developed.

This new resin series was created to meet the need for polyvinyls which combine increased solubility and thermoplasticity with exceptional stability, chemical resistance and wide useful temperature range. Their resistance to hydrolysis by boiling water or even hot alkali is outstanding in the field of vinyl chloride copolymers. The No. 202 is a general-purpose copolymer, more soluble and thermoplastic than either of the No. 100 resins, while these characteristics are still further stepped up by the No. 203.

The new resins can be processed easily on existing equipment, and will expand the field served by this class of plastic materials. These resins can be used in coating of fabrics, paper, foil and other materials, insulation of wire, manufacture of film for packaging, and the manufacture of extruded and molded products. Purchases of any of the resins are subject to allocation by the War Production Board, although reasonable quantities are available for experimental purposes.

These resins, when compounded with other materials can be processed in many ways, including injection and compression molding, extruding, calendering, solution coating and film coating. Compositions varying from the rigid thermoplastic to a very soft jelly can be obtained by modifying the resins with other compounding materials. Each composition exhibits to a high degree the many desirable characteristics of the base resin used.

In addition to furnishing the resins in powder form with the compounding done by the purchaser, this material can be secured in ready-to-use form, either as granules or sheet. Tailor-made formulations can be supplied for special purposes. It is pointed out, however, that because these materials can be varied so widely in useful properties, it is to the advantage of the user to consult the manufacturer in choosing a compound formulated to fit a specific need. These resins have been developed by the Chemical Division of the B. F. Goodrich Co., Akron, Ohio.

Properties of the four Geon resins are

Geon No.	Specific Gravity	Average Acetone Extract	Average Specific Viscosity*	Recommended Solids in M. E. K.**		Plasticizer Index***
				at 20 deg. C.	at 70 deg. C.	
		Per Cent		Per Cent	Per Cent	
101	1.41	15	0.55	4.5	12	43
102	1.41	14	0.59	4.5	12	43
202	1.43	48	0.40	8	17	34
203	1.44	56	0.36	14	25	31

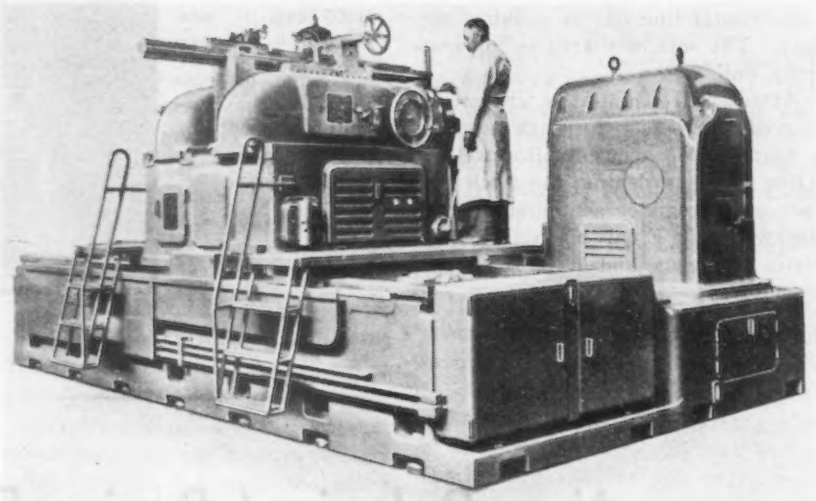
* At 20 deg. C. of 0.4 per cent solution in nitrobenzene
** Methyl ethyl ketone
*** Weight of dioctyl phthalate per 100 weights resin to give comparable hardness at room temperature.

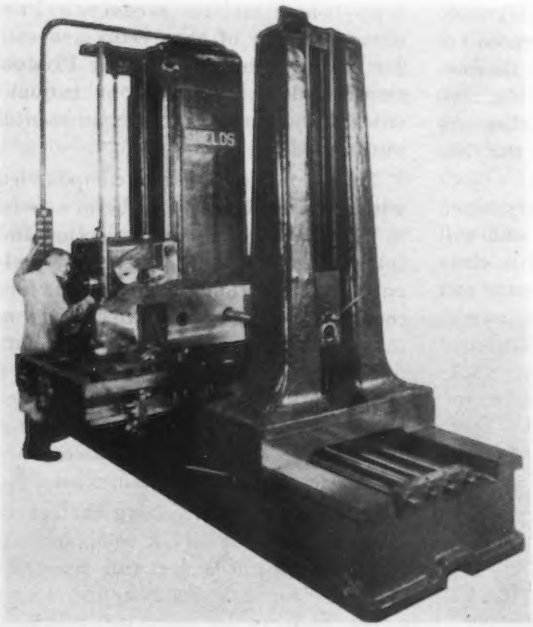
New Equipment . . .

Machine Tools

. . . Recent developments in boring mills, gear shavers, marking machines, milling machines and various kinds of sawing machines are described and illustrated in the following pages.

ON the horizontal boring mill developed by *Shields Mfg. Co.*, 3809 Twenty-fourth Street, Long Island City, N. Y., infinite variations of all speeds and feeds are provided. Spindle speed on a large facing head operation can be adjusted without stopping the cut. Use of three Reeves variable speed drives, one motor driven unit directly on the head for the spindle speeds, one Moto-Drive for the spindle feeds and another for all other feeds almost halves the number of gears, shafts and operating levers. All feed and rapid traverse control is directional. All control levers are provided with slotted portions so that it is impossible to engage a hand crank and apply the specific feed or rapid traverse at the same time. The traverse of the head is 72 in., that of the saddle is 60 in., and that of the table 72 in.



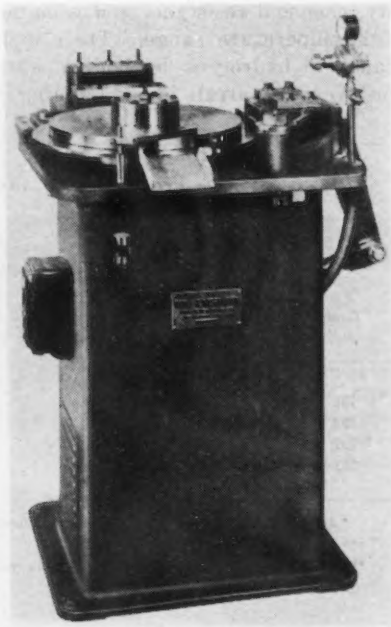


Gear Shaving Machine

A 75,000 lb. Red Ring gear shaving machine is announced by *National Broach & Machine Co.*, 5600 St. Jean Avenue, Detroit, and is said to be the largest of its kind ever built. It has a base of 20 x 20 ft. 11 in. and stands nearly 11 ft. above the floor line. It will shave gears from 24 to 96 in. pitch diameter. It is designed for rotary crossed axes shaving, the cutting tool being free to rotate. The cutter head is equipped with vernier scale and sine bar so that angle settings can be accurately duplicated. By means of a checking head, characteristics of the work gear may be checked while in the machine. Such checking includes the size of the work gear, the amount of shaving stock on it, its linear pitch, wobble, eccentricity and pitch diameter. The headstock is a self-contained unit with its own motor drive. The cutter head and checking head are mounted on a saddle and this saddle assembly is also a self-contained unit with its own motor drive. The slide is reciprocated across the face of the work gear during the cutting cycle, which can be either manually or automatically controlled. Pressure lubrication is used throughout.

Marking Machine

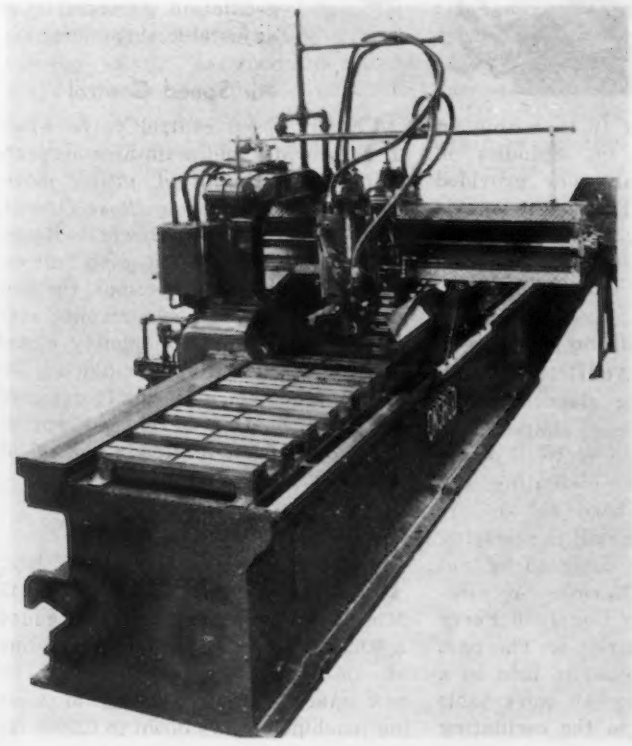
A COMBINATION high speed precision marking and knurling machine has been placed on the market by the *Noble & Westbrook Mfg. Co.*, Westbrook Street, East Hartford,



Conn., which may be used to impress the knurling, customer's name, part number and other identification data into socket wrench parts. The pieces are loaded on a continuously revolving carrier dial and then carried along to the point where they are knurled, marked and unloaded automatically. Although this particular machine is tooled up for socket wrench parts, it can be used in the marking or knurling of other similar parts. The knurling is accomplished with concave knurls under pressure to produce either angular or vertical crossline scores.

Aircraft Milling Machine

A HIGH speed milling machine has been designed by the *Onsrud Machine Works, Inc.*, 3945 Palmer Street, Chicago 47, for milling long, flat, bevel surfaces on aluminum-alloy aircraft wing and fuselage sheet stock. Basically the machine consists of a long bed and T-slot table on which the work is held, while a carriage travels over the bed to move the two vertical cutter heads along the work. The cutter heads may be tilted up to 15 deg. off perpendicular. For a constant or straight line bevel, work is set up on the table so that the bevel milled will be parallel to the length of the bed and the cutter heads are set at the required angle. End mill or fly type cutters are directly driven at 3600 r.p.m. by 15-hp. motors. A bevel up to 110 in. in length may be milled using one cutter motor, and a bevel up to 78 in. long may be milled using two cutter motors. Bed sections may be added for longer work. For a bevel on a taper or crosswise edge, the work is milled by moving the cutter head in a vertical or untilted position across the bridge arm screw. Work is held in a fixture in a tilted plane to the angle of the bevel required. A centrifugal bearing preloader on the motors helps maintain the 0.0001 in. accuracy of the milling operation. A specially designed vacuum chuck is employed to hold work.



Form Miller

TO form mill the radii and angle on the inside of propeller barrels, a special milling machine has been designed by *Sundstrand Machine Tool Co.*, 2555 11th Street, Rockford, Ill. An angular H.S.S. milling cutter with a radius on the bottom is mounted directly to the spindle, which is driven by a 10 hp. motor through V-belts with pick-off gears provided to furnish spindle speed changes in a ratio of 30:1. The workpiece is held in a special fixture mounted on a 22 in. diameter rotary table, which is supported on widely suspended bearings. The automatic cycle provides cross feed to the column, vertical feed to the head or rotary feed to the table, all timed and interlocked with the starting and stopping of the spindle and coolant flow. Similar machines can be provided for profile milling operations. Sundstrand hydraulic feed actuation is provided and the rotary table is driven by a fluid motor.

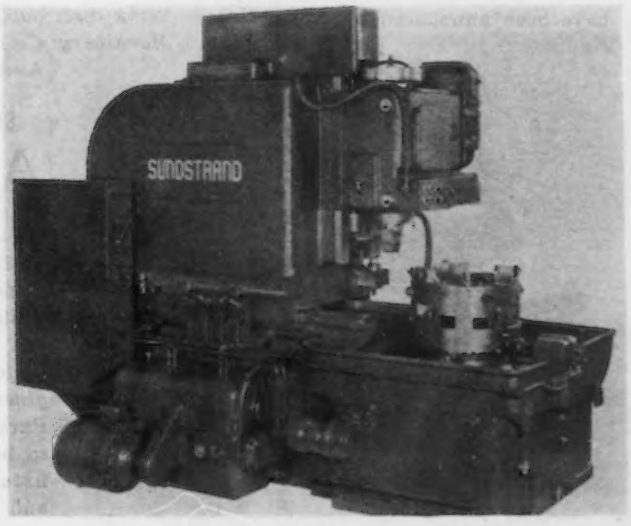
Index Base for Millers

AUTOMATIC index bases have been designed in 8 and 12 in. diameter tables for mounting in horizontal and vertical positions by *Sundstrand Machine Tool Co.*, 2555 11th Street, Rockford, Ill. Mounted in the vertical position, the base can be used

with a tailstock for milling splines, keyways, slots and similar operations. In the horizontal position, it can be used with station type indexing which makes it possible to load one part while another part is being machined. They are manufactured for use on Sundstrand hydraulic Rigidmils and Electromils.

Plain Milling Machine

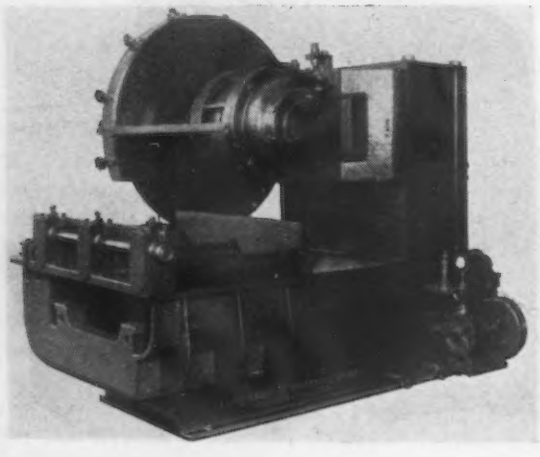
A PLAIN milling machine has been added to the line of surface grinding machines made by *Abrasive Machine Tool Co.*, East Providence, R. I. The B-11 is a man-



ufacturing-type unit with complete electrical control for table and spindle power movements. A built-in backlash eliminator on the table screw is released automatically during fast travel. This permits climb milling in either direction. Other features include automatic reverse, fast table travel of 300 in. per min. and a wide selection of feeds and speeds. Additional sets of dogs and extra table motor controls may be used to widen still further the choice of milling cycles provided.

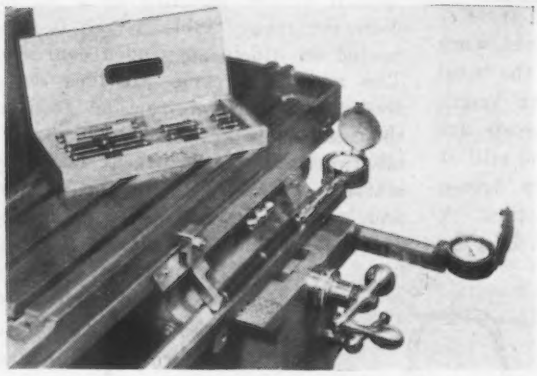
Friction Saws

NINE different models of high speed friction saws in downstroke and horizontal stroke styles have been announced by *Kling Bros. Engineering Works*, 1320 North Kostner Avenue, Chicago 51. The saws are designed for cutting steel rails, structural shapes, tubes, round and square bars and for removing risers from steel castings. The standard friction saws have a horizontal blade stroke which presents the cutting portion of the blade to structural shapes in such a manner that they may be cut square while resting on the work table against the front barrier without clamping. Saw contact is held to a minimum. The saws are equipped with adequate water heads for use in all cases.



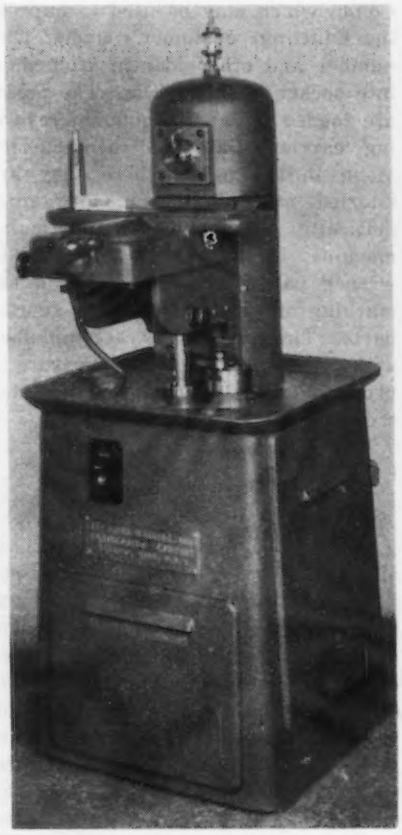
Precision Vertical Miller

FOR doing precision work on Index mills, the *Index Machine & Tool Co.* is prepared to furnish measuring rods, indicators and micrometer heads. With this equipment it will be possible to locate and bore holes in an area 8 x 16 in. within an accuracy of 0.0001 in. Spindles on these hand mills are now provided with power feed. The equipment is being distributed by *Blank & Buxton Machinery Co.*, 3100 East Michigan Avenue, Jackson, Mich.



Slot Milling Machine

A MACHINE for milling slots in pieces of various shapes and sizes with a two-lip end until by oscillating the spindle head in an arc while the mill is revolving has been designed by *Superior Machine & Engineering Co.*, 1930 Ferry Park, Detroit 8. The part to be slotted is held in a fixture on the work table and fed to the oscillating spindle at each end of the stroke. The amount of feed to the table is adjustable and the operation is automatic. The width of slot is determined by the diameter of the cutter and the length of sloth by the chord of the arc of oscillation, governed by an adjustable throw crank.

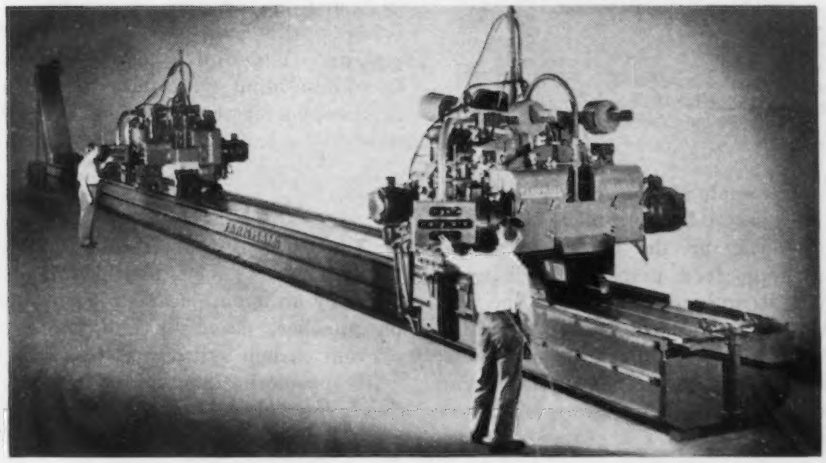


Air Speed Control

AN air speed control valve which provides and maintains accurate split-second timing of piston movements is announced by *Ross Operating Valve Co.*, 6459 Epworth Boulevard, Detroit. Starting with full capacity flow in both directions, the flow in one direction can be controlled over a wide range to a completely closed position through a vernier-like adjustment mechanism. A specially designed stem and floating bevel seat poppet maintain a positive steady control at any selected speed.

Arbor Spacer

FOR close tolerance milling jobs, the *Detroit Stamping Co.*, 345 Midland Avenue, Detroit, has added a 0.0015-in. metal spacer to their line of De-Sta-Co. arbor spacers. The new spacer permits setting of milling machine cutters down to 0.0005 in.



Large Spar Miller

THE *Farnham Mfg. Co.*, Seneca and Elk Streets, Buffalo, announces the delivery of the largest spar miller ever made to a well-known aircraft manufacturer. Overall length is 91 ft. with a table length of 80 ft. Two carriages, having a total of six milling spindles, travel the length of the bed during the milling operation. The two carriages operate independently of each other. They are used simultaneously when milling long spars, performing as many as six operations at a time, or independently on short spars. Horsepower for the spindles ranges in three figures. The machine was designed for Farnham by *Paragon Research, Inc.*

Large Hacksaw Machine

TO meet the need for a saw to cut off or trim large billets, blocks and forgings, *Armstrong Blum Mfg. Co.*, 5700 West Bloomingdale Avenue, Chicago 39, has designed the No. 24 Marvel universal hydraulic roll-stroke hacksaw machine. Nominal capacity is 24 x 24 in. and maximum is 25 x 26 in. The machine weighs 16,000 lb. and covers a floor space of 56 x 122 in. The extreme height is 151 in. It employs low pressure feed and roll-stroke cuting action. All moving and essential machine parts are fully enclosed and protected against abrasive dust and dirt, as well as rough usage incidental to large work. The machine takes a special blade 36 in. long, 4½ in. wide and ⅛ in. thick, with 2½ teeth per in. The blade is of the unbreakable composite type, employing high speed steel teeth and a tough alloy body.

Hand Miller

A NEW development in the form of a lever, rack and pinion transverse feed arrangement for the Nichols milling machine is announced *by the Nichols-Morris Corp.*, 50 Church Street, New York. It can be substituted for the regular transverse feed screw to give to the milling machine table and saddle the same flexibility of movement found in the conventional lathe carriage and cross slide. Work can be chucked lathe-fashion on the spindle with tools mounted on the table or vice versa. This feature of rapid transverse motion, combined with high spindle speeds and carbide tipped tools, makes it possible to use the miller for boring, facing, counterboring, turning, profiling and recessing. Close tolerances can be held on repetitive operations by means of adjustable stops.

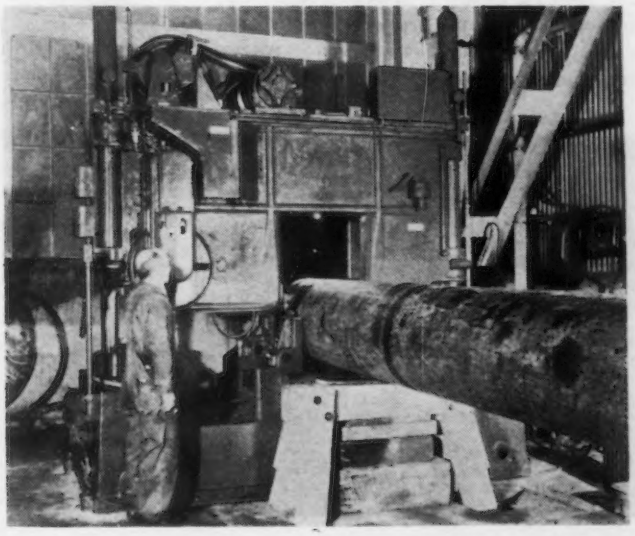
Sleeve Stamp Holder

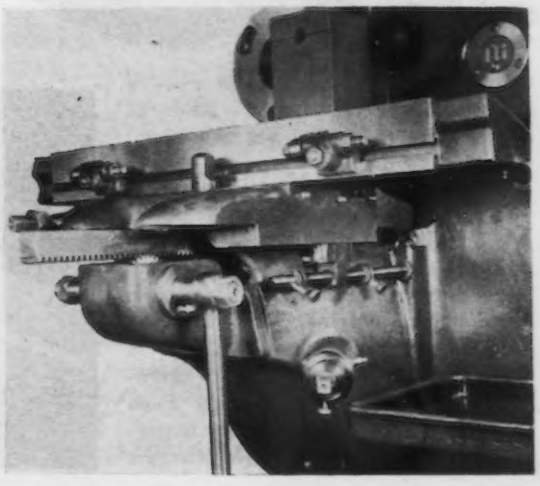
THE M. E. CUNNINGHAM CO., 115 East Carson Street, Pittsburgh, is marketing a safety sleeve holder designed to assure a clear, even impression in marking on small, round, and square pieces, such as gun barrels and small tubes. The top section is knurled for positive grip, and a special pin, easily

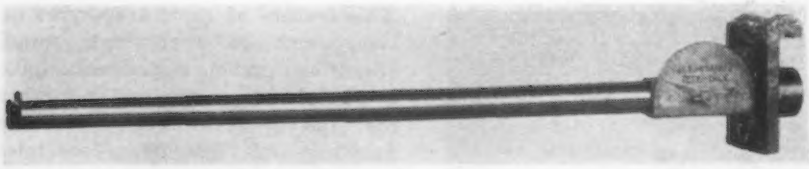
removed for quick change of steel type inserts, holds the holder in place. The device can be made with any size or number of characters.

Deep Hole Indicator

TELL-TALE indicators from 58 to 100 in. long, for holes of 2½ in. diameter or larger have been brought out by *Lehmann Machine Co.*, Chouteau and Grand Boulevard, St. Louis 3. The unit shown is adapted to mount on a hexagon turret face but other mounts can be furnished.



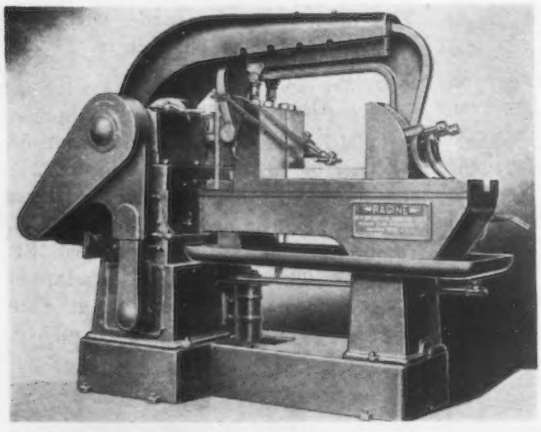




The Tell-Tale is introduced into the hole in the work, the roller on the end contacting the upper wall of the hole. The work is revolved slowly and the runout is indicated in thousandths of an inch on the dial. Two indicators are provided, both adjustably mounted; one may be set for a plus and minus reading, the other for total runout.

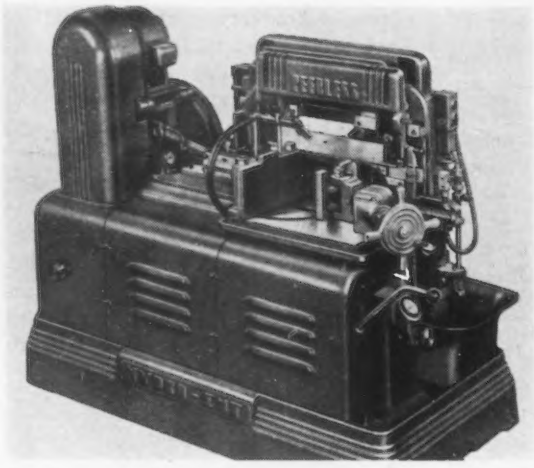
Metal Cutting Machine

THE development of a 20 x 20 in. capacity metal cutting machine has been announced by the *Racine Tool & Machine Co., Racine, Wis.* Designed primarily to provide low cost cutting with a thin cutting tool in large size materials, it is claimed that the machine is particularly adaptable to use on die block steel. The comparatively light-weight blade removes only a small amount of metal in the form of chips. The unit is hydraulically operated. A special dual type feed is used which provides a fast-cutting speed in light materials and yet is arranged for a positive predetermined rate of cutting in die blocks, alloys and tool steel. A three-speed transmission gives cutting speeds of 55, 85 and 115 strokes per min.



Metal Sawing Machine

A NEW hydraulic unit is incorporated in the metal cutting power saws offered by *The Peerless Machine Co.*, Racine, Wis. The hydraulic micro-set length gage is mounted on the conveyor to accurately gage the length of cut. Feed pressure is adjusted by vernier finger-tip screw control. A four-sided saw frame completely surrounds the blade and work. A backing-plate blade support backs up the blades to permit maximum feed pressure with minimum strain on the blade. The saw frame is balanced in its reciprocating travel by dual hydraulic cylinders. The 7 and 11-in. automatic models can be converted for handling a single bar or a nest of bars or tubes.



Blind-spot Rivet Gun

THE riveting machine gun put on the market by *R. Decat*, 78-21 Queens Boulevard, Elmhurst, Long Island, N. Y., is made out of a light weight aluminum casting. Composed principally of a barrel, it contains the rivets in a mandrel with an upset head working as a magazine feed by means of a crank-operated cam. The rivets, threaded on piano wire mandrels, are insterted in the gun as required, it being possible to upset 1200 rivets per hr. The unit weighs only 3¾ lb. These blind rivets may be driven in unsupported sheets and have a positive side expansion of 0.030 in.

Hot Forging Agent

HOT forging processes, particularly in shell production, are aided by an agent swabbed or sprayed on punches, mandrels and rings to prevent carbon build-up and scratches while promoting speed and die life. *E. F. Houghton & Co.*, 303 West Lehigh Avenue, Philadelphia, has developed a series of hot forging agents which are meeting the demands of munitions production schedules. To meet these requirements, the necessary graphite content, high flash point and wetting action are combined in an agent which is said not to build up on the ram or cause scoring.

Seal-less Coolant Pump

A SMALL-SIZED seal-less coolant pump, designed for providing coolant flow to hand mills, surface grinders, internal grinders, drill presses and tapping machines, has been put on the market by *Pioneer Pump & Mfg. Co.*, 19650 John R Street, Detroit. Less than 16 in. high, Model MVBD has three outlets, which permit a choice of piping arrangements—to the right, left or back into coolant sump through intake bracket. It can be mounted on outside of coolant tank or machine pedestal and is said to function efficiently with an extremely low water level.

is it possible to build a rat?

IN the answer to this extraordinary question is a curious story. For two scientists once posed that very question to themselves . . . and the answer was Yes!

They actually built a machine with the power to "learn" by experience and "remember" what it had learned—a mechanism capable of simulating the rudimentary behavior of a rat. Comprised of solenoids, gears and relays, it traveled a grooved track forked by 12 dead-end side-tracks—equivalent to the blind alleys which a living rat encounters. Set to take the dead-end forks, as if by an inner compulsion, this robot rat literally learned by experience to avoid the frustrating blind alleys, in a perfect mechanical analogue to the conditioned reflexes of the brain.*

To build a machine that would reproduce *all* the behavior of a rat "would require a mechanism probably as large as the Capitol at Washington"—*but it could be done!*

For we're at the beginning of an amazing new technological age. Already there are many kinds of thinking machines in our incredibly mechanized world, helping to speed production, cut costs and build better products. And intimately a part of this whole story is the science of machine tool engineering.

Today, Jones & Lamson engineers are working with the leading manufacturers in virtually every industry, helping them to plan production *now* for the machines and the products of tomorrow.

They are at your service, too.

* *In "The Advancing Front of Science" by George W. Gray, a memorable chapter on thinking machines reports this story in full.*

JONES & LAMSON
MACHINE COMPANY
SPRINGFIELD, VERMONT, U. S. A.

Profit-producing Machine Tools

Assembly Line . . . STANLEY H. BRAMS

• Charles E. Sorensen resigns from Ford. His duties will likely be assumed by Ray Rausch, with Harry Bennett still more active in company's administration.

DETROIT—Once again the direction of the destinies of the Ford Motor Co. have undergone a profound change. Last weekend saw confirmed the resignation of Charles E. Sorensen as vice-president and manufacturing head of the company. The effect of the resignation, so far as company operations are concerned, parallels the significance of the death of Edsel Ford last May.

Ill health was the reason attributed to the resignation of Mr. Sorensen, who was by far the best known manufacturing man in the auto industry since William S. Knudsen left General Motors to go into government service. Undoubtedly the physical condition of Mr. Sorensen largely dictated his withdrawal, and it must be recorded that recent events at River Rouge growing out of his illnesses pointed to the likelihood of such an event.

Practically the entire career of Mr. Sorensen has been spent with Ford. He went to work as an apprentice patternmaker in Buffalo, in 1895, and joined Ford in 1904, second year of existence of the then-infant company. He moved up from a foundry post to take a share in administrative operations at Highland Park. His thoughts on mass production by assembly line methods ran parallel to those of Henry Ford. His experiment of testing the idea by towing a chassis on a rope along a hypothetical chain of production stations proved the plan to the satisfaction of Mr. Ford, and won for him the confidence of the company founder. When the plant moved to River Rouge, starting in 1918, Mr. Sorensen rose quickly to the topmost rungs of authority.

In recent years, particularly since the war began, the center of gravity of Ford operations has been shifting from Mr. Sorensen to Harry H. Bennett, one-time personnel head, who is certainly closer today to Henry Ford than anyone else in the company administration. Public recognition of the increasing stature of Mr. Bennett in the Ford scheme of things first came last June, when he was made a director of the company (THE IRON AGE, June 3, 1943, page 70). Subsequently he was designated an assistant on administration to Mr. Sorensen, and at the same time this move was made, R. R. Rausch was designated a manufacturing assistant to Mr. Sorensen. These two moves were generally interpreted as evidences of a movement of administrative responsibility away from Mr. Sorensen.

The poor health of Mr. Sorensen certainly was a major factor in these administrative revisions. The job of building Willow Run and making it function was directly in Mr. Sorensen's hands from the start, and obviously was a terrific job for any one man. He suffered an attack of pneumonia last year and several times was forced to take enforced rests, some of them of months' duration, at his home in Miami Beach where he was staying when word of the resignation finally became public.

AS a result of the inability of Mr. Sorensen to devote constant attention to operational problems, Mr. Bennett quite logically moved closer into the center of the Ford stage, and changes began to ensue in lower tiers of management which naturally reflected the turn of events at the top. Shifts were not uncommon through the latter half of 1943 among executives of a number of departments, manufacturing, and administration alike, and the indications were fairly definite that these changes reflected the desires of Mr. Bennett.

With no public announcement, forthcoming as yet, it was assumed that Mr. Rausch would take over the functions of Mr. Sorensen in major degree. It could be assumed that the operating head of Willow Run, M. L. Bricker, who was also designated a director last June, would likely broaden his operations.

At the same time, general belief existed that Henry Ford would continue to place more reliance on Mr. Bennett as an actual general operating head of the Ford works and its outlying activities as well. In this chain of development must also be considered young Henry Ford II, 26-year-old grandson of the company founder, whose direction toward the higher "front offices" was indicated a few months ago when he was named vice-president in charge of sales and started down a course of grooming in the administrative offices.

ON the score of postwar thinking, Timken-Detroit Axle Co. is attracting attention with a new booklet, "Super Transport on Super Highways," intended to open up horizons of imagination for postwar commercial vehicles. There is less "airbrush engineering" in the designs by Lurelle Guild presented in this book than there is in most such conceptions. Some of the ideas have positive advantages.

There is, for example, the intercity truck with power plant space placed in the center and the front end split vertically into two areas whose top sections slide into the roof, and whose lower sections drop down to form a step. The right half can thereby be used for loading in addition to conventional facilities in the rear.

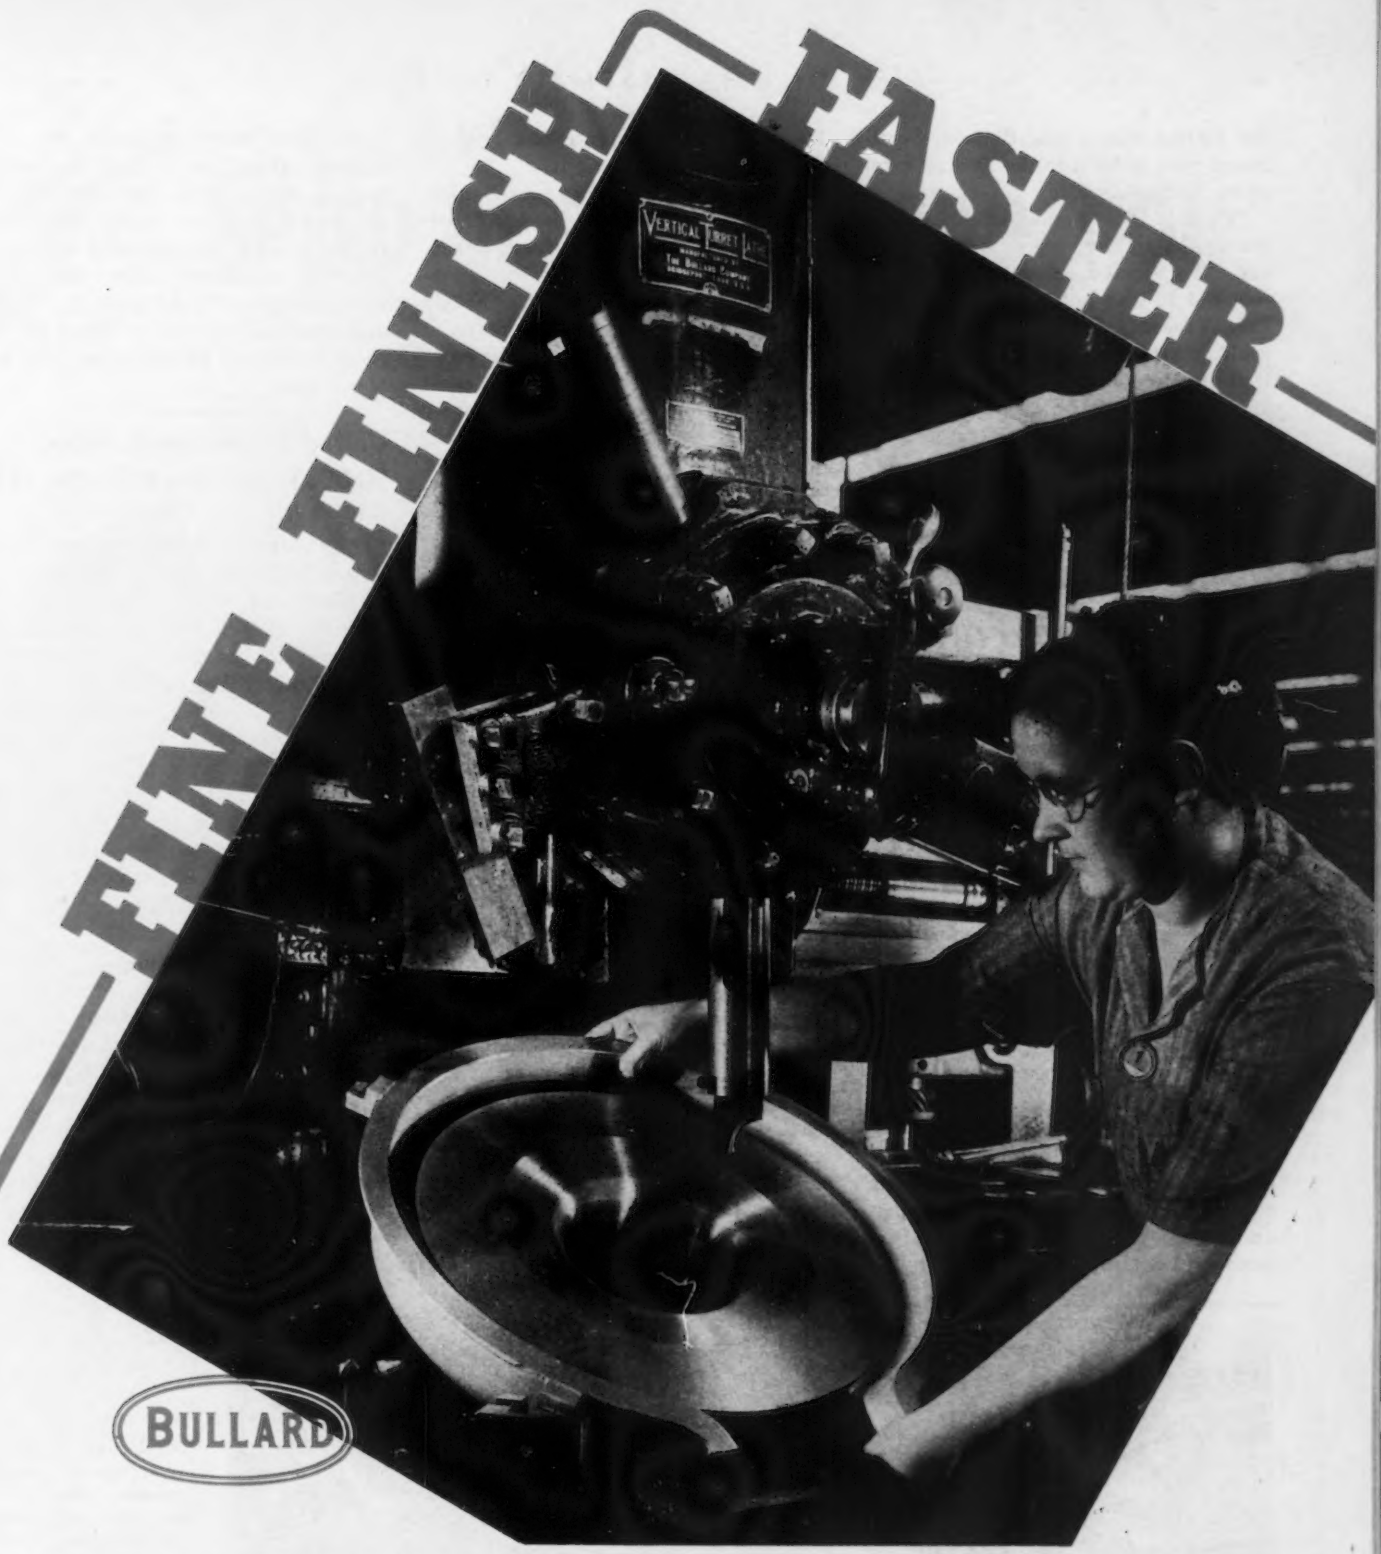
One of the most revolutionary ideas is that for a highly specialized dump truck with cab mounted on the side. The objective is visibility in either direction, utilizing a steering-driving axle at each end which permits driving in either direction and load dumping fore or aft. Presentation of this idea is used by Timken to emphasize the Army finding that specialized vehicles work faster, better, and at lower cost.

Supplemental material in the booklet reveals that Timken now has four plants: The headquarters at Detroit and subsidiary operations at Melvindale, Mich.; Oshkosh, Wis., and Waukegan, Ill. The Melvindale plant, newest of the Timken-Detroit units, is now in process of completion.

A BOUQUET was laid at the door of Packard Motor Co. by Hubert Scott-Paine, the English boat builder, in a recent speech before the Detroit section of the Society of Automotive Engineers.

Discussing the developments leading up to the torpedo boat fleets of

FINE FINISH FASTER



Do the products you make have to be held to fine limits? The rigid vertical design of the Bullard Vertical Turret Lathe is assuring fine limits in scores of vital industries. Are you striving to exceed quotas already high, with a dwindling supply of skilled labor? The V.T.L. saves time by cutting with two heads at once . . . saves time between cuts. Today, as America's production rises to incredible heights, the Vertical Turret Lathes play their part in bringing this war to the "finish" we all desire. Tomorrow, these same advantages will weigh heavily in their owners' favor in the battles of peace-time competition.

BULLARD VERTICAL TURRET LATHES

THE BULLARD COMPANY

BRIDGEPORT 2, CONNECTICUT

the United States and Britain, Scott-Paine paid tribute to the Detroit company in these words:

"I would like to stand off for a minute and say a few words about Packard. We started off with a 1300-hp. job, but it was not what we wanted. Col. Vincent, his engineers, and I really started work somewhere around October-December of 1939. In April of 1940, the engine was finished and did its first hundred hours' testing without any trouble.

"We have been building aero engines since 1909 anyway. That is the most rapid construction I know of. There is no other place but Detroit, of course, that could do it.

"We never had any mechanical trouble at all—it has been a first-class job. It has grown from 80 engines in the original order into thousands, and it is running pretty nearly every PT, MTB and rescue vessel. I cannot help feeling that it will come through this war as one of the most outstanding engines. I do sincerely hope that the Packard and the men connected with it get some kind of recognition, because if they had not done this there would be no engine to run these boats."

Liberty Ship Failures Debated at Senate Committee Hearing in New York

• • • **After hearing** a witness estimate that about 60 of the nation's fleet of almost 2000 Liberty ships developed major structural failures after they were put in war service, Senator Mon C. Wallgren, Democrat of Washington, advocated on March 2 immediate abandonment of a program to convert some of these vessels into hospital and troop ships. He added that the entire Liberty ship construction program should be given up in favor of construction of speedier vessels.

Senator Wallgren expressed his opinion at the ending of a public hearing by the Truman investigating committee, of which he is a member, on causes of structural faults that have caused some Liberty ships to break up and sink. The hearing was held in the United States Courthouse on Foley Square in New York.

J. Lyell Wilson, assistant chief surveyor of the American Bureau of Shipping, minimized the importance of the amount of fractures developed. A thousandfold of trouble was expected in such quantity production by companies using many inexperienced men, he added. He said some of the fracture trouble already had been overcome; that only 3 per cent of the Libertys built had developed serious cracks or fractures, and that this figure had dropped to 2 per cent last Summer. After repairs ships that developed cracks were better than new because the stresses had been relieved, he added.

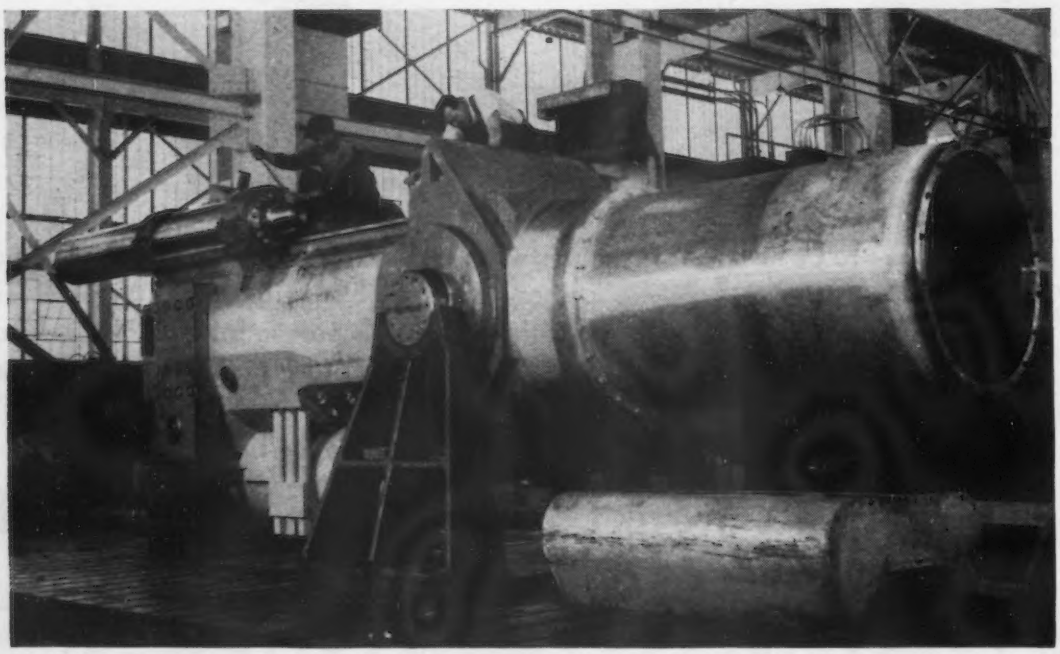
The testimony brought out that Liberty ships in ballast, or partly loaded, operating in cold water routes developed fractures sooner than fully loaded vessels. The majority of cracks reported occurred when the ships were returning to this country "light" and ran into storms. Most of the cracks occurred in the vicinity of the No. 3 hold.

United States Sends Allies 28,000 Planes Since March, 1941

Washington

• • • **Almost 28,000** airplanes have been sent by the United States to the air forces of allied nations, together with $1,600,000,000 worth of aircraft engines and parts since Lend-Lease started, according to Leo T. Crowley, Foreign Economic Administrator. Since March, 1941, 150,000 aircraft have been produced in this country, of which 122,000 were retained for American use. Of the 22,000 shipped abroad, 21,000 were sent under Lend-Lease provisions and the other 7000 were paid for in cash, principally by the British.

A total of 7800 planes went to Russia, 4000 to Allied forces in the Pacific and Far East, and more than 16,000 to all other combat and training areas abroad. About 75 per cent of the planes have been combat types and the balance trainer and transport planes. There have been 9800 four-engine, two-engine, and single engine bombers and 10,700 single and two-engine fighter craft shipped abroad.



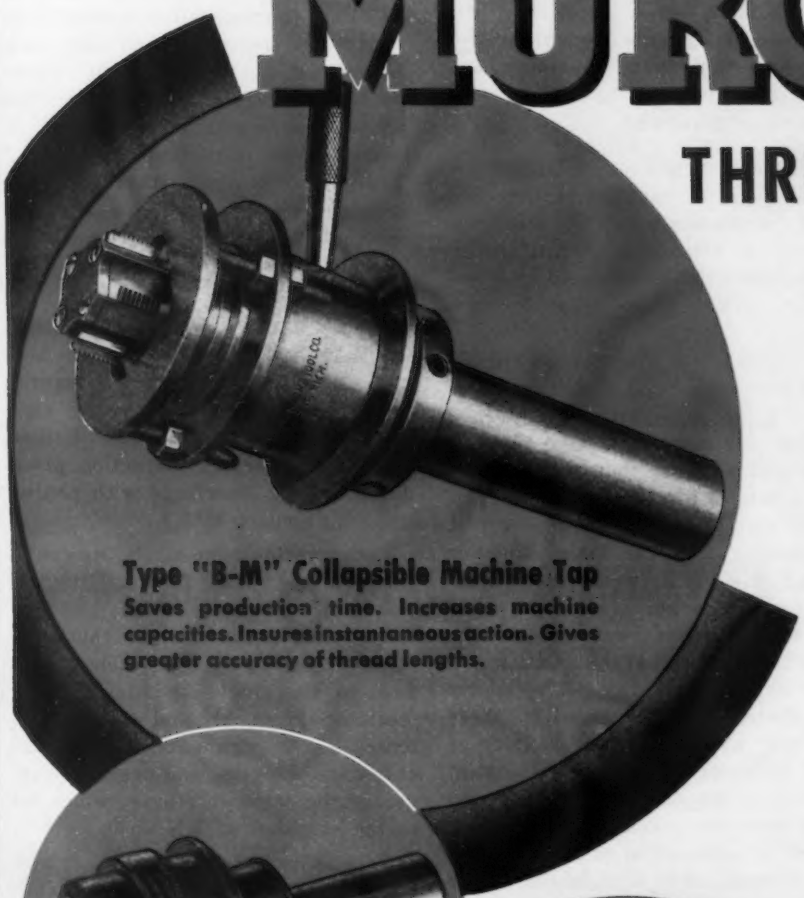
NAVY GUN MOUNT — *Resembling a giant cannon, this 25-ton mass of precision-finished steel is the stationary housing for the recoil mechanism of a 16-in. Navy gun. Nearly ready for sea duty on one of Uncle Sam's battleships, the housing gets a final check at the Naval Ordnance Plant operated by the Westinghouse Electric & Mfg. Co., at Louisville, Ky.*

You Can SPEED UP YOUR PRODUCTION

on Threaded Parts for Tanks, Guns, Bombs, Shells—with

MURCHEY

THREADING TOOLS



Type "B-M" Collapsible Machine Tap
Saves production time. Increases machine capacities. Insures instantaneous action. Gives greater accuracy of thread lengths.

Type "C-O" (rotating) Self Opening Die Head
A companion to Type "G" for use on machines where the die head revolves. Takes the same chasers as well as many parts of Type "G".

4 Weeks Delivery

Murchey gives you the better, faster and more accurate threading you need to speed up your production on threaded parts. And Murchey quick delivery enables you to start your increased production schedules much sooner. Hurry and get full information on Type "B-M" Collapsible Machine Tap and Type "G" and Type "C-O" Self Opening Die Heads.

Catalogues on request—write today. Also get information on Murchey Thread Milling Machines, Shell Tapping Machines, and Roller Pipe Cutting-off Machines.

MURCHEY MACHINE & TOOL CO.
DEPT. 1 • DETROIT 26, MICHIGAN

Type "G"
(non-rotating) Self Opening Die Head
Designed and engineered for use on any machines where die heads do not rotate. Made in sizes from 7/16" up to and including 6".

We still have opportunities for exclusive distributor representation in—St. Louis, Memphis, the entire states of Washington and Oregon; Northern California, the entire states of Idaho, Montana, Nevada, Utah, Wyoming, Colorado, New Mexico, North Dakota and Nebraska. Write for information.

Washington . . . L. W. MOFFETT

• Annual Truman report gives public facts and figures . . . May result in WPB order of limited production of civilian goods . . . Advises relaxed controls on smaller steel companies with idle capacity . . . Urges gradual peacetime changeover from NE steels.

WASHINGTON — As swivel-hipped as a great broken field runner, the latest annual Truman Committee report skirts most of the artificial censorship set up by the Executive Branch of the government to keep facts from the public for political reasons.

The result is a straightforward reporting job on war production and demobilization which favors few sacred cows. The committee and its staff deserve congratulations.

The report crashes through the War Department's objections to resuming civilian production and through making public the facts on cancellations, cutbacks, manpower, materials and plant capacity which will result in forcing the War Department to change its attitude, it is predicted.

Hence, with the Truman report as a springboard, it can be expected that WPB will soon order limited production of civilian goods to utilize surplus materials in areas where manpower demands are slack enough to permit the resumption without interfering with war production.

The conclusion of the Baruch report that competitive position of companies returning to peace production should be maintained so far as possible in plans by the government is met head on with the sound logic that such selection and control is not only impractical, but un-American.

Consequently, it is assumed that no more than 20 major industries will be placed on a quota basis in their readjustment to civilian needs. Heading the list are household electrical goods and automobiles where manufacture is relatively complicated and components and materials will have to be rationed among the various competing companies.

Other subjects the report covers are: Surplus plants and commodities, renegotiation, steel, aluminum, copper, lead, zinc, lumber, mica, aircraft, transportation, farm machinery, tank lighters, and Army and Navy hotel acquisition programs.

IN steel, whenever a substantial drop in operations comes, the report recommends that the strict war controls be relaxed to permit smaller companies with idle capacity to seek "some civilian non-essential business."

In answering the objections of those who would not permit the steel industry to move into civilian production, the committee says that the burden of showing that such permission would injure the war program should rest upon those who assert it.

Asserting that the main objection is that small mills would draw manpower from larger ones who would still be producing war orders, the committee says that this argument is of doubtful validity. The report says that the labor utilized by these mills will not move to the vicinity of other mills engaged in more essential work if it has not already done so in the past two years.

Steel in substantial quantities could be produced today and is not being produced because the finishing facilities available could not make products needed for essential programs. Some of these facilities, however, could make a limited quantity of products suitable for civilian uses, the report states.

THE committee said:

"Pig iron also can be produced in excess of present requirements. This product should be produced and should be made available to small foundries that are located in non-critical manpower areas. Such foundries could produce a large variety of civilian goods without any impairment to war industry. Such small beginnings at this time will serve to take up the slack of employment in many areas and at the same time to produce useful articles."

Hailing the cooperation of the steel industry, and praising it for its 1943 output of 88,838,043 tons, the committee declared that much credit for this achievement should go to the Steel Division, "for a fine job of administration."

CALLING attention to the plate inspection problem at the Irvin Works of Carnegie-Illinois Steel Corp., which the committee had previously condemned as "fake," the report pointed out that the company "had placed exceptionally able men in charge of its inspection department." The committee noted that inspection procedures have been "completely revamped," and that the company is "now producing good steel."

The report commends that WPB has also assured the committee that the steel industry as a whole has been and is now shipping plates in quantity and of a quality to meet the rigid requirements of the services. Utilization of satisfactory inspection procedures has not interfered with production, the report said.

Conservation-minded, the committee plugged the peace-time melting of National Emergency steels, and contended that despite the fact that these steels "cost more" any wholesale return to the single and double alloy steels would quickly and substantially increase the drain on nickel and chromium supplies and create a danger of the same shortages, which led to the adoption of NE steels.

Despite its setbacks, the report says that the expansion program in steel has been entirely successful. "No vital war program has failed, or has been retarded very seriously for lack of steel," and all essential requirements were met in 1943.

OF course, it could be said that the committee has been rather slow in reaching the conclusion that steel output is adequate. In its report of one year ago, the committee still insisted that there had been a steel shortage. The net increase in steel production in the two-year period has only amounted to a few million tons. Production in 1941 was about 83,000,000 tons and in 1942 was 86,000,000 tons. The effect of the expansion program has only made itself felt in the latter months of 1943.

CINCINNATI

Grinding hollow piston rods for hydraulic machines, on a CINCINNATI No. 2 Centerless Grinder equipped with a Type C Long Bar Fixture.

Do You Know the LONG BAR GRINDING POSSIBILITIES of the Centerless

Round tubes, rods and bars of all types of metal are ground quickly, accurately and continuously on the CINCINNATI Centerless Grinder by using Cincinnati engineered Long Bar Fixtures. ¶ For the No. 2 machine, these fixtures are available in three standard sizes. Type A is for bars ranging in diameter from 1/8" to 1 1/4" and lengths up to 2 1/2 feet. Type B for bars 1/8" to 1 1/4" in diameter and lengths up to 8 feet. Type C for bars 1/2" to 2" in diameter and lengths up to 18 feet. For the No. 3 machine, an additional size is available . . . type D for bars 1" to 4" in diameter, and lengths up to 18 feet; and 1/8" to 1" in diameter in lengths up to 8 feet. Then there is the non-metallic bar grinding fixture, for fibre and molded plastic tubes and rods, ranging in diameter from 1/8" to 3" and lengths up to 5 feet. ¶ The engineers here at Grinding Headquarters will be glad to discuss your long bar grinding requirements with you. Catalog G-456-1 gives specifications and full details on CINCINNATI No. 2 Centerless.

● Front view of the CINCINNATI No. 2 Centerless Grinding Machine. Write for catalog G-456-1 which gives complete information on all features.

CENTERLESS LAPPING MACHINES

would be complete without mentioning sponge iron, it is again appraised by the Truman Committee.

Says the report: "However, as insurance for the future, the Bureau of Mines should continue its experiments with sponge iron and other forms of melting stock which can be used in place of scrap. Only one commercial scale plant of this type *(Editor's Note:* Republic Steel at Warren, Ohio) was authorized. It took almost twice as long to erect as had been expected and is almost twice as costly. Nevertheless, it may prove to be successful. But the committee is of the opinion . . . that several other proposed projects utilizing different methods should have been more carefully considered. Had the need for melting stock become acute it would not be satisfied today. By experimenting with several processes the Steel Division might by now have proven at least one."

Dodge Heads Price Adjustment Board

• • • **The War Department** announced Feb. 28 that Joseph M. Dodge, chairman of the War Department Price Adjustment Board, has been named to head the new War Contracts Price Adjustment Board provided for in the Revenue Act of 1943. Function of this board is to fix policies and procedures for contract renegotiation.

Members of the board serving with Dodge are Laird Bell, chairman of the Navy Price Adjustment Board, vice chairman; Commander Arthur G. Rydstrom, Maritime Commission Price Adjustment Board, who is also representing the War Shipping Administration Price Adjustment Board; Capt. Harry C. Maull, Jr., chairman of the Treasury Department Price Adjustment Board; Charles T. Fisher, Jr., chairman of the RFC Price Adjustment Board, and Carman G. Blough, WPB. W. James MacIntosh has been appointed general counsel to the War Contracts Board.

The authority of the board applies to renegotiation for war contractors' fiscal years ended after June 30, 1943, while authority of the Joint Price Adjustment Board — established last October by voluntary action of the various individual departmental boards —applies to war contractors' fiscal years ended before July 1, 1943.

THE BULL OF THE WOODS — BY J. R. WILLIAMS

Portable Tool Orders Fall Slightly

Washington

• • • **The WPB Tools** Division recently indicated that portable electric and pneumatic tools unfilled order backlogs, which increased quite sharply during the early months of 1943, have been slightly but consistently decreased to a level of about $43,000,000. Shipments are high, but slightly under the 1943 peak months.

Such tools include all portable metal working tools powered by compressed air or by a self-contained electric motor which in the course of normal use are lifted, held, and operated by not more than two persons. The data included in the tables are based on returns made by about 65 companies which account for about 95 per cent of all production.

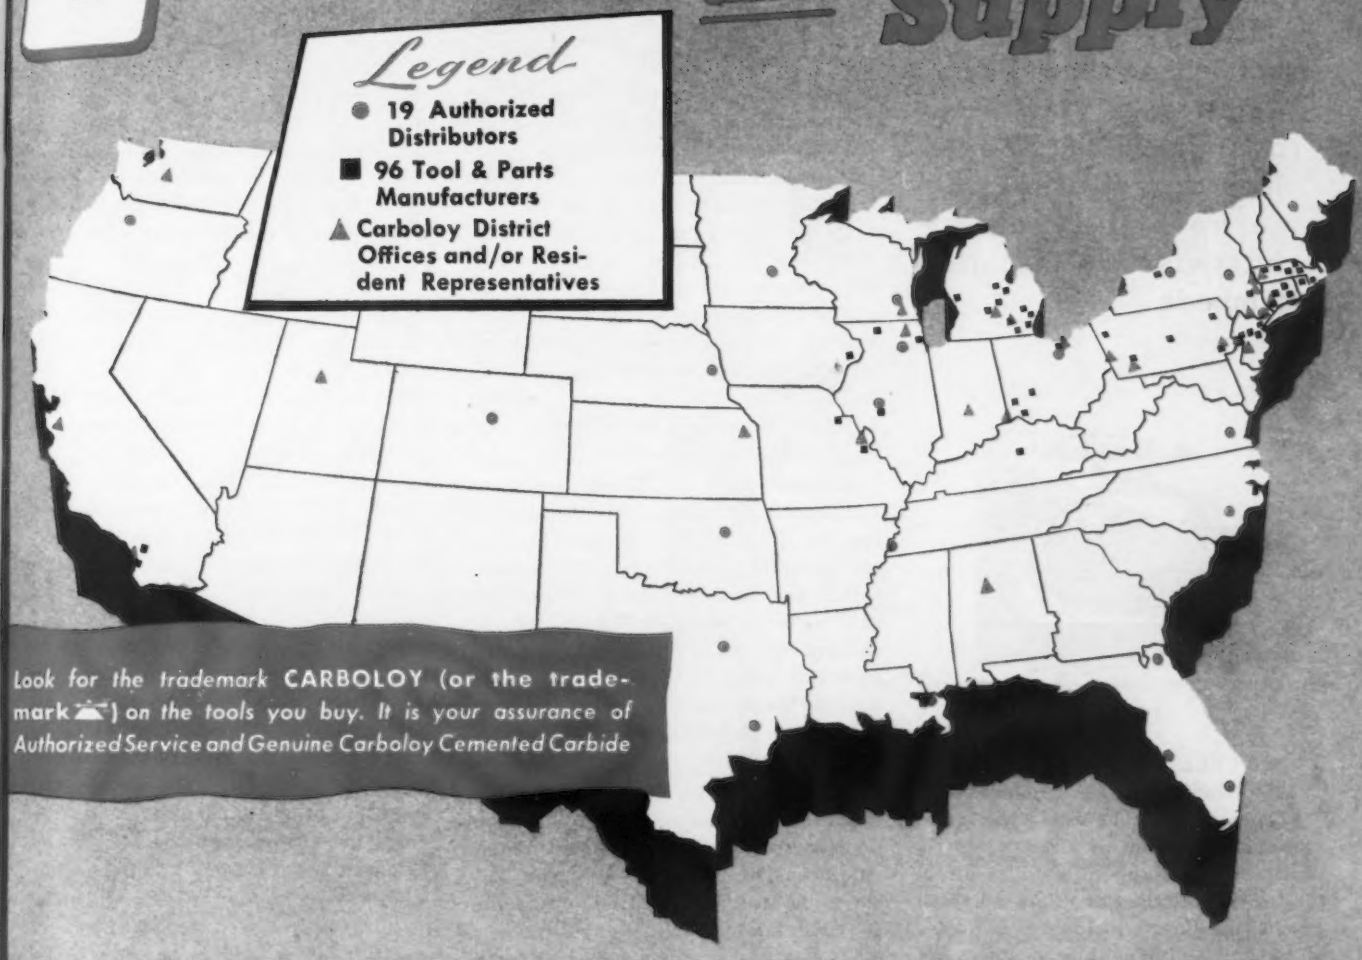
Coast to Coast Service and Supply



Look for the trademark **CARBOLOY** *(or the trademark* ▲C*) on the tools you buy. It is your assurance of Authorized Service and Genuine Carboloy Cemented Carbide*

CEMENTED CARBIDES manufactured by Carboloy Company are available to you under this nationwide 3-way plan of distribution that provides maximum service and availability throughout the entire range of carbide use:—

1. *Through Distributors:* Authorized distributors in important metal-working areas carry stocks of Standard Carboloy Cemented Carbide Tools, Blanks, Dressers and Masonry Drills and offer complete technical service through factory-trained representatives.

2. *Through Tool Manufacturers:* Leading tool and parts manufacturers are authorized to supply their products, covering practically all types of special —often patented—tools, cutters and gages, as well as many miscellaneous parts—equipped with Carboloy Cemented Carbides.

3. *Direct Carboloy Service:* Direct service by Carboloy Company is provided by a large staff of experienced sales and service engineers operating throughout the country.

Put this comprehensive system of service and supply to work for your plant. Specify "Carboloy" for your cemented carbide requirements.

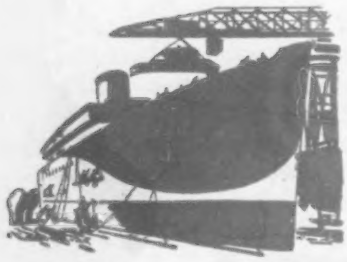
WEST COAST . . . OSGOOD MURDOCK

• Manpower really is short in the volatile Pacific Northwest . . . New wage rates for 6000 Boeing office and engineering workers may cause coastwise white collar stampede.



SEATTLE — When Kenneth B. Colman, Seattle industrialist and ex-president of the local vigorous Chamber of Commerce, recently accepted appointment as director for difficult Region 13 of the War Production Board, including the states of Oregon and Washington with part of northern Idaho and western Montana and most of Alaska, he took on a man-sized task that makes up in complexity what it lacks in statistics and that is geographical and psychological, rather than ponderous and numerical. He must guide the solution of a problem in civilian logistics involving communications and priority urgencies, manpower and industrial relations that is probably more delicate and far-flung and less understood than any in the nation.

Mr. Colman's predecessor, George K. Comstock, also a Seattle business man and a fellow ex-president of the same Chamber of Commerce who had served for a year. Before that time, Oregon. and Washington had been included in Region 10 with headquarters at San Francisco, but pressure for autonomy and freedom from the "yoke of subservience" to California became great enough in the fall of '42 to obtain authorization for the separate WPB region. The War Labor Board has also established a separate Pacific Northwest region, although OPA and •WMC continue to recognize the entire Pacific Coast as the single economic and commercial region which it is, rather than yielding to political, provincial, and home industry rivalries that divide it.

In his furthering of Pacific Northwest war production, regional director Colman is confronted with an actual shortage of some 45,000 good he-men to man nationally essential logging and lumber activities, fishing, shipbuilding and repair, essential agriculture, Boeing aircraft and miscellaneous manufacturing.

Selective Service officials announce that quotas for the state of Washington for the next four months call for the induction of 18,000 men, necessitating the call of 25,000. There are said to be between 30,000 and 40,000 fathers of service age in "not too essential jobs" and the pressure is now on them either to accept military service or directly essential production employment.

Meanwhile the Bremerton Navy Yard is still in need of 6000 workers, largely for repair and maintenance. An intensive campaign over the last three months has secured only 2000 of 8000 needed workers. Moreover, many now manning the yard are farm hands who will be leaving for their equally essential field jobs as Spring comes. Railroads in the Pacific Northwest desperately need some 3000 workers to maintain schedules and handle augmented traffic expected. Major shipyard schedules are being stepped up, as are Boeing's.

VOLATILE, unpredictable strikes are not uncommon in this lusty, uninhibited, still pioneer region. One day last week, for instance, some 600 workers at the Tacoma coppersmelter took a "work holiday" for a strike vote, because nine plant employees were said to be entitled to dust differential pay and there was some question by the management whether these particular men came under this classification which WLB's non-ferrous metal commission has set up. The vote was 518 for a strike to 122 for continued negotiations. Next day everyone went back to work to await the strike.

When the management of a Lake Washington shipyard was unwilling to restore one transferred employee to his former job, a wild-cat walk-out of some 175 machinists slowed up ship construction. The union business agent stated that "we didn't order these men off the job but we won't order them back to work until the matter is settled."

TO 6000 Boeing general office and engineering workers, the regional War Labor Board has granted pay raises supposed to bring office help up to parity with production laborers. The plan adopted is based on the evaluation plan that recently went through for factory workers and sets up 14 different labor brackets. Employees are assigned to each grade on a point basis that takes into consideration the type of work each does, responsibility, and other considerations. The lowest grade for office help has a rate range from 66 to 72c. an hour and the highest from $1.77 to $1.94. Unlike the factory plan which has a flat rate for each group, the new office plan has a range of nearly $15 in each group. The plan will be retroactive to Sept. 1, 1943, and should go into effect within the next three weeks. The plan is subject to approval by the National WLB since there were two dissenting votes by labor members of the regional board.

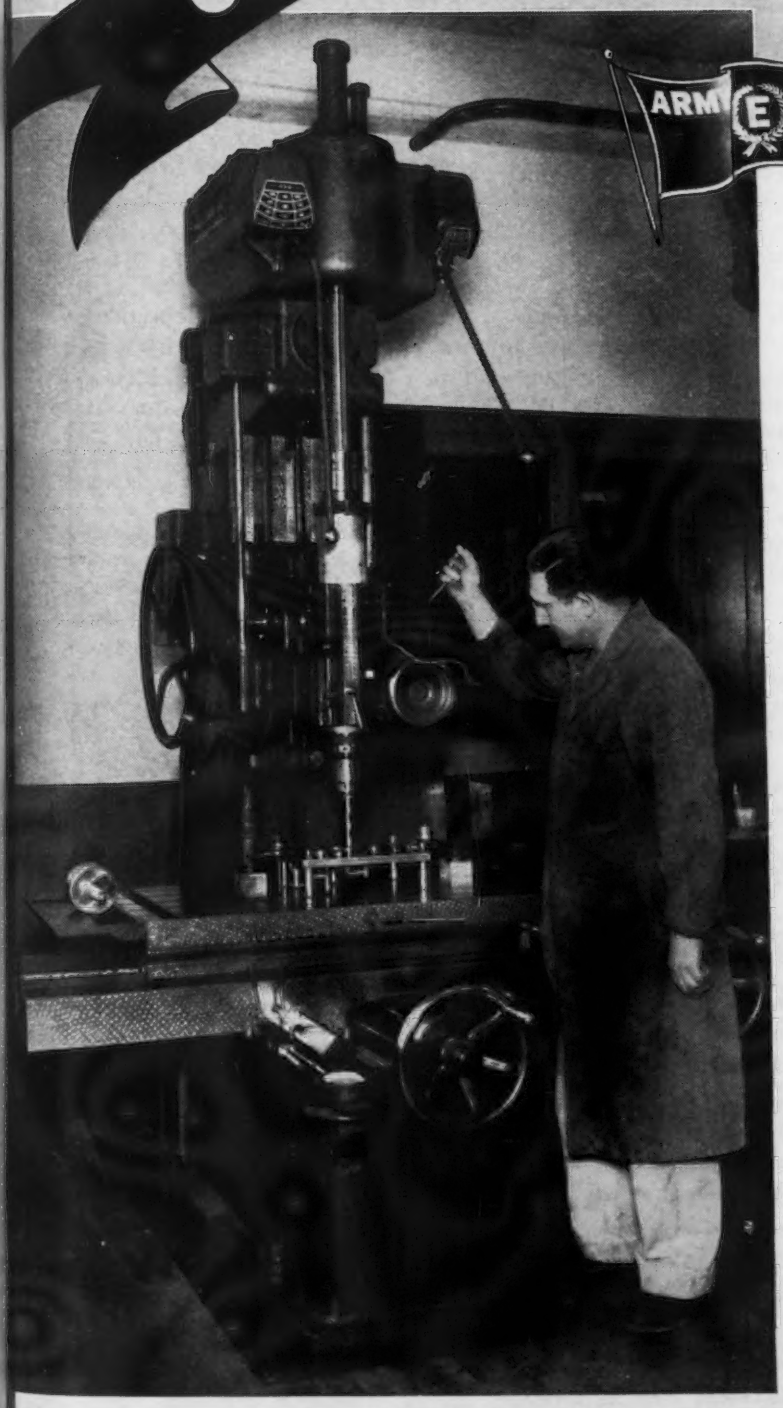
Adoption of this classification and adjustment for office workers on so large a scale is bound to affect similar workers in other plants and industries, particularly shipbuilding and those supplying aircraft. Moreover the eager and well organized aircraft workers in southern California in four or five times Boeing's volume may be expected to press more vigorously their already clamorous appeals for higher pay, better working conditions, more transportation and housing and new contracts.

WHILE Boeing and Bremerton, Kaiser and Sea-Tac vie for their thousands, other comparatively small but crucially important mills, foundries, and fabricators are hard pressed to maintain their hundreds. Although Northwest Steel Rolling Mills, Inc., needs only 50 more workers added to its present payroll of 250, the lack of these workers has closed down the second electric furnace and has cut down the reserve

FOSDICK

FOR TOOL ROOM ACCURACY ON ALL DRILLING OPERATIONS

JIG BORER



● Here is a typical tool room job being done on a FOSDICK JIG BORER. The piece is a cast iron drill fixture base to be used for locating holes in a motorcycle cam case cover.

Accuracy that will permit interchange of these cam case covers is essential. That's why the locating holes are being drilled and finish bored to size on this Fosdick Jig Borer. The hole size is 1.250 inch and tolerances are plus or minus .0005 inch.

The Fosdick Jig Borer is also rigid enough to do light milling operations. On jobs where several operations are to be performed such as milling—drilling—reaming—and tapping—they can all be completed on a Fosdick Jig Borer at one setting. This not only saves valuable time but fixture and tool costs.

Thus versatility—accuracy—and ease of operation makes the Fosdick Jig Borer an ideal machine for a wide variety of close tolerance work both in small lots and in large quantities.

The Fosdick Jig Borer Bulletin J.B.I. gives complete details. Write for one.

FOSDICK MACHINE TOOL COMPANY
CINCINNATI · · · OHI

supply of ingots so that sometimes the rolls have been forced to stop entirely.

LOS ANGELES—Termination of Army training plane contracts with Consolidated-Vultee has been announced, affecting plants at Nashville, Tenn., as well as at Downey (Vultee Field). This reduction in the total number of basic trainers scheduled will cause only a gradual tapering off of production. At the same time there will be an expansion in combat class projects. Both personnel and facilities at Vultee Field are being switched over to work on components for combat types of aircraft.

That transport planes are even more crucially needed than bombers is evidenced by a plea directly from General Arnold, chief of the Army Air Forces to Douglas employees at Long Beach and Oklahoma City, urging on an emergency basis an increase of at least 400 extra C-47 "Sky Train" transports. One of the company's plants just turned out its 3000th transport. Some 10,000 employees working directly or indirectly on this one model are following president Donald W. Douglas' personal leadership in an earnest attempt to exceed this previous schedule. Priorities and preference ratings for the C-47 now exceed all other production models even including bombers, also built at the same plant.

Surplus steel and aluminum inventories are coming into the open for official recording faster than they move. A rough check shows 25,000 tons on hand in southern California owned by contractors and 15,000 tons additional controlled by the Air Corps, of which some is government owned. Since the first of the year some 5000 tons of iron and steel surplus have been sold.

OVER 100,000 tons of contaminated, low grade, orphan scrap may be converted into ship ballast within the next nine months on the West Coast if present pretty tangible plans and prospects mature. In normal times pig iron was frequently used. More recently concrete fortified by heavier ore has been substituted. Surplus turnings and borings have also been bricketted and remelted in cupolas on a small scale. Each Navy Yard has maintained 1000 tons of metal ballast as a pool.

Now comes a demand for over 100,000 tons for new merchant ships to be converted for military purposes within the next nine months. Deliveries would be at Portland, San Francisco and Los Angeles, from 15,000 to 20,000 tons a month. Metal is to be in blocks 4 x 4 x 24 in. It is presently proposed to divert for this purpose all galvanized and contaminated scrap, all tin cans, No. 3 bundles, turnings, borings, and miscellaneous low grade scrap, now dormant or selling below ceiling. What cannot be handled in cupolas may be put through open hearths, rolled, and sheared into bars which are found most practical in that they fit between the ribs of a ship, form a level floor and can be placed with a maximum weight at the lowest point to be ideal for navigating and utilization. A pool is being formed to supply this big prospective market, combining Naval and Maritime requirements.

Steel Casting Inspection Ceiling Prices Established

Washington

• • • **Ceiling prices for** radiographic and magnaflux examination of steel castings were announced by OPA. The extra charges that may be applied for these types of inspections are roughly the same as those currently being charged in industry practice.

For producing castings subject to inspection, regardless of whether the producer performs the inspection or not, he may add to his maximum base prices the following:

1—For radiographic inspection—12.5 to 30 per cent of the base price according to examination specifications.

2—For magnaflux inspection—15 to 30 per cent of the base price according to amperage required.

Where castings are subject to rejection on the basis of both radiographic and magnaflux inspection, however, only the radiographic or the magnaflux extra may be charged, whichever is higher. The production cost extra is added because of the additional expense involved in producing castings subject to these types of examinations.

If the producer of the casting performs the inspection himself, in addition to the foregoing production cost extras he may add:

1—For radiographic inspection—$17 per hr. with a 200,000 to 300,000 volt capacity machine; $21 per hr. with a 300,000 to 500,000 volt capacity machine; $25 per hr. with a 1,000,000 and over volt capacity machine.

2—For radium inspection—$5 per hr. for capacity of 10 to 500 milligrams.

Where the producer lets out inspection to an independent laboratory, he may add to his maximum base price the actual inspection cost to him plus 10 per cent. Where the producer performs the inspection himself, the cost extra needs in no case be less than $10 for a single order.

OPA also announced that steel casting producers who perform special services not specifically provided with ceiling prices, such as galvanizing may submit proposed prices for such services for approval.

He's straining every nerve to give you SHEET STEEL SERVICE

THE ARMCO DISTRIBUTOR is in the same predicament as others or us. He has just so much sheet steel (his quota limitation); he's up against the same manpower shortage that no doubt plagues you; and he can't provide ARMCO *sheets plus service* with that pre-war speed you liked.

But don't hesitate to call the Armco Distributor, because he'll make every effort to handle your order or give you helpful suggestions.

A STRONGER POST-WAR SERVICE

While "the going is tough" now, the Armco Distributor is planning better things for you. After the war he not only will offer you the most complete line of special-purpose and commodity sheets, but a broader, swifter and closer service.

SHEETS FOR EVERY PURPOSE

Here are some of the possibilities in sheet metals: Galvanized ARMCO Ingot Iron; galvanized PAINTGRIP; ZINCGRIP; ZINCGRIP-PAINTGRIP; Stainless Steels; Aluminized Sheets; Enameling Sheets; copper-bearing and regular steel sheets.

So whether it's now or after the war, remember that the Armco Distributor wants to serve you to the limit of his ability. Every day brings him nearer the time when he can give you the ALL that he wants to give you—in special steels, application service, deliveries, or all three. The American Rolling Mill Company, 1011 Curtis Street, Middletown, Ohio.

SPECIAL PURPOSE ARMCO SHEET METALS

ARMCO *DISTRIBUTOR SERVICE*

PERSONALS

• **Ralph O. Smith** has been appointed general sales manager of the Vulcan Iron Works, Wilkes-Barre, Pa. Mr. Smith has been with the company since 1918.

• **Joseph F. O'Brien** has been made an assistant to the president of Vulcan Iron Works. Mr. O'Brien, who started as an apprentice in the Vulcan shops more than 30 years ago, will have charge of all matters relating to operation and production.

• **Jack J. Chernyk,** on leave from the United States Army, now is managing the Chicago Alloy Products Co., Chicago, succeeding **Ben Chernyk,** founder and president, who died Feb. 15.

• **Donald Rae,** chief mechanical engineer, Package Machinery Co., Springfield, has been made assistant superintendent.

• **N. M. Barnett** has been made manager of the Chicago branch office of the Bailey Meter Co., Cleveland. He succeeds **M. Greenberg.**

• **W. H. Feldmann,** vice-president and general manager since 1940, has been elected president and general manager of Electric Machinery Mfg. Co., Minneapolis. He has been associated with the company for 22 years. **Silas McClure,** president since 1921, was elected to the chairmanship of the board of directors.

• **Roy C. Markle** has been appointed assistant comptroller, and **Richard G. Jones** assistant statistical supervisor, of U. S. Steel Corp. of Delaware, Pittsburgh. Mr. Markle was previously comptroller and assistant secretary for Carnegie-Illinois Steel Corp., a subsidiary. **Murrow D. Wells,** formerly assistant comptroller, succeeds Mr. Markle and **Ralph C. Grimm** has been appointed supervisor of financial statistics staff succeeding Mr. Jones.

• **William A. Kiley** has resigned as president of Thos. W. Kiley & Co., Inc., Brooklyn. **Mrs. K. Kiley Murphy** was elected president to fill the vacancy and **Edward J. Smith** has been made executive vice-president.

• **William A. Irvin,** former president of the U. S. Steel Corp., was elected a director of Willys-Overland Motors, Inc. Mr. Irving is still a director of the steel company and was its vice-chairman in 1938 and 1939.

• **Harold J. Siekmann** has been advanced to the position of chief engineer of the R. K. LeBlond Machine Tool Co., Cincinnati, to succeed **Wm. F. Groene,** who has retired as vice-president and chief engineer. Mr. Siekmann joined the LeBlond organization in 1910 and has been closely associated with Mr. Groene in the development of LeBlond products.

• **J. W. Frasche** has been named plant manager of the new tire factory in Miami, Oklahoma, of the B. F. Goodrich Co.

• **Larry F. Hardy** has been elected vice-president in charge of the home radio division of Philco Corp., Philadelphia. Mr. Hardy will be in charge of radio-phonographs, consoles, table models and small sets.

• **Frank J. Stanley** has been appointed plant manager of the Lebanon Steel Foundry, Lebanon, Pa., succeeding **Henry D. Phillips** who has resigned. For the past four years, Mr. Stanley has been plant superintendent. **L. G. Miller** assumes Mr. Stanley's former position.

• **George Ingersoll,** who was a sales representative for several years has been appointed district sales manager for the National Screw & Mfg. Co. in Cleveland and adjacent territory; **S. M. Washabaugh,** in the Philadelphia territory and **E. A. Derby** in the New York territory and the New England states.

• **Richard F. V. Stanton** has been appointed assistant manager of the machinery sales department of Niles-Bement-Pond Co., West Hartford, Conn. Mr. Stanton has been with Niles continuously since 1917 except for active war service in 1918. During the present war emergency he has been in charge of the company's outside contracting.

W. H. FELDMANN, president and general manager, Electric Machinery Mfg. Co.

HAROLD J. SIEKMANN, chief engineer, R. K. LeBlond Machine Tool Co.

RICHARD F. V. STANTON, assistant manager of the machinery sales department, Niles-Bement-Pond Co.

PAUL M. SNYDER, sales manager, Climax Molybdenum Co.

• **Paul M. Snyder** has been appointed sales manager of the Climax Molybdenum Co. His headquarters will be in Canton, Ohio. He joined the Climax Co. as a metallurgical engineer in March 1932 and has been in charge of the company's sales and development work in the Canton area since that time.

• **H. S. Gier** has returned to his post as Detroit district manager of Sharon Steel Corp. after 16 months' service in Army Ordnance. Mr. Gier has been with Sharon Steel for 23 years.

• **Arthur J. O'Leary** has been appointed assistant manager of sales of Lukens Steel Co., Coatesville, Pa., and **George W. Eshleman** has been made assistant to the manager of sales.

• **George L. Stewart,** who recently served as president of Steel Recovery Corp., has been appointed executive vice-president and member of the executive committee of Edgar T. Ward's Sons Co., Carnegie, Pa.

• **W. G. McFadden,** formerly assistant district sales manager of Allegheny Ludlum Steel Corp.'s Chicago office, has been appointed district manager of that territory.

• **William D. Turnbull,** who has been vice-president and sales manager of the Pomona Pump Co. of Cal., has been appointed manager of the Westinghouse Electric & Mfg. Co.'s agency and specialties department. He was formerly manager of the Westinghouse machinery electrification section.

• **William E. Miller** has been made general attorney in charge of Westinghouse Electric & Mfg. Co.'s law and patent department, Pittsburgh, Pa.

• **Charles W. France** has been appointed general manager of the Buffalo plants of Curtiss-Wright Corp. and **Burton H. Witherspoon** has been named general manager at St. Louis. Mr. France has been general manager at St. Louis for eight years, and Mr. Witherspoon has been executive assistant to Burdette S. Wright, vice-president in charge of the Curtiss-Wright Airplane Division.

• **Lloyd C. Smith,** whose career in the file industry dates back to 1912, has become associated with Heller Brothers Co., Newark, N. J., in a sales capacity. Mr. Smith resigned as sales representative in the New York area of the Nicholson File Co., Providence, R. I. He had held this post for the last seven years.

• **Nelson Bauer,** Newark district manager since 1929 of the Pyrene Mfg. Co. has been made assistant general sales manager; **Raymond F. Poole,** moves to Newark as district manager; **Frank R. Kachel,** succeeds Mr. Poole and **Truman Young** assumes the responsibilities of advertising manager.

• **Herbert A. Reece** has been elected first vice-president in charge of operations for the Meehanite Metal Corp., Pittsburgh. Mr. Reece joined the Meehanite Metal Corp. in 1929, and has served successively with this company as metallurgist, chief metallurgist, assistant to the president and manager of the corporation.

HERBERT A. REECE, first vice-president in charge of operations for the Meehanite Metal Corp.

• **H. C. Allington** has been appointed sales research engineer of Wickwire Spencer Steel Co., New York.

OBITUARY...

• **Fred W. Lemke,** 68, vice-president and superintendent of the Quality Aluminum Casting Co., Waukesha, Wis., died Feb. 16.

• **Frank E. Doherty,** former Wisconsin divisional sales manager for the Toledo Steel Co. at Milwaukee, died Feb. 17, after a year's illness.

• **Ellis J. Gittins,** 77 years of age, chairman of the board of the J. I. Case Co., Racine, Wis., from 1920 to 1935; director of the Young Radiator Co. and the Racine Tool & Machine Co., died Feb. 18 at his home in Racine.

• **William J. Davis, Jr.,** 75, retired General Electric consulting transportation engineer, died Feb. 21 at Schenectady, N. Y., after a long illness.

• **James S. Edinburg,** president and treasurer of James S. Edinburg Co., Inc., Worcester, Mass., died recently.

• **Frank W. Iredell,** who until his retirement 20 years ago was New York manager of the C. & G. Cooper Co., now Cooper-Bessemer Co., Mount Vernon, Ohio, died Feb. 17. He was 87 years of age.

• **Walter S. Reed,** president of American Ore Reclamation Co., American Sintering Co. and Buffalo Sintering Corp., died Feb. 4 at his home in Chicago. He was previously associated with Carnegie Steel Co., Pittsburgh and U. S. Steel Corp., New York, where he served as assistant to James Gayley, first vice-president.

• **John F. Conroy, Jr.,** founder and president of National Magnesium Corp., died Feb. 16 in Wilmington, Del. He was 49 years old.

• **James E. McDonald,** 53, general sales manager of the Edward Valve & Mfg. Co., Inc., East Chicago, Ind., died Feb. 25, after an illness of several months. Mr. McDonald first joined the Edward organization in 1917 and served as chief engineer and plant superintendent before becoming sales manager.

Fatigue Cracks . . . BY A. H. DIX

Soot-Seer

Page 80 of your Jan. 27 issue reads:

On Feb. 11 at Carbon City, capital of Nevada, Senator McCarran will preside. . . .

Are you trying to blacken the name of Nevada's capital city?

—Howard E. Long, Specification Engineer, Harrison Radiator Div., GM, Lockport, N. Y.

Our copy to the printer read "Carson City." As there is a subconscious urge at the root of every error, we had our print shop psychiatrist get busy. He finds that buried in the mind of the lino operator who set the "West Coast" Section that week was a fear that the success of the Senator's efforts to balkanize the steel industry would befoul Nevada's pure air.

Portside Drill

• • • If the lady operator in the now famous left hand drill cartoon had been standing beside a screw machine instead of a drill press the reverse flutes would have been grounds for no raised eyebrows. For left hand twist drills are being made, and in large quantities. Some of the older type multiple spindle screw machines, resurrected for war work, have half the number of spindles going counterclockwise, calling for left hand drills.

Even in the case of modern screw machines, where a left hand thread is to be tapped, the hole must necessarily be drilled with a left hand drill.

Paying Politeness

• • • Bob Blair, who is our business ambassador in most of Ohio, informs us of a gracious gesture made by the Cooper-Bessemer people, of Mount Vernon. Every visitor is handed a folder headed "Glad to see you, Mr. ....." It follows up with:

If this is your first visit, we hope it will be a pleasant one . . . and want you to feel right at home . . .

No matter how busy we are . . . we are glad to have you call and you will be interviewed as promptly and as courteously as possible.

In the folder is a list of Cooper-Bessemer key executives, who are committed by the folder to extend salesmen "the same courteous treatment we should like our own representatives to receive in other places of business."

The Golden Rule seems to be an ingredient of corporate longevity. Cooper-Bessemer was of voting age even when No. 1, Vol. 1, of your favorite family journal was printed, back in '55, and is now 111 years old.

It has always seemed to us to be good business to be nice to salesmen, not only because you get the benefit of it in a sellers' market like this one, but because every salesman is a traveling billboard not only for his own company but for all those on his beat. As salesmen are occupationally unreticent, a growing fund of goodwill is built up by having an army of them going around saying, "Even if I didn't sell the Blanks a nickel's worth of business I would still say they are nice people."

Good for One Gripe

• • • A highly successful executive of our acquaintance makes it known that instead of resenting criticisms he welcomes them. He thanks the critic and then says, "Your ability to see the faults in this implies that you have in the back of your mind a superior method. I want you to work on this and give me your recommendations."

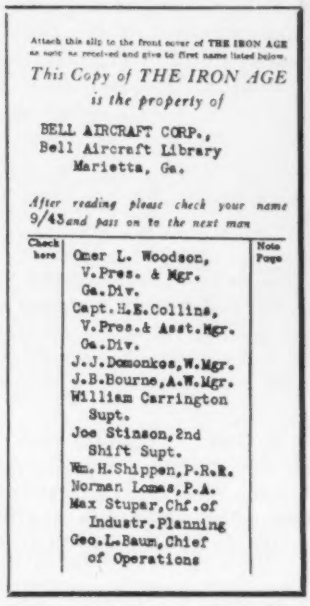
This sieves out gripes that have no visible means of support. It would be salutary if the idea of demanding a suggested cure as payment for the privilege of criticizing could be put on a national basis. Father of this thought is a poem by W. N. M., of the R. K. LeBlond Machine Tool Co., Cincinnati, in the current issue of that company's employees' magazine. We lift a few verses:

We criticize from dawn to dark . . .
A man from Mars would wonder
If everything our leaders do
Is one colossal blunder.

'Most any critic can tear down
A plan made by another,
But ask him for a better one
And lo, he has no other.

Wheelchair on Path of Knowledge

• • • The librarian of a large aircraft plant (not Bell Aircraft) boasted to us that he had on file THE IRON AGE and every other important technical journal bearing on aircraft manufacture. The information in them is, he said, available to all thirsters after knowledge in his plant.



Attach this slip to the front cover of THE IRON AGE as soon as received and give to first name listed below.

This Copy of THE IRON AGE is the property of

BELL AIRCRAFT CORP.,
Bell Aircraft Library
Marietta, Ga.

After reading please check your name 9/43 and pass on to the next man

We remarked to him that, while all thirst, many are able to endure the pain if the means for assuagement are not placed directly in their path. He should provide, we told him, a means of quenching thirst without requiring the thirster to detour, on the theory that the saloon on the direct route home from the shop sells the most beer. Being a discerning person, he agreed with us, and is now using the routing forms we sent him.

Resistance to the introduction of knowledge is reduced to the lowest possible point by the installation of a magazine routing system. About all the machinery such a system requires is a routing slip. And if you will send us a list of your readers we will send you a year's supply of slips free of charge.

Names That Sound Like the Job

Speaking of aptronymic doctors, how about your neighbor at 71 Park Ave., Dr. F. W. Splint, M.D.?

—T. V. Busk, Advertising Manager, Farrel-Birmingham Co., Ansonia, Conn.

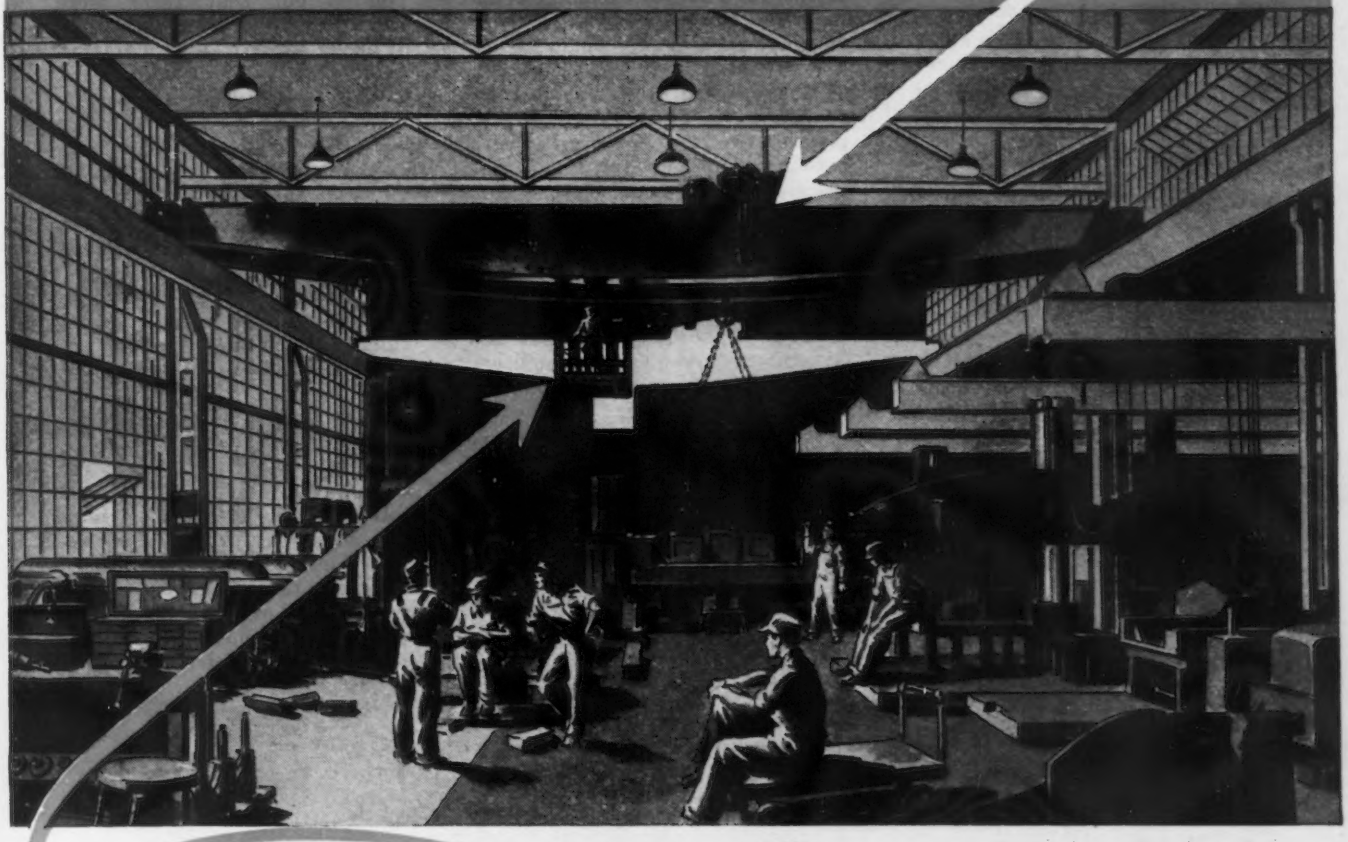
Not aptronymic but highly rhythmic is the name of our across-the-street neighbor, Klein, Hinds & Finke, accountants.

Puzzles

Last week's fly flew 300 miles.
Three minutes is all you get for this:

A butcher with a balance scale has occasion to weigh sales from one-half pound to sixty pounds. He must do this with five weights. What weights shall he use?

WAITING FOR THIS CRANE LOSES LOTS OF MAN HOURS



AN EXTRA Northern CRANE Would Save Them

Maybe they wait only a few minutes—but if they do it many times a day, plenty of man hours are lost—and you pay for them.

Moreover, the whole production schedule is slowed—time is lost everywhere—costing money and impeding your part of the war effort.

An extra Northern Crane on the runway will save all these countless minutes now being lost. Also, if you have an extra crane you need not fear breakdown—it won't tie up your shop.

Investigate the time saving possibilities of an extra crane.

Northern Cranes are fast, powerful, strong, have fine control. They are the fine machine tools of material handling.

Dear Editor:

COLORED STEEL SHEETS

Sir:

Sometime ago there was an article written, although the source of information is not available at the moment, to the effect that a steel company in the U. S. had experimented with putting colored pigment into steel and then rolling steel sheets of that color. Any information you may be able to give on this will be appreciated.

Our company has been receiving the "favorite family journal" for a number of years and the writer finds your articles quite interesting and educational, especially your editorials and "This Industrial Week."

J. S. WILKINSON,
Purchasing Agent
Western Steel Products Corp., Ltd.,
Winnipeg, Canada

● We know of no method of impregnating steel with color. The only way steel sheets can be colored is by painting, lacquering, electroplating, heat tinting or treating chemically.—Ed.

INEXPENSIVE PATENTS

Sir:

Not so many months from now the war-powered gears of our industrial machinery will suddenly cease grinding and peace and calm will reign again. The word "priorities" will disappear from the dictionary and perhaps rationing will be a short-lived necessity. The buying and spending urge will overtake most of us in order to obtain the many items denied us due to the allocation of critical materials to war-production needs. Billions of dollars will be spent after the war, provided, of course, that a critical unemployment condition does not develop, which can be averted if every industrial facility plans to produce something or engage in some sort of consumer service.

Many organizations have completed definite plans for post-war activities and know exactly what will be done at the "Go" signal. Many of these organizations will undertake even greater expansion programs after the war. But what about the typical "war-baby" and the "drop-in-the-bucket" size plants that enjoyed rapid, expansive growth but have not formulated post-war plans? Will they close down completely and go back to the "hole-in-the-wall" status or will they endeavor to retain their expansion and success by creating new products, materials or services?

Many of these organizations could carry on but perhaps they have no ideas for post-war activities. An idea contributed by some obscure inventor may tend to solve their problems.

That brings us to patents and and patent-procurement procedure.... If I were a Congressman, I would propose an amendment to the present patent laws which would make provisions for an easy, efficient, inexpensive but safe method whereby an inventor could place his ideas on the market immediately and be assured of proper protection. A federal agency could be set up for a period of years to operate a sort of exchange or meeting place for inventors and manufacturers. The service would be available for a moderate fee and the bulk of the operating costs could be defrayed by the manufacturers who make use of the service. The full patent procurement fees could be paid the Government in the event and at such time when an inventor were successful in selling his invention.

Industry depends to a great extent on the little ideas of insignificant individuals who will carry their precious ideas to their graves if the Government doesn't offer a solution to their problems. And the time to do it is right now.

WALTER G. TIEDEMANN
44 Stuart St.,
Lynbrook, N. Y.

CONTINUOUS CASTING

Sir:

Referring to the review of continuous casting presented by your Managing Editor, T. W. Lippert, on Feb. 23 at the 1944 annual meeting of the American Institute of Mining and Metallurgical Engineers, do you expect to reprint this paper or any of the other five related papers presented at the same session?

HUGH L. THOMPSON
Scovill Manufacturing Co.,
P.O. Box 1820,
Waterbury 91, Conn.

● The paper presented by Mr. Lippert was an abstract of the extensive article on direct casting appearing in The Iron Age of Feb. 24. This article is not a review of the papers presented at the Institute symposium, but rather is based on information independently obtained. Reprints of this article will soon be available. Doubtless the A.I.M.E., 29 West 39th St., New York, will reprint all the papers presented at the meeting.—Ed.

DYNAMIC HARDNESS TESTS

Sir:

The researches of Martel[1], Edwards and Willis[2], Herbert[3] and more recently that of Roudie[4] have demonstrated that the dynamic method for testing hardness offers a rich field for research.

It is pleasing, therefore, in these days of paper shortage to find you offering your readers such an extensive and illuminating paper as the one you recently published by E. Fetz on "Dynamic Hardness Tests at Elevated Temperatures." It is particularly gratifying to see research work being done with the dynamic or rebound tester, because as I have said elsewhere "the rebound principle has a great deal of merit when used in connection with the measurement of hardness. There is, however, a need for further investigation of the underlying principle."[5]

In a discussion following a symposium on hardness held by the A.S.T.M. at their last meeting, I pointed out that there were two classes of investigations on hardness, 1. those which took the instruments available and extended their applications. To this class belongs Mr. Fetz, who has applied the rebound principle to the measurement of hardness of a large variety of materials at elevated temperatures. It is just the sort of research which was asked for at the symposium discussion just mentioned. 2. The other class of investigator is interested in going back to the underlying principle or principles and asking whether they are being used properly. For instance, should the hardness be measured by the height of rebound of the hammer, depth of indentation made by the hammer, volume of the indentation, or what have you? So far as I can see both classes are equally important and merely depend upon our inclinations for research.

I wish to commend Mr. Fetz not only for his own contributions in the way of research, but for bringing together a lot of material which needed coordination. His review of Brenner and Kostron's work was particularly interesting and indicates one of the ways by which research on the underlying principles may be made.

I congratulate IRON AGE for publishing this fine article.

S. R. WILLIAMS,
Chief of Dept.

FONTANA MILL COST

Sir:

Can you tell me what is the cost to date of the Henry J. Kaiser steel mill at Fontana, Calif.?

K. C. PHELPS
307 Pacific Ave.,
Alameda, Cal.

● The total Reconstruction Finance Corp. loan to Kaiser for the Fontana plant is $109,805,000. Of this sum 90 per cent has been disbursed.—Ed.

THE FIRST 4 STAR FLAG IN OHIO

Monarch men and women accepted proudly the 4th Star for their Army-Navy "E" Flag, recently awarded them.

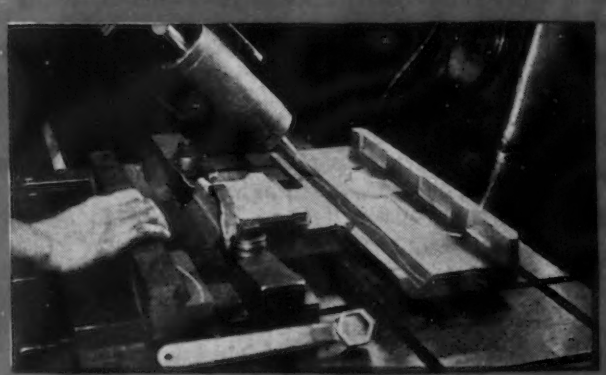
They have earned this recognition by their fidelity to the trust placed in them, when their first Navy "E" was awarded, November 11, 1941. They pledge "on time" deliveries of the lathes to which we are committed and of the other vital war material on which about 50% of our capacity is now engaged. They look forward to the day when their effort and our facilities (some of which are pictured here) may be put to full peacetime use, to help make more goods for more people, at lower cost.

THE MONARCH MACHINE TOOL COMPANY • SIDNEY, OHIO

MONARCH LATHES
Save Time

Motion pictures of operations, studied in detail, show where even slight savings can be made in time or material.

Utilization of floor space to the best advantage is reflected in our increased production per square foot of plant area.



When tools were hard to get, we designed and built our own, such as this device to mill oil groove in carriage.

Final assembly floor, from which we shipped a mile of lathes a month during our greatest production periods.

This Industrial Week . . .

- **Uniform Escalator Clause for Steel Contracts Effective**
- **CIO Proposal Would Put Government into Steel Business**
- **Production of Civilian Goods Problem in the Air Again**

TWO unusual developments affecting steel makers came to light this week as the industry pushed ahead full tilt against a mounting volume of orders created by invasion needs and other programs.

The establishment of a new Uniform Steel Contract Escalator Clause approved by the WPB and made effective March 1 on long-term and open-end contracts with procurement agencies has aroused much comment. The clause provides that when OPA ceilings are raised, contract prices also shall be raised but shall be subject to negotiation within a 60-day period. In some quarters it is said the clause may be a possible hurdle for the War Labor Board in trying to make a steel wage award.

More spectacular is a proposal by the CIO to put the government into the steel business through the operation of five blast furnaces which DPC has scheduled to close, and through subsidy of 20 small steel companies by means of below-ceiling prices on pig iron and scrap. This plan was reported proposed to WPB Chairman Donald M. Nelson last week by Philip Murray, head of the CIO.

Under Murray's plan, a commission of three persons, one from CIO, one from government, and one from industry, would direct the small steel operations. Companies participating would agree to regulation of executive salaries and dividend payments, among other things. Pig iron produced by the five furnaces would be sold to the small producers.

DESPITE the fact that steel operations have been strong (the national ingot rate this week is estimated at 97 per cent compared to last week's revised rate of 95.5 per cent), order backlogs still are on the increase. Sheets, plates, alloy steel, bars, and stainless are in particularly heavy demand, and even in the nail market a large inquiry for around 30,000 tons is current. Flat rolled steel demand remains intense.

Because orders are so greatly extended in certain lines, not too much credence is being placed in the far distant commitments, which may ultimately be revised if not wiped out entirely. Where quick deliveries are desired in heavily sought products, government officials obviously must decide which needs are most important.

WPB directives against the current month's sheet production are reported to have complicated schedules at certain flat rolled mills. Top urgency directives are being issued for 12 and 13 gage hot rolled, pickled and oiled material as a part of the new Ordnance packaging program, forcing current delivery promises back. Around 4.5 million tons of sheet and strip, much of which will go into special welded tubing, is understood to be required by the Ordnance program between now and June 30.

Alloy steel orders and inquiries are heavier. A very large tonnage of alloy strip was being quoted upon in the East last week in connection with a new military requirement.

Contrasted with probable first quarter production of 630,000 tons of tin mill products, output in the second quarter of this year is scheduled to reach 825,000 tons. It is expected electrolytic tin plate output in 1944 will be from 20 to 25 per cent of total tin mill production. Heavy production schedules for electrolytic are expected for the second and third quarters. Sometime before the year is out, a greater degree of standardization probably will materialize with respect to the tin coatings on electrolytic plate, using a minimum coating consistent with available supplies.

That insistent question—whether it is time to produce more civilian goods—seems to be in the air again apparently prompted by contract cutbacks, the run-down condition of civilian stocks, and the assistance given the railroads, farm equipment, container, and oil industries.

THE third annual report of the Truman committee points out that materials soon will have to be made available for further civilian production. Essential needs, says the report, are much greater than they were a year ago and continued curtailment of civilian output increases the threat of inflation.

"Once the requirements of the needs of the fighting forces are met, the Army and Navy can best be supported by strengthening the home economy," the Truman committee asserts. "The military has had trouble understanding this proposition."

Even before the Truman report came out recommending that wartime controls be lifted as rapidly as feasible, WPB had been strengthening its determination to give the green light to civilian production at the earliest possible opportunity, even at the risk of another controversy with military officials. Probably WPB will try to assign quotas and maintain some competitive position in such industries as the auto industry and household electrical goods fields.

Meanwhile, a survey of relaxations in WPB orders shows that while there have been more than 40 modifications of L and M orders since Jan. 1, the majority

Steel Market Briefs

• GENERAL—Production at, and in some cases above, former peaks. When some new slabbing and plate mills come in, more ingots will be used, and the ingot rate upped. Repairs may offset part of this expected increase. Despite heavy cancellations, orders still are somewhat ahead of shipments. Backlogs are still heavy. There may be minute signs of order volume having reached a peak recently. Changes abroad can affect this overnight.

• PRICES—Final word on OPA's decisions may not come as soon as expected. Too much optimism in some quarters. Adjustments on ingots, semi-finished, and rails seem certain. Other items expected to be adjusted but amount not now definitely known by either OPA or the industry. Labor will jump on any increases at all, and make hay even though adjustments cover cost accumulations since 1941.

• FLAT ROLLED—Plates still pushing out sheets on wide strip mills. Sheet deliveries are far extended, with companies making plates on wide strip mills. Tin plate going up to 825,000 tons in second quarter. Same or more for third quarter. Some of this increase to be at expense of sheet tonnage.

• COLD FINISHED BARS—Orders heavy. Army cutbacks more than offset by Navy increases. Army expected back in market in big way by July.

• ALLOYS—Total orders not spectacular, but flat rolled picking up. Latter offset by carbon flat rolled tonnage. Residual alloys in carbon steels substantial worry to carbon steel makers, whose carbon steels, especially bars, are relatively free from residuals.

• DELIVERIES — Mixed on all products. Tentative average deliveries—plates, August to October. Structurals, May to June. Sheets, third quarter and later. Bars, June and later. All of these promises could be changed substantially later in the year, depending on course of the war.

• MISCELLANEOUS—Shell steel demand to continue in second quarter on same basis as first quarter. Stainless steel demand increasing from food processing, dairy, oil refinery, and warehouse trade. Farm demand for wire products expected to increase 50 per cent this year over last year. Nail inquiries from Ordnance heavy. One reported at 30,000 tons, probably for packaging.

of these were granted for purposes other than to expedite civilian production.

John T. Whiting says the steel division is seriously concerned about the NE steel program. In December, 1943, 46 per cent of the alloy steel production was in the triple alloy NE grades, he said. In January, 1944, this proportion dropped to 40 per cent. It is the Steel Division's aim to see that 60 per cent of alloy steel output goes into the three-way alloys.

Increasingly, the problem of residuals in carbon steels is a matter of concern to certain steel makers, who discern potential competitive angles which might become important. As pointed out several weeks ago, the residuals are undesirable under certain circumstances. But under other conditions they might result in better performance of the carbon steel, hence giving the producer a sales advantage.

Republic Steel Corp. will begin this month and Carnegie-Illinois Steel Corp. will begin in April the production of landing craft armor plate. Great Lakes Steel Corp. has been turning out 95 per cent of the product up until the first of this month.

Simplification of procedures for disposing of idle or excess supplies has been effected. The expansion of Priority Regulation 13 also enables it to cover finished articles as well as industrial materials.

In this week's steel operations, output gains were made this week in Pittsburgh where operations rose one and a half points to 95.5 per cent; in Philadelphia, up half a point to 91.5 per cent; Cleveland, up half a point to 99.5; Wheeling, up one to 99; Detroit, up 13½ points to 99.5 per cent; and the Eastern District, up nine and a half to 101.5 per cent. Chicago operations declined half a point to 101.5 per cent and at St. Louis ingot output dropped two points to 92.5 per cent. Continuing unchanged are Youngstown at 98, Buffalo at 104.5, Birmingham at 99 and Cincinnati at 94.

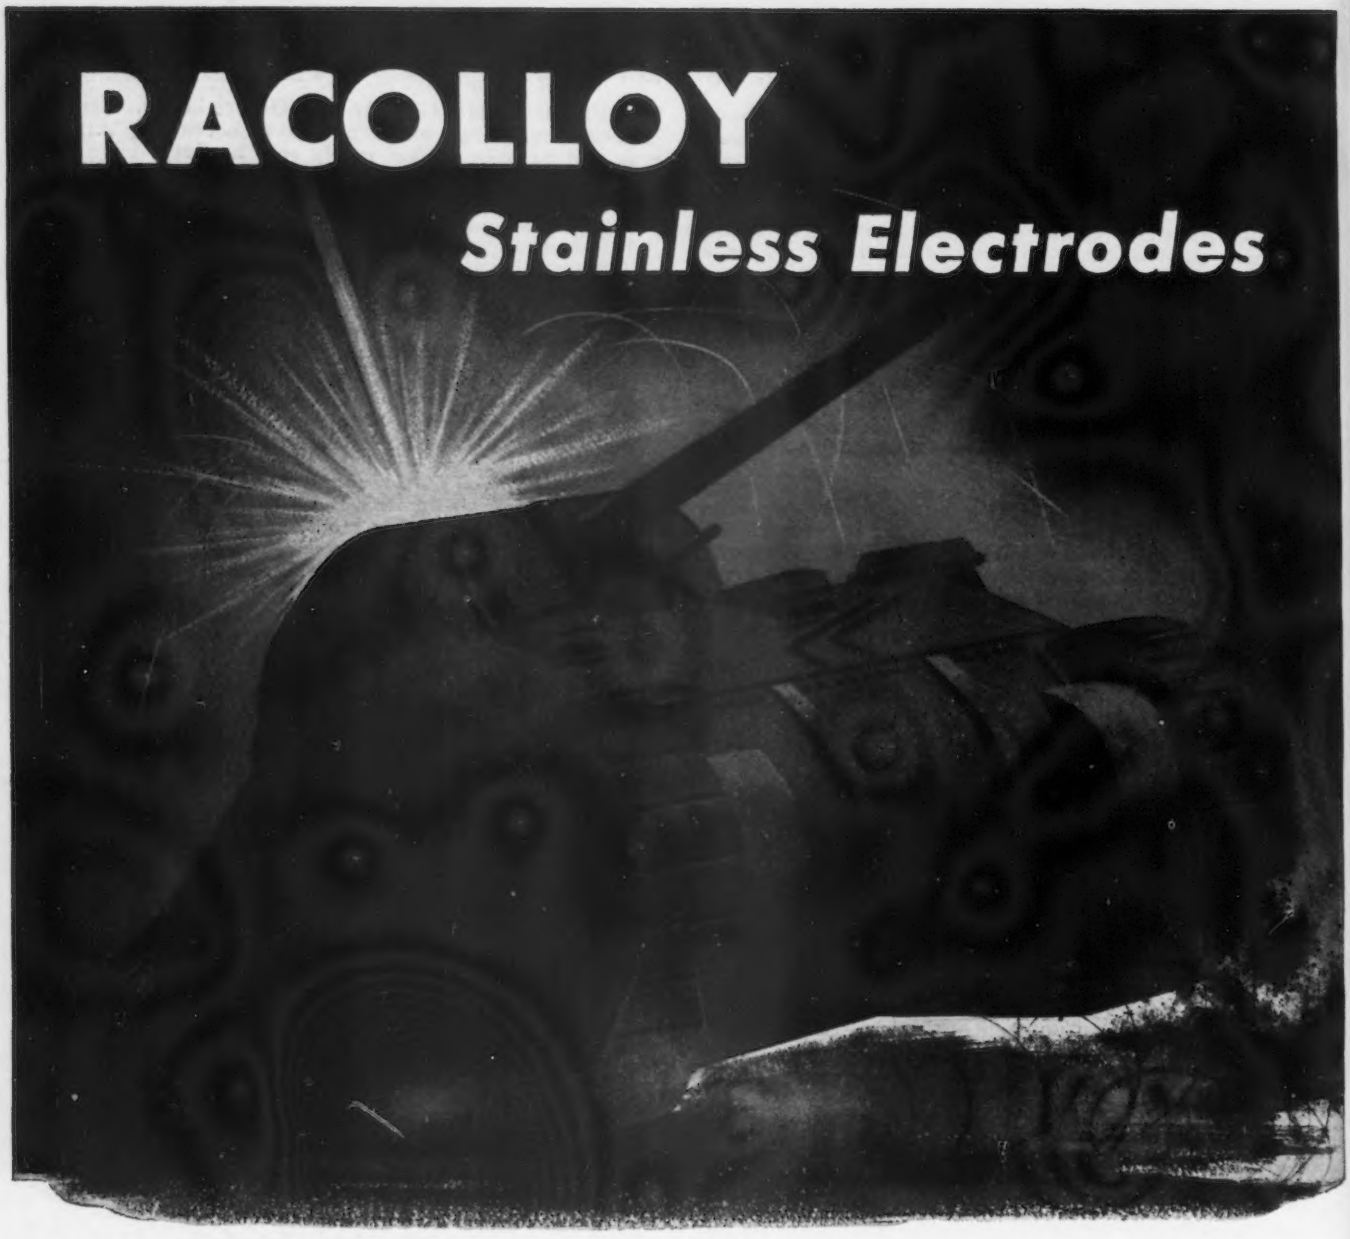
RACOLLOY
Stainless Electrodes



PROVE THEIR WORTH ON THE TOUGHEST JOBS

RACOLLOY 19-9

For the all-position welding of certain high-tensile, low-alloy, air-hardening steels, use Racolloy 19-9 Stainless Electrodes. The superiority of Racolloy 19-9, as of all Raco products, is assured by the most minute laboratory control throughout the entire production cycle.

RACOLLOY 19-9 Electrodes conform with Ordnance Specification AXS-886 . . . U. S. Navy Bureau of Ships Specification 46E4 (INT)—Grade V, Classes 1, 2 and 3

RACOLLOY 25-20

For the all-position welding of austenitic, corrosion and heat-resisting steels, use Racolloy 25-20 Scale-Resisting Shielded-Arc Electrodes. While specially designed for such work, they may be successfully used on high-tensile, low-alloy, air-hardening steels.

RACOLLOY 25-20 Electrodes conform with U. S. Navy Bureau of Ships Specification 46E4 (INT)—Grade IV, Classes 1, 2 and 3.

DUNDALK BALTIMORE 22 MARYLAND

New Steel Contract Escalator Clause May Be Obstacle for Wage Decision

Washington

• • • In the way of any wage award the War Labor Board may tie to the possibility of steel price increases, is the new uniform steel contract escalator clause approved by the WPB Procurement Policy Board recently. The clause became effective March 1 on all long-term and open-end contracts with procurement agencies, excluding contracts to be completed within three months.

The reason the new clause is said to be an insurmountable obstacle to such a WLB order, even if approved by Economic Stabilizer Vinson, is that such wage raises would in the end depend upon the result of negotiations between contracting officers and the mills and consequently would be fraught with uncertainty for both management and labor.

The new esclator clause provides that whenever OPA ceilings are raised, contract prices shall be raised, but shall be subject to negotiation within a 60-day period. The negotiation shall arrive at prices justified by the costs of the particular order of an individual mill and prices shall become effective on the date agreed upon.

In the event OPA lowers ceilings, contract prices must be lowered if higher than the ceiling. If contract prices are lower than the OPA price dip, or the same, then the original contract prices prevail until a new price is agreed upon by the mill and the contracting officer.

The text of the new clause follows:

"The contractor represents and warrants that the prices shown herein are not in excess of the maximum prices established by OPA or other authorized government agency, and in effect upon the date thereof for the supplies to be furnished hereunder. In the event such maximum price applicable to any item is increased, the price payable for any subsequent delivery of such item, made in accordance with the provisions of the contract, shall be increased by the same number of cents or fractions thereof, per unit, that such maximum price may be increased up to and including the date of delivery unless such price is redetermined as hereinafter provided. In the event such maximum price is decreased, the price payable for any deliveries made subsequent to the reduction shall not be changed (except that if such maximum price shall be below the contract price, the contract price shall be reduced to the maximum price) unless such price is redetermined as hereinafter provided. Within 60 days after the date of any change in such maximum price, the contractor, if required by the contracting officer so to do, shall furnish the contracting officer with such pertinent data as he may reasonably require showing the extent to which the factors causing such change are applicable to the supplies to be furnished. Any accounting data shall be that resulting from customary accounting practice in the industry. Upon the basis of such information the parties, by negotiation, shall redetermine the price applicable to such items, which redetermined price shall be effective from the date of the change in such maximum price until another change occurs in said maximum price. In the event of the failure of the parties to agree upon a redetermined price the contracting officer may terminate at the end of said 60-day period (and within 15 days thereafter) the right of the contractor to proceed with further deliveries of such item without liability upon either party except liability incurred with respect to items shipped or materials in process of manufacture prior to the date of termination. As used in this paragraph the expression 'material in process of manufacture'" shall be deemed to include only material which the contractor and the contracting officer shall agree has been fabricated or processed by the contractor of this contract to an extent which makes it unsuitable for the contractor's commercial inventory, and the government's liability with respect to such material in the event of termination pursuant to this paragraph shall include only an amount to be negotiated by the parties as reasonable compensation to the contractor for his expenses incurred prior to termination in acquiring, fabricating and processing such material and shall not include any allowance for profit or any compensation for commitments made or orders placed by the contractor.

CIO Offers Plan for Government to Operate Steel Plant Facilities

o o o

By DONALD BROWNE
Washington Staff

o o o

• • • **A new CIO plan** to put the government into the steel business through the operation of five blast furnaces DPC has scheduled to close down, and "subsidize" 20 small steel companies through below—OPA-pricing of pig-iron and scrap, was presented to WPB Chairman Donald M. Nelson by USW President Philip Murray last week.

The plan euphemistically called "Save Small Steel" insures CIO members jobs during the war and post-war period and would create a second steel division ("Small Steel Division") in WPB for the 20 small producers. The Commission would have three members—one from CIO, one from government, and another from the industry.

To participate, the 20 companies named would have to agree to: (1) submit entire cost of production figures; (2) that no executive officer shall receive total compensation that after taxes exceeds $25,000; (3) dividend payments to stockholders should not be above a reasonable level and (4) all outstanding federal laws and regulations affecting labor shall be obeyed.

The blast furnaces with location, management and annual capacity which would be run by their DPC agents according to the plan follow:

South Chicago, Ill.	
Republic Steel Corp...	**450,250**
Indiana Harbor, Ind.	
Inland Steel Co.....	**450,250**
Monessen, Pa.	
Pittsburgh Steel Co...	**432,100**
Daingerfield, Tex.	
Lone Star Steel Co...	**399,850**
Geneva, Utah	
United States Steel Corp.	**383,050**
Total	**2,115,500 Net Tons**

Under the plan the pig iron produced by these five furnaces would be sold to the small producers "who otherwise would not be competitive with the huge steel corporations." Murray reasoned that pig iron should be sold at that discount below the current OPA ceiling of $23 to $25 a ton as is found necessary to enable the small producers to be competitive but not less than the cost of production to DPC.

Battlefield scrap would also be sold by DPC to the small companies "which are not made competitive through the purchase of pig iron at below OPA ceiling prices."

Murray describes the plan as a "practical" one to keep 20 small steel firms in business, "preserve the livelihood of 27,175 steelworkers, prevent the deterioration of a dozen thriving communities into ghost steel towns, stop the further concentration of steel production in the huge steel corporations, and to save more than 5,678,000 tons of steel producing capacity for the continued prosecution of the war and for postwar use."

Pointing out that the war economy has pushed the price of scrap up to OPA ceiling prices (Now averaging $19) with a consequence that the small producers are unable to buy low cost scrap as they did in peacetime at $10 to $14 a ton, Murray said that the companies have had to

Total	5,678,000 (5.8% of Industry)	27,175 (5.3% of Steelworkers)	.94(1)	14 of 20 have OPA Price Relief, or 72 per cent of tonnage.	19 of 23 plants organized, or 88 per cent of wage-earners.

(1) Average weighted by number of wage-earners.
(2) Source: USW Research Dept.

buy more pig iron at prices $5 to $6 higher than scrap.

Murray found precedent for "subsidizing" the small semi-integrated producers' raw materials in the price exemptions OPA has granted 14 of the 20 companies. These price exemptions amount to a $5,754,000 "subsidy" based on a finished steel capacity of 2,877,000 tons with "the average price relief" of $2 a ton.

Also, the USW executive found that the workers of the small producers have "subsidized" the companies because geographical wage differentials produce a difference of 8c. an hour in the hourly wage of small companies and the rest of the industry—a straight time hourly earning of 94c. instead of $1.02.

The companies are confronted with "disaster and bankruptcy" as a result of wartime distortions of the economy, Mr. Murray said. He made the following contentions:

1. The price subsidy has been paid by the government through Lend-Lease and the several steel-consuming war contractors who have had to purchase the products of these firms at above OPA ceiling prices.

2. During the period of acute shortage of steel products of all kinds this form of government subsidy (price relief) served to keep these small producers in business. The steel buyers having no other source for steel products were compelled to pay above OPA ceiling prices to the semi-integrated steel producers.

3. Beginning in December, 1943, these conditions ceased to prevail. Acute shortage came to an end, and in several products a definite surplus developed, and as consequence consumers were no longer compelled to pay above OPA ceiling prices to semi-integrated producers.

4. The result has been that small producers have had to reduce prices to OPA ceilings, or lose business to "huge" steel corporations who can sell for ceiling prices.

5. Only the government can give assistance to these producers and as price relief is no longer effective in an easier steel market, must continue to give some assistance. (Save Small Steel Plan.)

6. Even the Treasury has turned from these small producers from whom it bought considerable lend-lease steel and is instead buying steel for lend-lease from the "huge" steel corporations who can sell at OPA ceilings.

Steel Enough for Millions of Pen Points On Long List of Excess Lend-Lease Material

Pittsburgh

• • • **Music wire** and pen point steel, both among the most expensive steel items made, are included in a 240-page list of lend-lease material available for sale by the Procurement Division of the United States Treasury Department. Practically all the material on this long list, which approximates 74,000 tons, is scattered throughout the United States. It is understood that this particular list is only one of several which have been circularized to possible buyers.

Of interest, possibly, to bus transportation systems, would be the listing of 49 carloads of bus bodies and one carload of bus body spare parts. The Treasury list does not go into detail on the type of bus mentioned.

Most of the steel bars and billets, which add up to about 30,000 tons, represent chrome silicon manganese shell steel of various sizes, most of which probably are not feasible for current shell requirements. The 400 tons of pen point steel, included in the listing of 24,612 tons of strip steel, seems, in the opinion of some steel people here, to be a substantial amount of such material and capable of producing "quite a few pen points." This material, which goes down to 0.01378-in. in thickness, and about 1.575-in. in width, running between 0.85—1.00 carbon, is available in coils, although some rumors in the trade have it that it may, in some quantities, have become rusted due to storage. The pen point steel may, in the opinion of some, have been ordered originally for military uses.

Of interest to wire drawers and piano manufacturers will be the 4,786 tons of music wire which is available.

On the particular treasury list in question are 237,600 gallons of various types of oil packed in steel drums. This includes such oil as crankcase, tank oil, lubricating oil, etc.

A summary of all the items in this single mailing of the Treasury Department is as follows: Steel bars and billets, 30,225 tons; chrome moly tubing, 17 tons; chrome moly sheets, 223 tons; strip steel (a large portion high carbon), 24,612 tons; music wire, 4786 tons; rope wire (the majority galvanized high tensile wire), 8220 tons; spring steel and high resistance wire, 3554 tons; galvanized staples, 1422 tons, or about 28,000 kegs; oil, 935 tons or 237,060 gal.; total, 73,994 tons of material.

This list, it is understood, which also included the 49 carloads of bus bodies, was circularized several weeks ago, and it is believed that further information desired by prospective buyers, who can fulfill the proper qualifications under the various WPB restrictions, can be obtained from R. J. Widmann, assistant to the director, Procurement Division, United States Treasury Department, Washington, D. C.

Examples of Steel Offered by WPB Offices

• • • Study of recent lists issued by WPB regional offices shows the following items, which are only a few of a great many offerings listed as being available in each of the 13 districts. These are the larger tonnages. Most of the individual items are in small quantities.

Colorado, Utah, Wyoming, New Mexico
(Regl. Office, Denver)

Flat bars—22,800 lb. 0.500 in. x 1¾ in. x 20 ft. (P-2001)
(List dated Feb. 26)

Eastern Pa., Va., Md., Del., So. N. J.
(Regl. Office, Philadelphia)

Cold rolled bars — 200,000 lb. 15/16 in. rd. WDX-1112 12/14 ft. (M-10-1)
Cold rolled bars — 434,000 lb. 1½ in. rd. EDX-1335 (M-10-3)
Hot rolled bars — 158,380 lb. 1 5/32 in. rd. spring gun quality (M-10-30)
Hot rolled strip — 149,667 lb. 0.083 x 6¾ in.; 22 ft. 11 in. (M-10-34)
(List dated Feb. 26)

New England States
(Regl. Office, Boston)

Steel plate—100,000 lb. 5/16 in. x 48 in. x 120 in. (EW-158)
Alloy strip, cold rolled—191,570 lb., 0.0897 x 5 5/16 x 46 13/16 in. (EX-1262)
Carbon steel flats — 400,000 lb. 3½ in. x 1¼ in. WD-1010 (MCX-1704)
(List dated Feb. 26)

Shipbuilders, Railroads, Jobbers Get More Steel in '43, Institute Reports

• • • **Increased shipments** of steel last year to the shipbuilding industry, the leading wartime consumer of steel, are shown in a preliminary consumption report by the American Iron and Steel Institute. The report covers shipments of 59,760,000 tons of semi-finished and finished products, based upon data received from about 125 companies accounting for about 95 per cent of total production.

Almost 11,433,000 tons of steel products were shipped in 1943 to naval and merchant vessel shipbuilders. That tonnage, which represented 19.1 per cent of total steel shipments in 1943, compares with 9,440,000 tons of steel delivered to the shipbuilding industry in 1942.

Contrasted with the increased deliveries to shipbuilders last year was a slight decline in the total tonnage going for such other war uses as ordnance, projectiles and tanks and for export to allied and friendly nations. The decline resulted chiefly from reductions in the Lend-Lease steel export program, which is covered under the heading "Miscellaneous industries and export." Nearly 14,158,000 tons, 23.7 per cent of the total, were shipped under that classification in 1943, against 14,848,000 tons in the preceding year.

A sharp decline appeared in shipments to construction industries. About 4,561,000 tons, 7.6 per cent of the total, were shipped to this field, compared with 8,660,000 tons in 1942.

Railroads received more steel in 1943 than in 1942. In 1943, more than 4,526,000 tons, 7.6 per cent of the total, went to railroads and car and locomotive builders, as against 4,318,000 tons in 1942.

The machinery and tool industries were shipped approximately the same tonnage in both years, 2,528,000 tons in 1943 and 2,540,000 tons in 1942. Nearly 3,574,000 tons were shipped to container manufacturers in 1943, compared with 3,666,000 tons in 1942.

Together the automotive and aircraft industries received 2,486,000 tons of steel in 1943 as against 2,122,000 tons in 1942. For both years, those tonnages exclude shipments of steel to manufacturers of forged and pressed, formed and stamped parts for the automotive and aircraft industries.

Steel jobbers, dealers and distributors were shipped 6,810,000 tons in 1943, compared with 5,962,000 tons in 1942. The tonnages going to other principal industrial classifications in 1943 were:

Steel converting and processing industries, 5,111,000 tons; pressing, forming and stamping industries, 2,484,000 tons; agricultural industry including equipment and implement manufacturers, 713,000 tons; oil, gas and mining industries, 1,378,000 tons.

Classification of Billings by Consuming Industries

	Net Tons
1. Steel Converting and Processing Industries	
(a) Wire drawers and wire product mfrs.	695,628
(b) Bolt, nut, and rivet manufacturers	1,096,801
(c) Forging manufacturers	
(1) Automotive and aircraft	605,588
(2) All other	900,454
(d) All other steel plants and foundries	1,812,209
Total	5,110,680
2. Jobbers, Dealers and Distributors	
(a) Oil and natural gas industry	358,166
(b) All other	6,451,372
Total	6,809,538
3. Construction Industry	
(a) Public (municipal, state, national)	84,020
(b) Highways	135,629
(c) Railways	71,717
(d) Automotive and aircraft	215,577
(e) Utilities	223,465
(f) Bldg. trim, accessories and builders' hdwe.	297,689
(g) All other	3,533,223
Total	4,561,320
4. Shipbuilding Industry	11,432,813
5. Pressing, Forming and Stamping Industry	
(a) Metal furniture and office equipment	128,001
(b) Hardware and household equipment	294,726
(c) Automotive	1,222,539
(d) All other	838,857
Total	2,484,123
6. Container Industry	
(a) Oil and natural gas industry	501,116
(b) All other	3,072,460
Total	3,573,576
7. Agricultural, Incl. Impl. & Equip. Mfrs.	713,028
8. Machinery and Tools	
(a) Machinery and tools, not incl. elect. equip.	1,742,802
(b) Electrical machinery and equipment	784,740
Total	2,527,542
9. Automotive and Aircraft Industry	2,485,643
10. Railroad Industry	
(a) All railroads	3,189,875
(b) Car and loco. builders and parts mfrs.	1,336,131
Total	4,526,006
11. Oil, Natural Gas and Mining Industry	
(a) Oil and natural gas, incl pipe lines	1,178,450
(b) Mining, quarrying and lumbering	204,772
Total	1,378,222
12. Miscellaneous Industries and Export	14,157,987
13. Total (Items 1 to 12)	59,760,453

WPB and OPA Form Two New Advisory Committees

• • • **The Office of** Industry Advisory Committees of WPB on March 3 announced the formation of the Metal Cutting Hack and Band Saw Industry Advisory Committee. William C. Teare, Tools Division, has been appointed the government presiding officer. Members of the committee are:

H. G. Aldridge, Huther Bros., Rochester, N. Y.; Jacob S. Disston, Henry Disston & Sons Co., Philadelphia; R. F. Ellis, E. C. Atkins & Co., Indianapolis; J. H. Flavell, W. O. Barnes Co., Inc., Detroit; William J. Greene, L. S. Starrett Co., Athol, Mass.; Ralph K. Lawrence, Simonds Saw & Steel Co., Fitchburg, Mass.; Donald McQuillan, Spartan Saw Works, Springfield, Mass.; Daniel K. Northup, Henry G. Thompson & Son Co., New Haven, Conn.; Verne Olson, Contour Saws, Inc., Des Plaines, Ill.; Phillip Rogers, Millers Falls Co., Greenfield, Mass.

The appointment of an industry committee of 12 representatives of firms engaged in the production of prefabricated farm structures was announced by the OPA. Those appointed to the committee are:

R. D. Hunting, Green Gable Builders, Cedar Rapids, Iowa; Ivon R. Ford, Ivon R. Ford Lumber Co., McDonough, N. Y.; W. L. Krapp, National Ideal Co., Toledo; John Alexander, Jr., Alexander Lumber Co., Aurora, Ill.; C. W. Gamble, Boise Payette Lumber Co., Boise, Idaho; Homer F. Prakel, George H. Wortch Lumber Co., Versailles, Ohio; Clifford M. Hill, GBH Way Homes, Inc., Walnut, Ill.; Tom Godwin, G. F. Mfg. Co., Exira, Iowa; Myron K. Pederson, Super-Structures, Inc., Albert Lea, Minn.; S. Lamar Forrest, Forrest Lumber Co., Lamesa, Tex.; Glen R. Newton, Glen Newton Lumber Co., Nevada, Idaho; Frederick L. Dill, Dain and Dill, Inc., Lake Mahopac, N. Y.

The newly appointed OPA advisory committee for makers of cast iron soil pipe and fittings includes:

Charles Hamilton, president, Alabama Pipe Co., Anniston, Ala.; William H. Deyo, president, Anniston Foundry Co., Anniston, Ala.; J. J. Crotty, vice-president, Central Foundry Co., New York; B. W. Frederick, vice-president, Eastern Foundry Co., Boyertown, Pa.; George H. Clay, president, Clay and Bailey Mfg. Co., Kansas City, Mo.; and Deems W. Hallman, production manager, Hajoca Corp., Lansdale, Pa.

Part of Cleveland-Cliffs ore fleet upbound in Whitefish Bay night of April 5, 1941.

Early Opening of Navigation and Enlarged Fleet Expected to Permit 90,000,000 Ton Ore Movement

Cleveland

• • • **Great Lakes** vessel operators whose responsibility it is to move 90,000,000 gross tons of iron ore this season, predict that a possible opening for full fleet movement this season may be as early as April 1. Such an opening would start the season off with a 19-day lead over last year's beginning.

In addition to moving 90,000,000 gross tons of ore the shippers also anticipate a movement of about 53,500,000 net tons of coal as contrasted with about 52,000,000 tons last year. Of this about 47,500,000 tons will move on Lake Erie, an increase of 1,500,000 tons over last year, 4,000,000 tons on Lake Ontario, about the same as last year, and 2,000,000 tons on Lake Michigan, an anticipated increase of 500,000 tons over last season's haul.

The movement of limestone usually parallels that of ore but is not expected to increase greatly over the 16,580,400 net tons moved last season.

Last season's haul of 84,404,852 gross tons of iron ore will be increased easily if the season opens earlier. It is likely, depending upon the grain trade, that more Canadian vessels will be utilized in the ore trade this season. Also, all vessels built by the Maritime Commission will be in service for the entire season. Some were completed only a short time before shipping stopped last season.

After a late opening last year heavy fogs and inclement weather held up shipments to such an extent that ore tonnage was nearly 8,500,000 tons behind schedule by the first of May. Cumulatively, two months later on July 1, the lag had piled up to 9,158,000 tons behind schedule. Improved weather in July and August brought on the movement of 27,500,000 gross tons in the two-month period, breaking the shipping record for all times for the same period by 1,000,000 tons. In the 123 days from July through October of 1943, a total of 52,000,000 gross tons of ore was moved, showing that the bulk of the movement was concentrated at the end of the season. Excessive steaming of ore is reported to have caused an average unloading delay of 4½ hr. for the season. The 1943 season totalled only 248 days as compared with 261 days for 1942.

Ice conditions which are the real criterion of the season's opening are reported generally as being much improved over the same time last year. Ice thicknesses are reported not more than one half to one third that of previous seasons and many parts of the lakes are considered open.

The United States Coast Guard Station here reports ice in the Duluth harbor of from 12 to 19 in. with the waters outside clear almost to Whitefish Bay. Last year at this time the ice outside the harbor was about two feet thick.

Earliest movements in past years show that ore from Escanaba came through the Straits of Mackinac on the following dates: April 20, 1940; April 3, 1941; March 23, 1942; and April 9, 1943. However, only a very small part of total ore shipments comes from this port.

•

Buffalo

• • • **Unmistakable** signs of an early opening of Lake Erie navigation have appeared along the Buffalo harbor front. Some owners already have placed engineers aboard ore carriers and fitting-out crews are expected aboard several other vessels next weekend.

Ice outside the harbor breakwall is about 8 in. thick compared with 15 in. on March 1 last year. There is virtually no ice inside the breakwall.

Navigation started at Buffalo last year on April 21. There are good prospects it will get under way 30 days earlier this year.

•

Washington

• • • **To permit** the unrestricted movement of coal on the Great Lakes until the iron ore traffic reaches its full stride for the 1944 season, ODT has temporarily suspended certain restrictions intended to give preferential treatment to ore cargoes. Suspension Order ODT 9A-1 suspends until May 15 all restrictions on coal movements on the Lakes.

"Steel Shortage" Committee Urges Western "Alloy Steel Pilot Plant"

Washington

• • • **The two-year-old Boykin** (House) "Steel Shortage" Committee continued on March 3 its sectionalistic hobby of wasting public funds in further hearings in search of voters' support for appropriations to finance metallurgical "will-o-the-wisps" as contrasted with sound economic development of resources of the country, regardless of geographical sections.

Indications are that if the committee were given its way, OPA couldn't furnish enough brown ration stamps to purchase the political pork with which the South and the West would be flooded, nor would the new surplus property administrator, William L. Clayton, ever be able to quit his job.

Completely insulated against the fact that the end of the war will find this country with perhaps as much as 40 per cent excess steel capacity and 20,000,000 tons of unfabricated inventory, the committee listened to proposals for utilization of West Coast ores and the construction of a "$750,000 alloy steel pilot plant."

Totally ignoring the fact that WPB has declared nearly all ferro-alloys to be allocation free, the committee has fostered the spending of $1,000,000 in the past year on mineralogical surveys in low-grade, high-cost chromium and in manganese. The committee is inferentially urging the spending of more money on metal producing facilities in face of the fact that WPB has within the last three months cut the steel expansion program back $140,476,000, mainly in alloy steel companies.

Director of the Bureau of Mines, R. R. Sayers, testified that the "direct" or sponge iron development financed by the government early in 1943 at the Warren, Ohio, works of the Republic Steel Corp. would cost $1,000,000.

This experiment sponsored by the committee and approved by WPB will be finished on April 15, according to chairman Boykin, or more than nine months later than WPB said the project would be completed. Moreover, the original estimate submitted to WPB by the committee as to cost of the project was for only $500,000.

The extinct "Pittsburgh plus" system was keel-hauled by committee members and Bureau of Mines witnesses. Leading the hackneyed political tirade against this system which no longer exists, was Representative Welch, Democrat of California.

A Bureau of Mines metallurgist said that deposits of chromium, manganese, and magnetite had been uncovered in many California counties, including Shasta, San Bernardino and Lassen. The work in Shasta county is still going on. One of the deposits is believed to hold 1,600,000 tons of concentrated magnetite.

This witness criticized eastern metallurgical processes, which he contended were being used in other parts of the country with little success. He advocated using procedures which have been tried experimentally in the Bureau to fit the needs of ores in whatever locality they might be unearthed.

Objections Raised to Foreign Allocations of Farming Equipment

Washington

• • • **Representative Calvin D. Johnson** (R. of Ill.) who thinks the American people are "being taken for the damnedest financial sled ride the world has ever known," on March 3 vigorously attacked the U.N.R.R.A. program calling for the distribution of some 500,000 items of farm machinery among 12 European countries that are wholly or in part Axis-controlled. Each of these items, he said, represents an essential and necessary piece of machinery for which American farmers have been pleading ever since Pearl Harbor. Mr. Johnson said that the nation's Capital "had become the headquarters for the 'Order of the Empty Satchel' where delegates assembled in answer to urging of starry-eyed globats who coursed the world, making lush and ridiculous promises of American goods and American dollars."

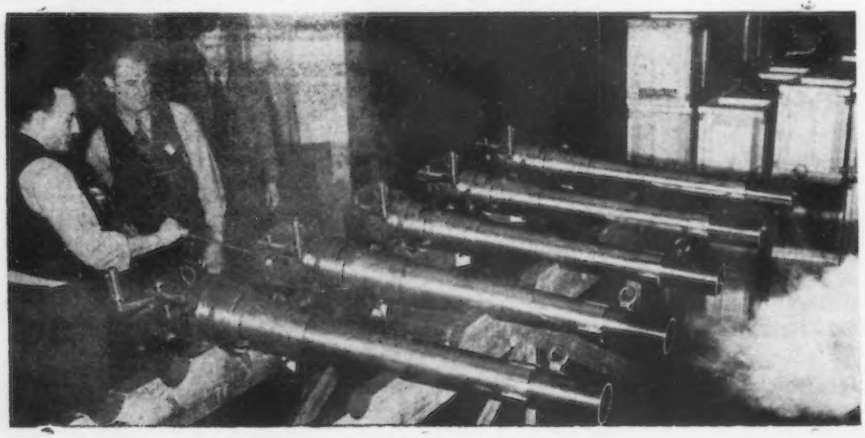
Representative Johnson said that there was no objection to the allocation of war materials to any nation that is actually engaged in war, but he did protest against this country playing "the role of Santa Claus to the entire world, forgetful of the American taxpayers who, for generations to come, will pay with sweat and sacrifice for this folly."

U.N.R.R.A. was referred to as the brain child of crystal gazers "whose heads are in the clouds and whose hands are in our pockets." Mr. Johnson inquired how much longer are the American people to follow, "as gullible children, these crystal-gazing Pied Pipers who lead us onward toward bankruptcy?"

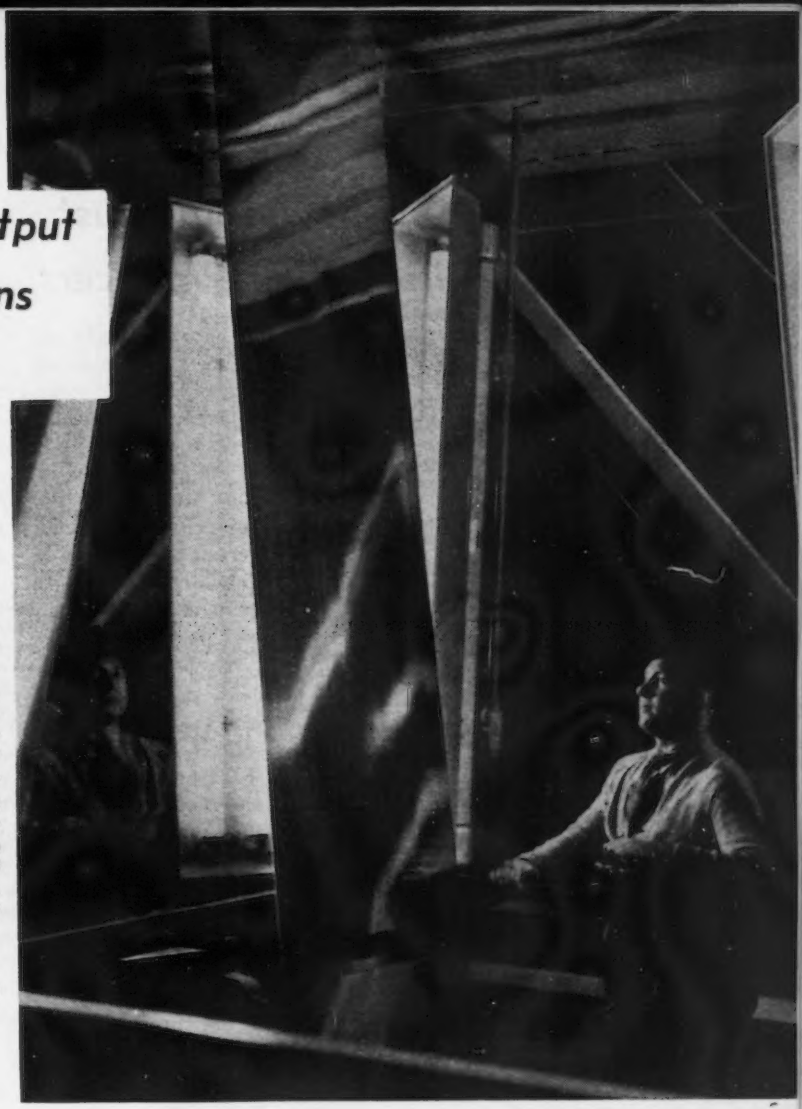
The Illinois representative submitted a detailed table showing the U.N.R.R.A. program for shipping farm equipment to European countries.

"Thirty thousand separators, 50,000 mowers, 17,000 reapers, 22,900 horse-drawn hay rakes, 40,000 harrows and harrow-sections, and 12,000 binders, every item of which members of Congress have endeavored to obtain for needy farmers.

FIRE TESTER: *Fisher Body Div. of General Motors Corp. is producing a 5-in. naval gun test mechanism which checks the kick, rammer and firing of the cannon without actually firing the weapon. The apparatus substitutes compressed air to simulate conditions resulting from actual discharge of the gun. Four Fisher plants in Michigan are doing the job.*



Second Quarter Tin Mill Output Likely to Be 200,000 Tons Above First Quarter



SHINY NEW PLATE: *The mirror-like finish on electrolytically coated tin plate reflects the image of an inspector as it emerges from a line at the Irvin Works of Carnegie-Illinois Steel Corp.*

Pittsburgh

• • • **Expanded** Lend-Lease Requirements, revisions in Order M-81, and permission to again produce crown caps from new tin mill products, will make possible a production of 825,000 tons of tin mill products in the second quarter of this year. Previous estimates, which included expanded production because of beer cans for export, had been set at 750,000 tons. First quarter production of tin mill products will approximate 630,000 tons.

While some sources feel that third quarter production of tin mill items may fall below the second quarter estimate, chances are that it may actually exceed this figure, although it is understood that third quarter production has been tentatively set at the same figure, namely, 825,000 tons. If the plate load decreases substantially by the third quarter, or even in the latter part of second quarter, as many believe it will, the competition on available rolling space on wide strip mills will be between sheet orders and tin mill products, where a choice has to be made. If past experience is any criterion, and if potential sheet orders are not on the very urgent list, with respect to direct war needs, tin plate and black plate probably will be favored.

An analysis of tin mill production during the period 1939 to and including 1943, statistically shows that tinplate, which had averaged about 90.5 per cent of total tin mill production in 1939, constituted 85.5 per cent in 1943. The participation of black plate, which was about 9.5 per cent in 1939, started to increase in 1941 when it constituted 11.5 per cent of tin mill production, to the point where in 1943 it represented 14.5 per cent. According to tin mill experts, however, the increase in 1941 was due to heavy shipments of black plate for tinning to Canada. In 1942 and 1943, black plate to Canada for tinning was also a factor, but the greatest item responsible for the increase in the percentage of black plate to total tin mill production was the restriction on the manufacture of tin plate.

On the basis of these qualifications, it appears that tin plate production is relatively stronger than ever, with respect to black plate, and with the further increase in electrolytic tin plate output, with much greater expansion looked for in the near future, tin plate output this year will regain its statistical position, and probably go beyond the 90.5 per cent of the total shown for 1939. The actual net cost difference between lacquered black plate and electrolytic tin plate for containers, in sanitary cans, is said to be so slight that the price advantage for using black plate is not great enough to hold down electrolytic tin plate uses.

It is expected electrolytic tin plate output in 1944 will be from 20 to 25 per cent of total tin mill production. Heavy production schedules for electrolytic are expected for the second and third quarters. Sometime before the year is out, a greater degree of standardization probably will materialize with respect to the tin coatings on electrolytic plate, using a minimum coating consistent with available supplies.

TIN MILL PRODUCTION TRENDS—1939-1943
Black Plate and Tin Plate

Source Material—Amer. Iron & Steel Inst.—Compilations—The Iron Age

IN NET TONS—(000 Omitted)

Year	Black Plate (N. T.)	% Total	Tin Plate (N. T.)	% Total	Total (N. T.)
1939	269	9.5	2562	90.5	2831
1940	283	9.5	2690	90.5	2973
1941	475	11.5*	3566	88.5	4040
1942	419	13.5*	2658	86.5	3077
1943	355	14.5*	2105	85.5	2460

*NOTE: Percentage figure may be misleading. Increase in 1941-42-43 due to (1) Black Plate exported for tinning, (2) restriction on Tin Plate. See story for detail, etc.

Triple Alloy Steel Output Must Increase, Whiting Tells Producers

Washington

• • • **In a letter** to all steel producers this week, John T. Whiting, director of the WPB Steel Division, pointed out that despite the easing in the steel supply situation, WPB will continue the economy program in the steel industry. The letter pertained directly to the NE steel production program, advising the industry to continue these melting schedules for the present. Reasons for this were explained in the letter to all steel producers which read:

"The NE steels were developed by industry and government metallurgists as a means of stretching available supplies of alloying elements to cover the enormous quantities of alloy steel needed in the war program. They have accomplished this purpose; whereas a year ago there were serious doubts as to whether the industry could meet the requirements of the Armed Services for alloy steel, these demands are now being satisfactorily met with the alloying elements available, and the situation is reasonably well in balance.

"We are seriously concerned, however, by the present apparent feeling of both producers and consumers that, in view of the easier alloy steel situation, the NE steel program can be relaxed. In December, 1943, 46 per cent of the alloy steel production was in the triple alloy grade. In January, 1944, this proportion dropped to 40 per cent. This tendency must be reversed to prevent the recurrence of an unbalanced condition of supply and demand that will interfere with the war program.

"It is our aim to see that 60 per cent of alloy steel production goes into the three-way alloys. This is essential for two reasons. The first is that the present supply-demand balance in alloying elements is based on the economies effected by the NE program. Any wholesale return to the single and double alloy steels would quickly and substantially increase the drain on nickel and chromium supplies and create a danger of the same shortages which led to the adoption of the three-way alloy steels.

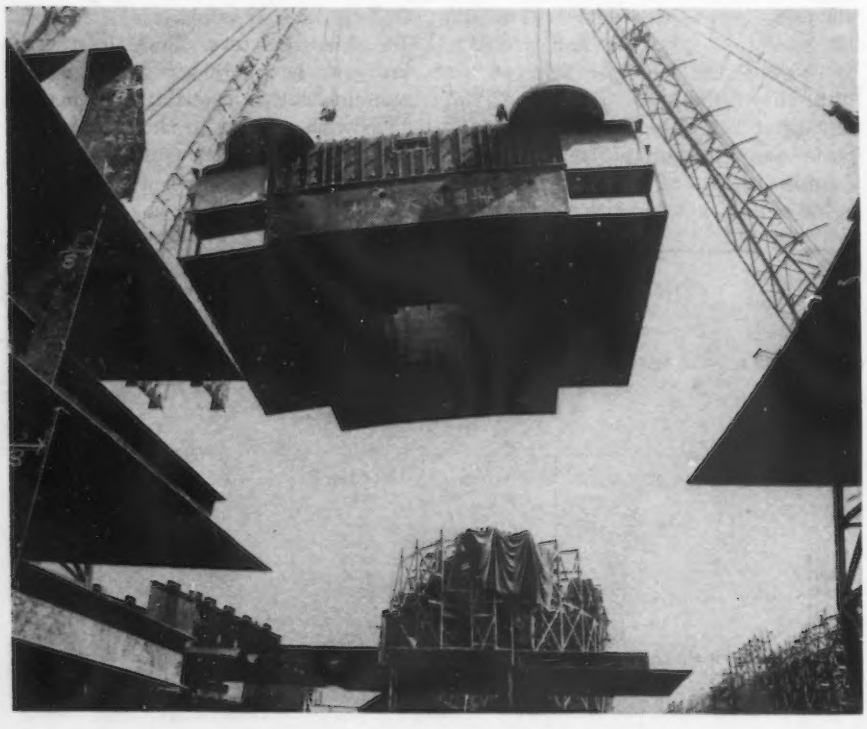
"In the second place, a substantial increase in the volume of single and double alloy steels would seriously threaten carbon steel production through shortage of carbon scrap, and possible contamination. Very considerable quantities of three-way alloy scrap, generated during the high production months of 1943, are still in the hands of manufacturers, steel producers, and scrap dealers. This scrap cannot be used in single and double alloy steel, but there must be provided an orderly channel through which it can move. To prevent immobilization for an indefinite period the logical movement is into more triple alloy steel. If some home cannot be found for it, it will unquestionably find its way into heats of carbon steel. Many of these heats would be summarily rejected and many others would cause troublesome, expensive and time-consuming difficulties to manufacturers who attempted to use them thus delaying production for essential war uses.

"Furthermore, a general return to single and double alloy steels will require, in addition to the virgin alloys, carbon steel scrap. But at the present time, supplies of carbon steel scrap are no more than adequate to support current production of carbon steel and none can be spared.

"For the above reasons, it is essential to keep the use of three-way alloy steels at a high level. In order to accomplish this, the Steel Division will, in cooperation with the agencies, review carefully all alloy steel melting schedules and will wherever possible make substitutions of three-way alloy steels for single and double alloy grades. This program has been fully discussed with the Armed Services; they are aware of the seriousness of the problem and have assured us of their cooperation. We ask the steel-producing and the steel-consuming industries to likewise cooperate to the fullest extent.

I shall appreciate it if you will send copies of this letter to your alloy steel customers, so that they too will be aware of the real importance of this program."

SUN YAT-SEN: *Here is the deck house for the 10,800-ton S.S. Sun Yat-sen named for China's famous patriot-statesman. The ship was launched by Mme. Wei Tao Ming at Marinship.*



Plans for Wooden Cargo Aircraft Given Up by WPB

• • • **Plans for** giant cargo aircraft of wood and plywood construction have been abandoned by WPB. An $18,000,000 contract awarded to the Kaiser Hughes Aircraft Corp. probably will be cancelled as a result of this decision. The contract was awarded the company in 1942, when aluminum and other metals were scarce. Today, lumber is believed in most quarters to be the most critical of the nation's materials.

Navy Adds to Armor Sources

Washington

• • • **The Republic Steel** Corp. will begin this month and the Carnegie-Illinois Steel Corp. will begin in April the production of landing craft armor plate. Announcement to this effect was made on Monday by WPB. Growing importance and expanded needs for this grade of protective steel resulted in the development of added sources, WPB said.

The special chemistry and typical heat-treating and quenching process required for this steel, it was pointed out, created a situation in which one company—the Great Lakes Steel Corp.—was turning out 95 per cent of the product up until the first of this month. Two-thirds of this total was heat-treated in the Great Lakes plant and one-third by the C. E. Atkins Co. Republic and Carnegie are among other companies that have developed such plates to meet specifications and have either acquired the proper heat-treating equipment or found plants with such facilities available to treat and quench their plate. There are also other potential producers, WPB stated.

The Navy's landing craft program which was initiated about a year ago called for special plate. But subsequent experience gained under battle conditions led to a revision of specifications on Oct. 1, 1943. Great Lakes turned out a type of armor plate that for chemistry, gage, and size best fitted into the Navy plans, so that company was given the bulk of contracts.

The WPB and the armed forces felt that it would be well to provide a margin of safety against any eventuality and not trust "all our eggs to one basket." Therefore, additional production sources have been developed.

Truman Report Examines Civilian Needs

• • • The third annual report of the Truman Committee praised industry, labor and Government for the success of the war production program (see also Washington comment, page 78). Among plants and companies singled out for commendation were the Irvin Works of Carnegie-Illinois Steel Corp. and the Aluminum Co. of America. The voluminous report contains a number of significant tables, several of which are shown below.

1944 Production and Requirements, Estimated by WPB

	War Items	Essential Civilian Items	Total War and Essential Civilian Items	Estimated Supply for 1944	Surplus or Deficit	Supply for 1938	1944 Supply Increased over 1938
Carbon Steel, tons	31,386,000	25,396,000	56,782,000	55,580,000	−1,202,000	32,402,102	1¾ times
Alloy Steel, tons	6,956,000	2,710,000	9,666,000	8,798,000	−868,000	1,653,510	5⅓ times
Copper, tons	2,864,000	3,378,000	3,236,000	3,385,000	+163,000	1,064,894	3⅛ times
Aluminum, lbs.	2,970,486,000	327,514,000	3,298,000,000	3,405,000,000	+107,000,000	286,882,000	12 times
Magnesium, lbs.	483,200,000	1,800,000	485,000,000	531,000,000	+46,000,000	5,434,000	98 times
Lead, tons			1,115,000	1,085,000	30,000	608,569	1¾ times
Zinc, tons			884,000	992,000	108,000	375,004	2¾ times

1939 Requirements Contrasted With Expected 1944 Production

Materials	Requirements for civilian use in 1939	Expected production in 1944	Excess of 1944 production over civilian use in 1939 (column 3 minus column 2)
Steel	36.5 million product tons	67 million product tons	30.5 million product tons
Copper	1,017 thousand short tons	3,590 thousand short tons	2,573 thousand short tons
Aluminum	350 million pounds	3,370 million pounds	3,020 million pounds
Magnesium	7.7 million pounds	531 million pounds	523.3 million pounds

Analysis of the Detroit Tool Sale (August, 1943)

Source and Government cost of cutting tools sold as steel material:	
Studebaker	$1,671,270.11
Nash-Kelvinator	47,598.29
Hudson	1,946.25
Chrysler	321.40
Total	$1,721,136.05
Represented purchasers and receipts:	
American Tool Supply Co., Detroit	$1,200.00
Ash Co., Detroit	2,700.00
Cadillac Surplus Co., Detroit	2,596.25
Gratiot Tool Supply Co., Detroit	26,533.00
George Maher Tool Co., Detroit	50.00
Progressive Industries, Detroit	227.24
Trylon Tool & Manufacturing Co., Detroit	50.00
United States Tool & Manufacturing Co., Detroit	125.00
Universal Aircraft, Detroit	2,533.00
Victory Machinery Exchange, Inc., New York	910.00
Total	$36,924.64
Difference	$1,684,211.41

Commercial Standards Set On Porcelain-Enameled Tanks

• • • **A commercial standard** for porcelain-enameled tanks for domestic use has been adopted, effective for new production from July 1, 1944. The standard was circulated on May 3, 1943, as a recommended standard, and sufficient numbers of manufacturers, distributors, and users to represent a satisfactory majority accepted the recommendations to establish them as Commercial Standard CS115-44 with the U. S. Department of Commerce, National Bureau of Standards.

The standard covers porcelain-enameled tanks for domestic use in sizes from 15 to 80 gal., inclusive for 300 lb. per sq. in. maximum hydrostatic test pressure. It sets general requirements on the base metal, enameling, operating conditions, types, sizes, and test pressures, as well as many other physical features of the products and methods of testing, labeling, and construction.

WPB Waives Restrictions On Tractor Repair Materials

Washington

• • • **Upon the request** of military procurement agencies, general restrictions on the annual quantity or dollar value of repair parts for track-laying tractors they may acquire have now been removed by WPB. However, the provision that limits military agencies to maximum purchases of 40 per cent by dollar volume of all shipments of critically short items made by manufacturers will remain in force.

Removal of restrictions has been accomplished by revoking that portion of L-53-b (subparagraph 3 of paragraph B) which formerly prohibited military agencies from acquiring more than 40 per cent by dollar volume of all shipments of track-laying tractor parts during the year ending June 30, 1944.

Study Shows Modifications of L and M Orders Haven't Aided Civilians Greatly

Cleveland

• • • **Through** the cooperation of the Cleveland WPB Regional Office, a survey of relaxation since the first of the year shows that while there were more than 40 modifications of L and M orders in the period the majority of these were granted for purposes other than to expedite civilian production. Rumors that some 65 orders were under consideration for an early relaxation in Washington have proved to be not entirely untrue but the same motive is seen behind the actions.

Latest information on the orders under consideration indicates that modifications are being studied and some re-drafting of the orders is underway but that these relaxations the same as those which have preceded since the first of the year are based upon eliminating substitute materials where material supply permits and conserving manpower involved in utilizing substitutes instead of the materials for which certain products were designed. Another smaller group of relaxations will be bred of urgent civilian needs which cannot be fulfilled otherwise.

The motive behind the relaxations to date and in the immediate future has been to make now non-critical materials more easily available in uses where substitutes have been required by former shortages; to aid in improving the quality and durability of products through the use of the proper material; and to conserve manpower by enabling manufacturers to use the materials and processing for which their products were designed and thus step up production with fewer man-hours. Improvement of quality and durability is also expected to increase the life of products and decrease the overall demand on a long range basis.

The modifications of restrictions are not only keyed to release additional material in limited quantities but also to control the flow of materials which may fall into excess categories. These purposes are being sought in the revisions but indications of an early return to enlarged essential civilian production are not yet present and it is pointed out that current modification moves should not be so construed.

A survey of L and M order modifications from the first of the year prepared for THE IRON AGE by the Cleveland Regional WPB Office reveals the nature of the relaxations to date and foreshadows what is to be expected in the immediate future. The following orders connected with the use of metals were considered in the survey:

L-216—(Schedule 4) **Rotary Files and Burs**—Increases manufacturers' quotas from a 10 per cent to a 25 per cent basis in relation to total file production.

L-72—**Razors and Blades**—Revocation makes amount of materials that can be obtained the only restriction on manufacture.

L-252—**Valves and Valve Parts**—Allows use of brass or bronze in making nuts for several valves.

L-30-a—**Kitchen, Household Articles (Galvanized and Non-Metal Coated Articles)**—Increase first quarter iron-steel quotas to 92½ per cent from 50 per cent of average quarterly usage in year ended June 30, 1941.

L-188—**Loose-leaf Metal Parts**—Metal allowance increased to 75 per cent of 1941 usage from 30 per cent.

L-32-b—**Metallic License Plates**—Permits manufacture of 1945 plates.

L-128—**Use of Chromium and Nickel in Automotive Valves**—Revocation allows use of prewar quantity in automotive intake and exhaust valves for civilian use.

L-152—**Baby Carriages**—Revocation permits use of prewar quantities of metal.

L-157—Schedule 7—**Wheelbarrows**—Manufacture of two more types for coal and coke handling permitted.

L-30-b—**Kitchen, Household Articles (Enameled Ware)**—Permits manufacture of three new items: drip coffee makers, teakettles and combinets.

L-126—Schedules 3 and 4—**Refrigeration Fittings**—Relaxes specifications on use of critical metals to allow these increases: copper strip, 300,000 lbs.; copper tubing, 660,000 lbs.; aluminum strip, 200,000 lbs.

M-24-c—**Iron and Steel Scrap**—Permits certain low alloy steel scrap to be used in carbon steel.

L-250—**Electric Motor Controllers**—Allows manufacturer to start production without obtaining AA-5 rating.

M-21-b-1—**Steel Warehouses and Dealers**—Relaxes restrictions on disposition of idle and excess inventories.

L-45—**Jewelry**—Allows use of 50 per cent more gold and palladium.

L-27—**Vending Machines**—Increases production to 75 per cent of prewar rate from 25 per cent.

M-24-c—**Iron and Steel Scrap**—Modifies segregation restrictions.

L-135—**Wood Upholstered Furniture**—Revocation plus amendment of L-260 allows use of quarterly use of 12½ per cent (dollar basis) as many metal springs as manufacturer used in 1941.

CMP-4—Revision eases rules for sale of copper, steel, and aluminum in controlled materials form.

L-193—**Conveying Machinery**—Permits use of some carbon steel in conveying and mechanical power transmission equipment.

Iron and Steel

M-21-h—Direction 1. Revoked.

M-21-g—Revoked.

M-21-a—Amended.

M-21-a—Direction for. Issued.

M-21-h—Amended.

These changes permit free use of alloys in tool steel.

L-211—Schedule 9—**Oil Country Tubular Goods**—Permits manufacture of lightweight tubing.

L-140-a—**Cutlery**—Removes minor restrictions on use of rivets and bolsters in cutlery.

L-30-d—**Cooking Utensils**—Authorizes production of 400,000 pressure canners by July 1.

M-126—**Iron and Steel Conservation**—Permits fabrication of certain civilian goods, including cigarette lighters, auto heaters, grease guns, hose reels, stencils, etc.

L-236—**Hardware Simplification**—Removes restrictions on use of metals in marine fittings hardware.

M-9—**Copper**—Allows users of small amounts of copper war materials to buy in any quarter materials containing up to 150 pounds of copper without authorization.

L-154—Schedule 2—**Steam Surface Condensers**—Removes restrictions on use of copper in manufacture of steam condenser tubes and tube sheets.

L-30-b—**Kitchen, Household Utensils (Enameled Ware)**—Authorized production of 500,000 cold pack canners by July 1.

L-106—**Copper**—Revocation makes available 5,000,000 pounds of copper per quarter for use in parts specified in L-158 (Automotive Replacement Parts).

M-6-b—**Nickel**—Relaxes "freeze" on nickel anodes, nickel salts and plating solutions in platers inventories.

L-190—**Scales**—Permits production of commercial scales for retail sale at 40 per cent of 1941 production.

L-42—**Radiator Supply Valves**—Removes many simplification and standardization features.

M-21—**Iron and Steel**—Cast iron soil pipe and fittings freed from all delivery restrictions.

L-318—**Spot Welding Electrodes**—Revocation removes standards for manufacture of all spot welding electrodes.

M-78—**Mercury**—Revocation removes restrictions.

M-21-d—**Corrosion and Heat-Resistant Chrome Steel**—Removes restrictions on utilization of steel mill facilities for fabrication of above steels.

Why Drive Against Japs Surges Forward

"• • • In five weeks I traveled 1200 miles through northern and eastern New Guinea and visited the Cape Gloucester area, and wherever I went I saw evidence of growing military might. . . . When you see equipment of all sorts stretched out for 1200 miles in areas that 12 months ago were tropical jungles, you get more than a little thrill. . . ."*—Lewis B. Sebring, Jr., in dispatch to New York Herald-Tribune.*

Distribution Curtailed on 22 Industrial Items by WPB Order

Washington

• • • **A new minimum preference** rating of AA-5 or better, designed to curtail distribution, has been established for 22 classes of industrial equipment. Previous requirement had been A-1-c or better. The classes of industrial equipment affected by the change in rating requirements, now covered by this amendment to L-123, include air filters, arc welding machines, baling presses, ceramic machinery and equipment, concrete products machinery, flexible metallic hose, tubing and fittings, oil filtering and re-refining machines, certain types of industrial ovens, paper shredders, pressure vessels (including air receivers), and wire working machinery, none of which was previously under this order.

The order also covers some additional sizes and kinds of compressors formerly under L-100; high pressure blowers formerly under L-163; heat exchangers formerly under L-172; pumps formerly under L-246; and fans and blowers formerly under L-280. A number of these kinds of equipment are also subject to General Scheduling Order M-293.

The amended order (L-123) no longer applies to conveying machinery and mechanical power transmission equipment, which are covered by L-193; portable (platform type) elevators and steel platforms, covered by L-287; safety switches and knife switches, covered by L-315; or circuit breakers, covered by L-300.

Deliveries of new equipment covered by the amended order cannot be made by manufacturers, distributors, dealers, or other persons except to fill orders rated AA-5 or better. The restriction also applies to deliveries from one department of an organization to another when the equipment becomes a component for incorporation into other machinery the organization may produce, or for installation and operation by such organization.

The restriction does not apply, however, when one department or branch of a company delivers equipment to another branch for eventual resale and for which a preference rating will be required. Such inter-departmental delivery would not constitute a transfer or change of ownership, but merely a physical change of position for the purpose of facilitating warehousing or delivery to eventual users.

Exceptions to the restrictions are allowed for various cases where deliveries are made in accordance with other regulations, or for certain specified transactions, such as:

Repair parts: Delivery of repair parts for any item. No complete item may be considered as a repair part and delivered under this exemption, even though it could be used as a component part of another item or of machinery not covered by this order.

Farm supplies: When items that are farm supplies under PR 19 are delivered in accordance with that regulation.

Petroleum industry item: When items used in the petroleum industry and covered by P-98-c are delivered in accordance with that order.

Items no longer needed: When an item is returned to the person from whom it was obtained, or when it can no longer be used for the purpose for which priorities assistance was given to help obtain it and the holder disposes of it in accordance with applicable provisions of PR 1 or 13.

Items ordered and put in transit before the restriction became applicable: The completion of delivery of items that had been placed in the hands of a common or contract carrier for shipment to the customer prior to the date upon which the restriction became applicable.

Certain orders rated below AA-5, but unfilled when restriction became applicable: Delivery to fill any rated order that was rated below AA-5 and could have been filled just before the date upon which the restriction became applicable without violating any WPB order, rule or regulation.

Deliveries of machinery not covered by this order: The delivery of new machinery, not covered by this order, into which an item has been incorporated as a necessary component part (or which is delivered in unassembled condition with an item which is a necessary component part, for assembly at the site of installation).

Used items: The delivery of any item that has been sold to a person acquiring it for use, and put into regular use by him.

Specific authorizations: Deliveries specifically authorized or directed by the WPB.

The replacement of a fractional horsepower electric motor or generator that is traded in when repair is needed: When a fractional horsepower electric motor or generator is delivered to a householder or other user solely for replacement of a used one that needs repair and the seller, in accordance with his regular business practice, takes the broken down or defective motor or generator in trade and repairs it or delivers it to another person who will repair it (whenever repair is practicable) so that it will be resold under similar conditions (or scraps it promptly when repair is impracticable).

No repairman or other person may deliver such an item unless he either complies with the foregoing conditions, or receives an AA-5 or better rating for the delivery for his customer, even though he has obtained the items under a regulation or order that assigns a rating for repair or maintenance purposes, such as the following: CMP Regulations 5, 5A, or 9A; or Orders L-79, P-126, or P-148.

This exemption permits a dealer not having repair facilities to deliver such a traded-in motor or generator, if it is repairable, to the manufacturer or some other supplier who will repair it or have it repaired within a reasonable time, and get one in exchange without an AA-5 or better rating. The manufacturer or other supplier who is asked to deliver a new item to a dealer in exchange for a used one is responsible for determining if the traded-in item is repairable.

Portable air compressors owned and used in a rental business: When portable air compressors owned by a person engaged in the business of renting them are leased by the owner. This exemption does not apply to the sale of a new item by such owner, or to the original purchase of the items by him.

This change of restrictions on delivery of these items is accomplished by the revocation of four Limitation Orders: L-100, L-172, L-246 and L-280 and by an amendment to L-123, which supersedes former Interpretations 1, 2 and 3 of the order, which are also revoked.

Priority Changes

L-83—Amended order removes the control over purchase and use of packaging and labeling machinery since control over this type of equipment is now covered by order L-332. (3-1-44)

L-123—Amended order establishes a new minimum preference rating of AA-5 or better for 22 classes of industrial equipment. Previous requirement had been A-1-c or better (3-4-44)

M-293—Int. 1 which clarified application of the Class Z product delivery date control procedure, has been revoked. (3-1-44)

M-293—Amended Table 8 removes all single phase power and distribution transformers having a capacity smaller than 250 kva., with a few exceptions, from scheduling and purchase order control. (2-28-44)

P-56—Amended order permits the use of a new and simplified application form under which operators of mines and smelters in the United States and foreign countries may get the materials and products they need to carry on their operations. (3-3-44)

Reg. 3, as revised, makes changes in the list of items which may be delivered without regard to preference ratings and in the list of items for the purchase of which blanket MRO preference ratings may not be used. (2-29-44)

Pig Iron Placed Under Transportation Control

• • • **When WPB** decided to discontinue allocations of pig iron it also decided to discontinue assigning priorties to purchases of this commodity. The producers have been notified, however, that pig iron will be subjected to a transportation control in order to eliminate cross hauling. Therefore, it has been added to Haulage Request TR-2. This notice has been sent all producers by J. T. Whiting, Director of the Steel Division. Whiting's letter reads:

"As you know, the total allocation of pig iron was discontinued as of Feb. 1, 1944. This was accomplished by amendment of order M-17. Under the amended order the WPB retains the right to issue special instructions with respect to production and delivery of pig iron. We hope that it will not be necessary to issue such instructions except in very unusual cases.

"The transportation savings which were brought about through the allocation procedure are as important today as they have been at any time during the last two and a half years and it is essential that these economies should not be lost. The responsibility for seeing that they are not lost now rests squarely with the individual pig iron producers. In order to assist them in maintaining these transportation savings, pig iron has recently been added to Haulage Request TR-2."

"Self-Help" Manpower Plan For Lake Carriers Approved by ODT

Washington

• • • **The ODT announced** on Monday its approval of a self-help program prepared by the Lake Vessel Committee, an organization of Great Lakes carriers transporting bulk commodities, aimed at centralization of Selective Service requests, employment stabilization, and recruitment. At the same time, in a letter sent to operators of tankers and car ferries and to interested unions, the ODT urged other branches of the industry to undertake similar self-help action.

Because of the extremely short time remaining before the opening of the season and the importance to the war effort of employment stabilization on the Lakes, the bulk carriers' plan was endorsed as an expedient, ODT officials explained. They said that attempts of the ODT, the Recruitment and Manning organization of the WSA and the WMC to bring all branches of the Great Lakes transportation together under a single industry-wide manpower stabilization program have been unsuccessful.

The ODT's letter to tanker companies, car ferry operators, and interested unions said that, while the committee's program does not include formal or informal arrangements with the RMO, the ODT would "view with equal approval" recruitment and manning arrangements which other branches of the industry might make with the RMO or, in the case of car ferries, the Railroad Retirement Board. The letter said further that, in the ODT's opinion, companies having contractual relations with labor unions should include unions in any self-help programs formulated.

The Lake Vessel Committee, acting as a central organization, plans to request deferments for seamen of member companies to avoid "confusing duplication by individual companies and to keep local boards more accurately informed of the manpower needs of the fleet." Deferments will be asked for licensed officers; seamen over 22 years of age certificated according to Federal law and employed in skilled ratings as able seamen (wheelsmen, watchmen, and deck watchmen), oilers and firemen; and pre-Pearl Harbor fathers over 26 years old with the rating of cook, tunnelman, and gateman.

Individual companies will continue recruitment through their own personnel offices, but the Lake Vessel Committee will coordinate and supplement their programs by group advertising, radio programs, and field representatives in the Great Lakes area.

According to the outlined plan, the committee will arrange with WMC regional and area officials for use of certificates of discharge or continuous discharge books as statements of availability for intra-industry job changes. For seamen seeking employment outside the Lake industries, the committee will ask that the central organization be permitted to issue statements of availability in place of the individual employers. Periodic reports on deferments, recruitments, and the general manpower situation will be made to the ODT, Selective Service and to the WMC under the plan.

Other Great Lakes carriers and the unions have been invited to meet with ODT officials in the near future to discuss plans of their own for recruitment and manning.

Marine Fittings

Washington

• • • **Restrictions on the** use of metals in the manufacture of marine fittings hardware were removed by the WPB through a revision of Schedule III to the hardware simplification order L-236.

The schedule, issued in October, 1943, covers forged, fabricated and pipe turnbuckles; forged shackles; rope thimbles; rope sockets; forged hoist, grab and slip hooks; cleats; and chocks. Simplified practices are established by restricting manufacture to the sizes and types listed in the schedule.

The principal effect of this latest action is to permit the use of alloy steel instead of carbon steel where necessary. Minor changes are also made in permitted sizes of some of the items.

Daily Plate Output Record

Washington

• • • **Setting a world record, American production of plates in the 29-day month of February was at the rate of 38,700 tons a day. Production for the month, according to the WPB Steel Division, was 1,122,219 tons. This compares with 1,072,001 tons produced in February, 1943.**

The previous record daily output was in January of this year with an average of 37,800 tons. The January total output was 1,173,000 tons.

Metals in Toys Urged

Washington

• • • **Return to use** of iron and steel in toys, in the opinion of members of the new Toy Industry Advisory Committee, would save manpower and critical materials and at the same time result in more serviceable, lower-cost products.

If iron and steel, now permitted to be employed only for joining hardware, could be used more freely, a large quantity of wood could be saved, and more serviceable toys could be manufactured.

Power Driven Tools

Washington

• • • **Because** western dealers in light power-driven tools are a greater distance from sources of supply, inventory provisions of the order governing these tools were amended by WPB. The action was taken through amendment to limitation order L-237.

The order previously provided that no supplier could accept delivery of any light power-driven tool which would increase his inventory of that size and type of tool beyond five. Under the revised order, the inventory limit is raised to eight tools of each size and type for dealers in 17 western states.

Form WPB-2752 For Welders

• • • **Applications for** the purchase of resistance welding equipment will continue to be accepted on form WPB-2752 only until March 15, 1944, WPB reported. After that date all such applications must be submitted on form WPB-1319. These forms have been valid since Feb. 16, 1944. This action is covered in an amendment to limitation order L-298.

Retracting and Repositioning Work Within .0002 OF AN INCH—By Push Button

The most frequently needed function in a precision boring machine is that of retracting the work to facilitate measuring and tool setting.

In the DeVlieg Jigmil, this function is automatic—by fingertip control. Operation of a push button unlocks the table and moves it by rapid traverse to the desired position for measuring. For repositioning, operation of a single push button will cause the table to return to its cutting position by rapid traverse, stopping and locking automatically. Uniformity of selected position for stopping and locking is dependable within .0002".

The DeVlieg Jigmil is a new type machine—has the spacing accuracy of a Jig Borer — Performance Qualities of a Milling Machine—Convenience and Flexibility of a Horizontal Boring Mill. All control is so centered and organized that the operator never has to take his eyes off the work.

Thus, the Jigmil fulfills the machine tool ideal—a powerful and accurate extension of the operator's hand.

Many machines show 75 per cent greater average daily productivity.

...PRE-WAR Success Story of *Grammes*

"PACKAGED METAL ENGINEERING"

FOR *Your* POST-WAR PRODUCT

Grammes "Packaged Metal Engineering" provides more than the efficient fabrication of metals—the scope of this valuable service ranges from Product Design Research to Controlled Distribution. This R.C.A. radio case is a typical *pre-war* achievement of functional design, coordinated engineering skill, economical precision production, and straight-line assembly methods. This *all-inclusive service* can help solve your problem of developing a post-war product or improving a present one.

Grammes mass-production facilities, comprehensive knowledge of metals and their fabrication, coupled with more than 69 years of "know-how" can save you money, time and materials. Although 100% in war work, our research, designing and engineering services are available for developing your idea or solving post-war production problems. The following under-one-roof manufacturing facilities offer a versatile and economical setup for producing and assembling metal parts into complete units, with precision control.

• STAMPING	• EMBOSSING	• SPRAYING
• DRAWING	• HARD ENAMELING	• HEAT TREATING
• SPINNING	• SCREW MACHINES	• PLATING
• WIRE FORMING	• DRILLING	• ENAMELING
• ETCHING	• WELDING	• TOOLS & DIES
• LITHOGRAPHING	• MACHINING	• LINE ASSEMBLY

Let's work on your post-war product. Complete confidence assured. Write Contract Service Dept. A-3 for booklet "Contract Service by Grammes."

Veterans' Employment Problems Analyzed

Pittsburgh

• • • **Management should treat** disabled veterans "as normal persons, which they always have been and will continue to be." Furthermore, irresponsible persons, discharged from the armed forces and employed in industry, must not be allowed to "cast a stigma" on all returned soldiers.

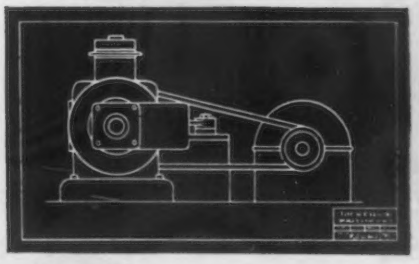
So cautions a special report on putting disabled veterans back to work, prepared by the Industrial Hygiene Foundation at Mellon Institute here. A panel of authorities who will supply practical information on "how to do it" to industry is prepared to function until the rehabilitation job is done. The panel is headed by Dr. C. D. Selby, medical consultant, General Motors Corp., Detroit. Other members are: Col. John H. Andrews, executive officer, Reemployment Division, National Selective Service System, Washington; Dr. Harley L. Krieger, medical director, Ford Motor Co., Detroit; A. A. Hendrix, personnel director, Eastern Aircraft Division, General Motors Corp., Linden, N. J., and I. Dent Jenkins, personnel manager, Harrison Radiator Division, General Motors Corp., Lockport, N. Y.

Efforts of industrial plants to meet this growing problem are discussed in the initial report of the Foundation. The Ford Motor Co., according to Dr. Krieger, has always attempted to hire 10 per cent of its employees from disabled workers, explaining "it is our impression that these men, knowing their disabilities, are less liable to accidents than normal workers because they will not take chances." Dr. Krieger says: "We are endeavoring to handle the rehabilitation of the returned soldier just as we would handle the employment and placement of any handicapped employee."

In order to carry this program out, Ford Motor Co. has divided returning soldiers with medical discharges into two groups, those who have not been overseas and those who have seen action abroad. The majority of discharges in the first group, it is said, are "for common, ordinary, every-day disabilities that do not amount to very much in industry." In the second group, however, Dr. Krieger said that jobs must be found for one armed men, one legged men, for one eyed men, and for men who have recovered from tropical diseases. The actual job placement at Ford Motor is made

Blueprinting

PROVIDES THE BEST OF ALL TRACING REPRODUCTION METHODS



FASTEST . . .

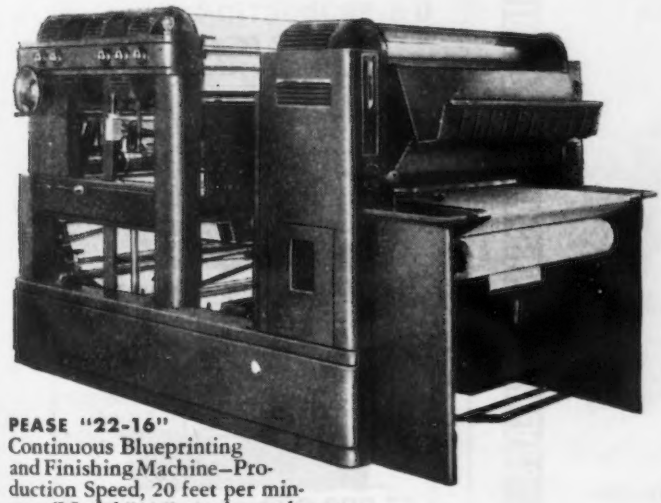
30 feet per minute actual production speed with Pease "22" Continuous Blueprinting and Finishing Machine (not shown) provides quality Blueprints in staggering quantities . . . ON TIME . . . NO WAITING.

LOWEST COST . . .

As low as a cent (and even less) per square foot of finished Blueprints with Pease Continuous Blueprinting and Finishing Machines . . . much higher with other tracing reproduction methods.

FINEST . . .

Blueprints—sharp white lines on deep blue backgrounds, virtually impervious to dirty finger marks. Blueline prints—sharp blue lines on clear white . . . Both easy to handle, lie flat, conserve filing space. Good Blueprints can be made from old, soiled, worn or torn tracings . . . impossible with other tracing reproduction methods.



PEASE "22-16" Continuous Blueprinting and Finishing Machine—Production Speed, 20 feet per minute. (Model "22," not shown, has a Production Speed of 30 feet per minute.)

EXCLUSIVE PEASE FEATURES . . .

- **Sliding "Vacuum-like" Contact** smooths out tracings, prevents errors in printing.
- **Three Speed Lamp Control** provides operation at 10, 15, or 20 amperes, minimizes running speed and dryer heat changes.
- **Actinic "No-Break" Arc Lamps** burn for 45 minutes without breaking arc, resume instantaneously.
- **Horizontal "Floating" Water Wash** floats prints free from tension and prevents wrinkles, stains, bleeding.
- **Quick Change Chemical Applicator System** very economically allows change from Blueprints to Negatives in 20 seconds.
- **Eight-inch Diameter Drying Drums,** thermostatically controlled, heated by gas or electricity, dry the prints "flat as hung wallpaper."

VERSATILITY . . .

Pease Continuous Blueprinting and Finishing Machines are not limited to making Blueprints alone. They also produce excellent Blueline prints, Brownprints and Brownline prints . . . together with a Wet Direct Process Developing Attachment they provide a splendid method of making Black and White prints continuously. . . Moreover, when used in conjunction with a dry direct process developing machine they afford a first rate system for making Whiteprints (dry direct process prints).

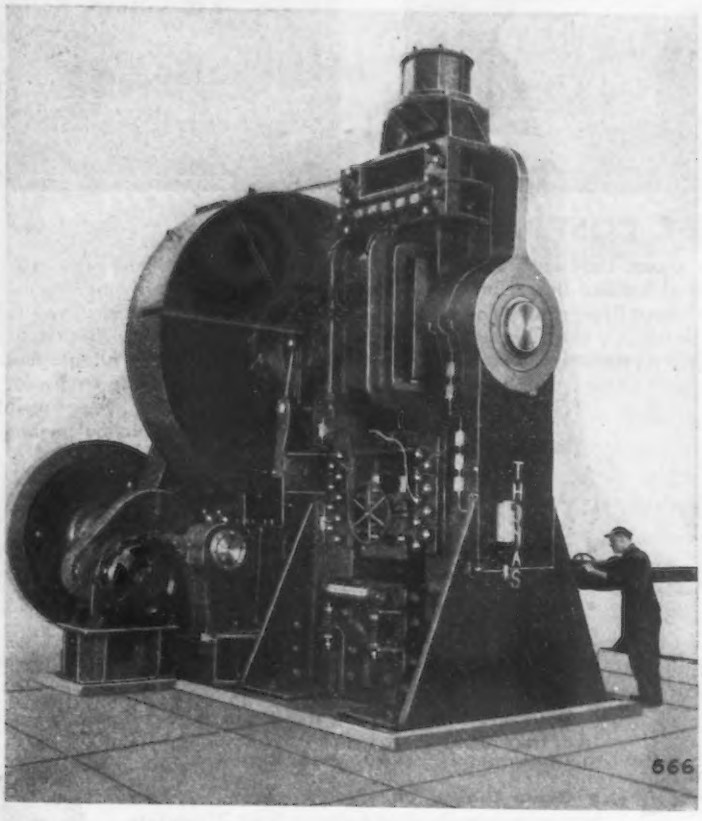
THOMAS BILLET-SHEARS



THOMAS Heavy Duty Billet Shears are of all steel construction, closed housing, guillotine type for strength and rigidity. If desired, a 12-foot power-operated reversing feed table is available for use in connection with these shears. Tables are of same sturdy construction as the shears, and come with cast rollers, mounted in roller bearing pillow blocks. Entire table is spring mounted, so that material can be carried through the shear clear of the blades yet depress sufficiently when cut is made.

THOMAS MACHINE MANUFACTURING COMPANY

PITTSBURGH, PA.

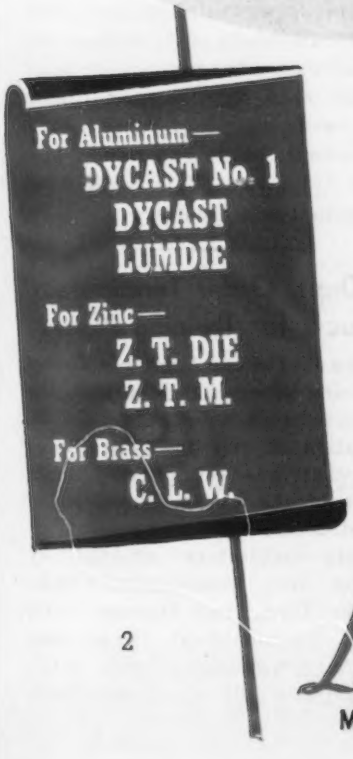
by a medical transfer department, maintained specifically to handle handicapped individuals, to locate jobs they can do, and to keep informed of their problems and progress.

I. D. Jenkins of General Motor's Harrison Radiator Division at Lockport, N. Y., explained that GM had surveyed every operation in its plant to determine the physical requirements to perform each job satisfactorily. He pointed out that a "person who can perform a job in a thoroughly normal and satisfactory manner is not a handicapped person on *that job*, even though he might otherwise be considered severely handicapped."

In the initial approach to its survey, General Motors devised a check sheet. A man capable of exercising discretion and selection was assigned to examine everyone of the jobs with the foreman, and, in many instances, with the operator on the job. This, it is said, was to determine briefly the degree of eyesight, hearing, finger, hand, and arm dexterity required;

LATROBE
DIE CASTING STEELS

We will be glad to give you, without obligation, technical advice on your die-casting steel problems. Write.



Latrobe Metallurgists and engineers are abreast of the most recent developments in the increasingly important Die Casting Industry, and their painstaking research is constantly directed toward the production of steels that will improve die performance.

Co-operation between customer and supplier is essential for real success in providing the correct steels to meet the requirements in this field... to this can be attributed the results obtained with Latrobe's Die Casting Steels for Aluminum, Magnesium, Zinc and Brass.

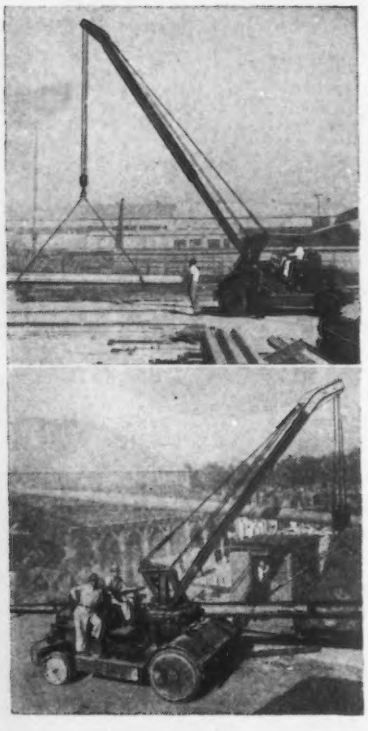
goes and moves it

quickly, at low cost



● No expensive delays—Roustabout Crane picks up and moves your motor, machine, casting, crate, I-beam or whatever it is, big or small, easily, instantly. It keeps things to 5 tons moving around your factory, railroad, dock or airport. It's *where* you want it *when* you want it. On wheels or crawler tracks, it's easy to run, all tractor power, ball-bearing boom turntable, gears in oil, full boom swing—built for years of punishing work. Roustabout Crane is a highly profitable investment in post-war efficiency. Write now for the whole story.

whether the operation could be performed sitting all the time, standing all the time, or whether this was optional; whether one or both feet or legs were needed; whether the height and weight of the worker was important; the amount of lifting involved and its frequency, the posture required by the job; work station conditions; work station surrounding, with reference to noise; proximity to other employees, moving machinery, etc.; operational hazards; and required safety protection for the individual's eyes, hands, feet and body.

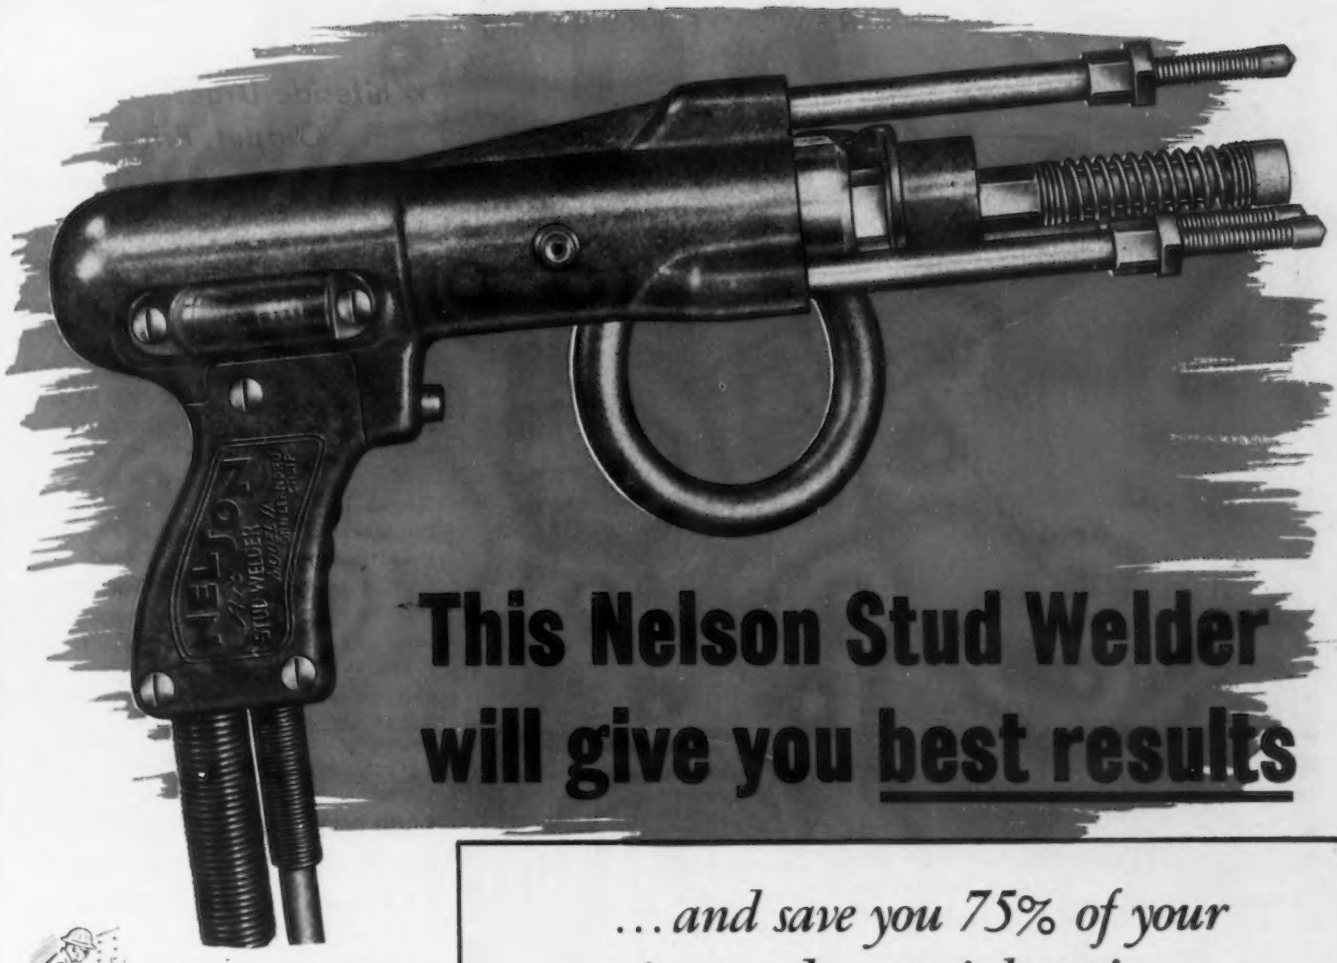
"Following the completion of this survey, tabulating cards were being punched with a view to the selection of a suitable job in the shortest possible time. To illustrate: If we have a totally blind individual to place, how many jobs do we have where vision is of no importance so far as the job itself is concerned? The tabulation run will give this information in a matter of moments. Then careful selection must be made to determine whether or not the location of the job affords any problem for the individual without vision and, if so, whether there is any practical way of meeting this difficulty," Mr. Jenkins said.

A. A. Hendrix of General Motor's, Eastern Aircraft Division, said that their job placement plan for veterans is headed by an industrial psychiatrist, assisted by the safety director, educational director, and employment manager, all of whom work with the individual supervisors on the plan. The plan starts, he said, with a survey of all ex-service men in the plant to collect such data as age, reason for discharge, length of service, military citations, battle experience, personality type, etc. This is followed by individual case studies.

War Dept. Order Terminates Contracts for Training Planes

• • • **The need of the Army Air Forces** for training planes has been met, the War Department announced Feb. 28. Termination of existing contracts of such aircraft has been ordered to insure use of the workers involved in the construction of combat craft.

Primary contractors affected by the order are: Consolidated-Vultee, Nashville, Tenn., and Downey, Cal., Aeronca, (Aeronautical Corporation of America) Middletown, Ohio; Fairchild Aviation Corp., Hagerstown, Md.



This Nelson Stud Welder will give you best results

SOME WAYS OTHERS ARE USING THE

NELSON MODEL "H"

Securing parts to steel castings of all types.

Installing and manufacturing portable steel scaffolds.

Insulating interiors of refrigerator and freight cars.

Prefabrication of houses and all types of buildings requiring insulation.

Securing electric cables, light fixtures and switch boxes.

Securing all types of wood or plastic decking.

Installations of many types in locomotive cabs.

... and save you 75% of your time and material, too!

The NEW Nelson Model "H" Stud Welder is completely automatic in operation—you get full fusion of stud to plate in less than ½ second. *A new worker can weld 500 to 1000 studs in a day.* Complete fusion of stud to steel results from automatic action of the gun, accurate controlled arc timing, and the use of flux-filled studs. A porcelain ferrule completely shields the arc.

Light in weight—easy to handle, the Nelson Model "H" has answered the stud welding and insulation problems of over 200 industries in the United States and Canada. Railroads, truck manufacturers, machine tool makers, etc., have found good results. Fit the Nelson Stud Welder into *your* operation today, or your post-war plans for tomorrow. *Write now for complete details and catalog!*

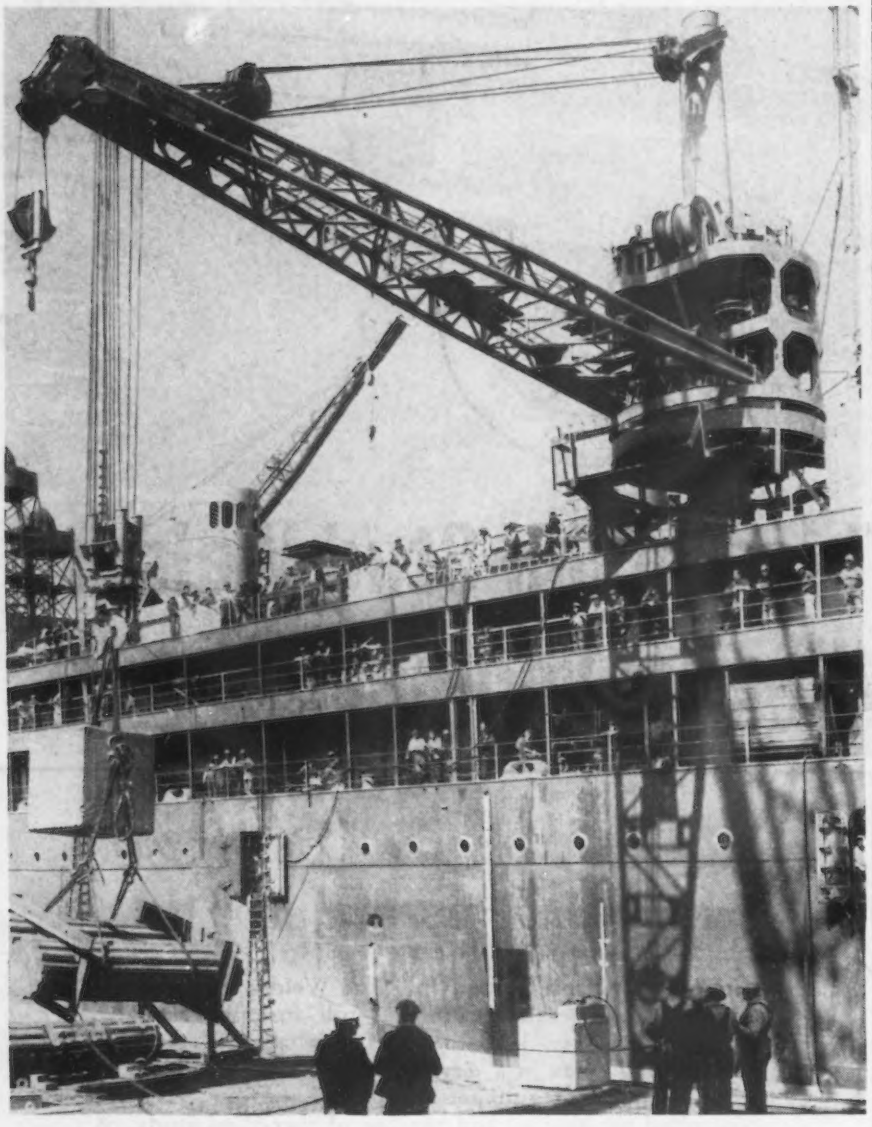
Flux-filled studs are available in many diameters and designs. Also insulation pins for applying Fiberglas and sprayed-on asbestos. Sizes and prices on request.

For complete details, samples, and catalog, write to:

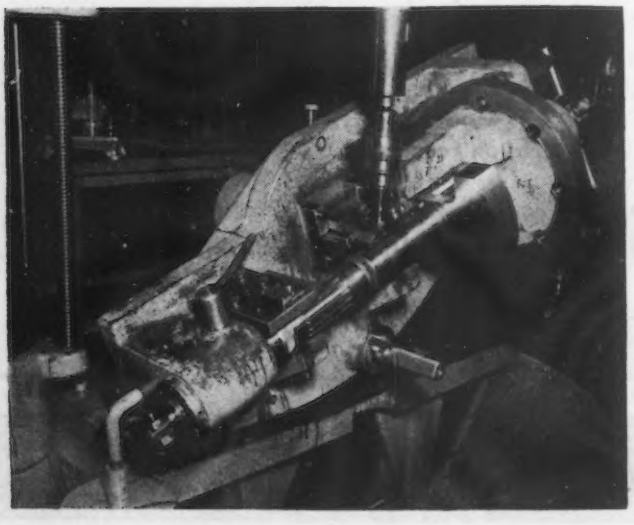
NELSON SPECIALTY WELDING EQUIPMENT CORP.
Dept. 1, 440 Peralta Ave., San Leandro, Calif.

Eastern Representative: Camden Stud Welding Corp., Camden, N.J.

NELSON STUD WELDERS & STUDS



CRANE INSTALLATION: A Western Gear boat and airplane crane undergoes testing during installation on a submarine tender at Oakland, Cal. The crane incorporates features not used on previous boats of this nature. The equipment consists of a main winch which tops and lowers the boom, a boat winch, an airplane winch and rotating machinery. It has an operating load of 45,000 lb.



SPEEDS DRILLING: The Lycoming Div. of Aviation Corp. has developed this special jig for the drilling and reaming of all small holes in crankshafts for its R-680 engine in one operation. Five separate jigs formerly were required for this operation. Set-up time is cut 80 per cent and loss of material caused by handling damages has decreased proportionately.

Whiteside Urges Output, Price Curbs

• • • **Government** control of civilian goods production for a three-year postwar period was advocated recently by Arthur D. Whiteside, former vice-chairman of WPB in charge of civilian requirements, before the American Retail Federation in New York. Mr. Whiteside believes that output of goods should be held at 1939 levels to prevent overladen markets and heavy unemployment later on.

Mr. Whiteside's views were challenged by several other speakers at the meeting. Fred Lazarus, Jr. urged that the quota system be eliminated. B. E. Puckett held that consumer and worker needs should take precedence over any vested rights to production.

Mr. Whiteside asserted some workable price control should be worked out in the postwar era.

$809,000,000 Spent in 1943 For Foreign War Commodities

• • • **Contract deliveries** of strategic commodities bought in foreign countries with government funds under the FEA public purchase program totaled $809,000,000 in the year ending Dec. 31, 1943.

Below is the approximate dollar value of deliveries by major commodity groups under the FEA public purchase program contracts. The figures do not include preclusive purchases of materials in neutral countries made under FEA direction in order to keep the enemy from obtaining supplies he needs.

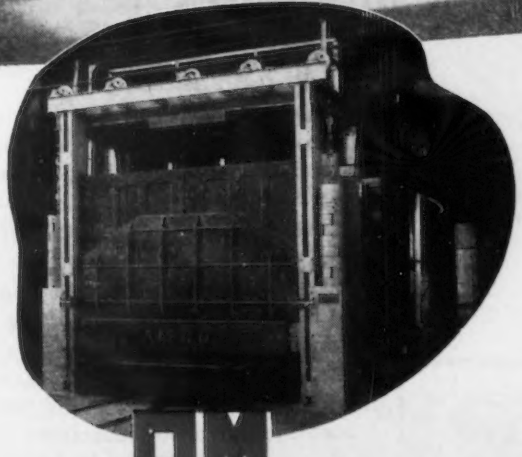
YEAR 1943 (000 Omitted)	Jan.-June	July-Dec.	Year
Metals and minerals	$232,000	$264,000	$496,000
Foodstuffs	60,000	73,000	133,000
Textiles	51,000	65,000	116,000
Misc. commodities	35,000	29,000	64,000
Total	$378,000	$431,000	$809,000

Harrison Weymouth Dies

• • • **Harrison Weymouth** formerly with the Baltimore sales office of Bethlehem Steel Co., died Feb. 5. He had also been connected with the Pennsylvania Steel Co. which was taken over by Bethlehem and is now a part of its Sparrows Point, Md. plant. His experience in the industry covers more than a quarter of a century. He was retired at the time of his death.

AMCO

CAR TYPE FURNACES

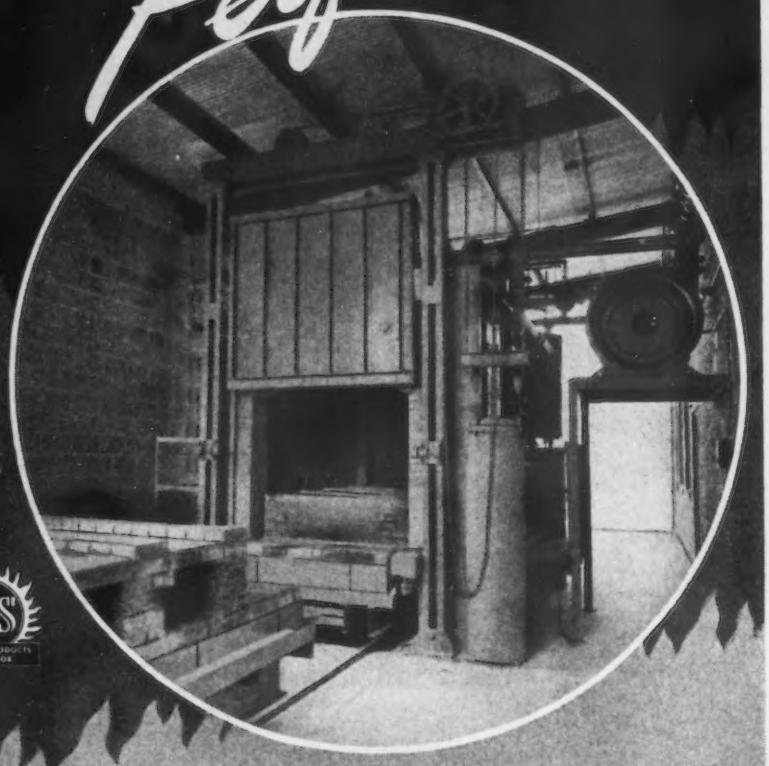


AMCO Car-Type Furnaces are built not only for the emergency, but for many years of commercial production thereafter . . . *It pays to buy the best!*

The AMSLER-MORTON Company

FULTON BUILDING · PITTSBURGH, PA.

AN "OPEN DOOR" TO HEAT-TREATING *Perfection*



The metallurgist and superintendent in the stainless steel foundry where this R-S Car Hearth Furnace was recently installed agree that "it is a fine piece of equipment and doing an exceptional job."

The uniformity and physical properties obtained are far superior to results previously secured. Gas-fired and equipped with two-zone temperature control, this furnace reflects the skill and painstaking care of R-S Engineers in adapting R-S equipment to a particular heat-treating problem.

Regardless of the scope or type of your heat-treating requirements, the door is always open for consultation with R-S Engineers. Heat-treating perfection is the watchword.

FEA Reports on Russian Aid

Washington

• • • **Shipments of munitions** and other war supplies under Lend-Lease from the United States to the Soviet Union in 1943 were almost double 1942 shipments, according to the Foreign Economic Administrator, Leo T. Crowley. A total of 8,400,000 tons of supplies valued at $4,243,804,000 was exported to Russia from the beginning of the program in October, 1941, to Jan. 1, 1944. Shipments in 1943 totaled 5,400,000 tons, compared with 2,800,000 tons in 1942. December, 1943, shipments were the largest on record for any single month.

While more ships were sent to Russia in 1943 than in 1942, a greater percentage also arrived, 99 per cent of sailing reaching port in safety during the past year. In 1942, only 88 per cent reached Russia, due to enemy submarine, surface raider, and bomber interference.

Up to Jan. 1, 1944, more than 7800 planes had been sent to the Soviet Union. Over 3000 of these were ferried all the way by air. More than 5000 planes were sent in 1943, twice as many as in 1942. Virtually all planes sent have been combat types. In 1943 they were principally Bell Airacobra P-39 fighters, Douglas A-20 attack bombers and North American Mitchell B-25's.

To Jan. 1, 1944, over 4,700 tanks and tank destroyers, 170,000 trucks, 33,000 jeeps, and nearly 25,000 other military motor vehicles were shipped. Army boots have been shipped, together with large quantities of food needed to maintain the Soviet Army rations. Food shipments up to Jan. 1, 1944, totaled 2,250,000 tons.

In addition to food, we have sent 9000 tons of seeds to aid in new agricultural regions and in devastated areas reconquered from the Germans.

Other shipments to the Soviet Union up to Jan. 1, 1944, have included: 177,000 tons of explosives for manufacture into bombs and shells in Soviet factories; 1,350,000 tons of steel; 384,000 tons of aluminum, copper and other metals; $400,000,000 of industrial equipment, machinery, and machine tools; and 740,000 tons of aviation gasoline and other refined fuels and lubricating oils.

In order to reduce the Soviet's need for refined fuels from the United States, 145,000 tons of refinery equipment have been sent for installation in the U.S.S.R. American engineers in the U.S.S.R. are now assisting in

MILLING THE *Dome* IN ALUMINUM CYLINDER HEADS FOR AVIATION ENGINES ON THE HALL PLANETARY

This Planamilling job consists in milling the thread and shrink band clearance for the subsequent operation of milling the thread and shrink band diameter. The operation takes about TWO MINUTES on the Planetary. Close "aircraft" accuracy is easily maintained.

☆

Send us your prints for suggestions on speeding war production with Planetary milling and threading.

REJECTS REDUCED

-Since Spencer Vacuum was installed!

That's the report from a large Buffalo foundry. If rejects in your plant are due to dirt, dust, chips, or any extraneous material, you should have a similar experience with Spencer Vacuum.

It is ideal for precision operations such as watches and communication equipment. It will reclaim materials, or convey slag, lead shot or glass sand by the ton. It will take liquids out of tanks and sumps, or clean the most complicated machinery.

The 7½ horsepower portable shown at the left is ideal for large areas and heavy work, or a Spencer Stationary system may be piped to all parts of the plant. Ask for the bulletins.

Spencer also Recovers Sand and Removes Chips Scales and Abrasives

SPENCER HARTFORD VACUUM CLEANING

7

the construction of these refineries which will, when completed, produce large additional quantities of aviation gasoline and other refined products from Russia's own oil resources.

Similarly the United States shipped to the Soviet Union in 1943 used and new machinery for a complete tire factory that can produce at least 1,000,000 military truck tires annually from the Soviet's own synthetic and natural rubber supplies.

Chain Belt Employee Gets War Department Citation

• • • **John P. Hess**, foreman in the Ordnance Division of Chain Belt Co., and employee of the company for 15 years, has been awarded the first War Department citation in the Milwaukee Regional Office of the Chicago Ordnance District and the 143rd citation in the entire nation.

Mr. Hess gained this recognition by designing a new tool for ordnance production which accelerated production, made unnecessary the purchase of additional machinery, and saved 36,000 man-hours. This new tool finishes in one operation the work formerly done in three cuts.

New Books

• • • **"Mechanical Properties of Metals and Alloys,"** issued by the National Bureau of Standards, has been brought up to date. The new edition, 482 pages, is for sale by the Superintendent of Documents, U. S. Government Printing Office, for $1.50. The book includes new data on the numerous alloys introduced since 1924.

"Time Study Engineering," by William H. Schutt, president, Detroit Time Study School, deals with phases of time study applied to specific machines for the purpose of determining cost, pay and production efficiency.

Simplified explanations of machine speeds and feeds are given, with an analysis of production line tasks. (McGraw-Hill Book Co., $5.).

"Lubricants and Cutting Oils for Machine Tools," by William G. Forbes is a practical reference book for lubrication and cutting oil problems. Standard laboratory tests on new and used oil are outlined in simple form and the action of cutting tools is illustrated to help solve cutting problems as they arise in practice. (John Wiley & Sons Inc., $1.50).

works this way . . .

on a Cross Special Machine that anyone can operate

CROSS Engineers designed and built this machine for a specific purpose—to face and center or drill both ends of axle shaft forgings, and provide continuous, automatic production of from 100 to 130 pieces per hour. At the push of a button, the forgings are hopper-fed and automatically clamped, machined, unclamped, and ejected in a continuous production process.

Thus milling and centering or drilling are combined into one fully automatic operation by means of a Cross *Special Machine* that *anyone can operate.*

By modifying the design of this machine, similar forgings of different dimensions can be machined in the same way.

The principle behind all Cross *Special Machines* is the same—removal of metal at lower cost on automatic equipment that anyone can operate. It is a principle that can be applied to any type of machining operation, a principle that is being used successfully in hundreds of plants all over the world.

Cross Production Engineering is a complete service. Cross Engineers are available now to survey your present machining methods and, if special machinery can lower your costs or help solve your labor problem, they will design, build and install the machines for you, and show your workmen how to operate them.

The new Cross Catalog contains 38 case histories of successful Cross *Special Machines.* A copy is yours for the asking. Just write on your company letterhead to The Cross Company, Detroit 7, Michigan. Department 12

for automatically performing any one or a combination of metal cutting operations

TURNING · MILLING · DRILLING · BORING · REAMING · TAPPING · GRINDING

THESE EUCLID CRANES

Almost without exception EUCLID CRANES outlast normal life expectancies because quality is built into even the smallest parts to assure many years of efficient, economical service.

High grade, wide face coarse pitch gearing is used throughout. Shafts are short and strong to withstand torsional stresses. Anti-friction bearings assure longer life and lower power consumption. Every part has a liberal factor of safety.

EUCLID CRANES of standardized design, with all parts jig-machined to assure interchangeability, are built in capacities from 3 to 25 tons with spans from 20 to 100 feet. Larger and heavier cranes of greater capacity are built on special order.

Every detail of construction reflects the combination of traditional EUCLID ruggedness and simplicity with perfected and proven principles of electric crane design.

★ WE CAN DELIVER A LIMITED NUMBER OF 5 to 10 TON CRANES in 60 to 90 Days

Metallurgical Techniques In Seized Enemy Patents

• • • **This is the seventeenth** list of seized enemy patents, available on license from the Alien Property Custodian. These patents are grouped in classes. Sub-class numbers are shown first in parentheses, followed by the patent number, description of the patent, the inventor's name and nationally, and the date of issuance.

This series began in the Nov. 4 issue of THE IRON AGE, page 95, at which time procedures for obtaining the patents for use were described with information concerning their usage and possibilities. Seized patent applications were shown in THE IRON AGE on July 8.

Class 75—Metallurgy (Continued)

(50) 1,955,481. Process for the production of pig iron having a fine graphitic texture. A Wirtz, Germany. 4-17-34.

(51) 1,650,157. Process for the elimination of phosphorus from pig iron. R. Schenck, Germany. 11-22-27.

(51) 1,787,806. Process for separating zinc sulphate from sodium sulphate. H. Weidmann, Germany. 1-6-31.

(51) 1,936,282. Method of measuring the elongation of hollow cables. G. Zapf, Germany. 11-21-33.

(51) 2,258,850. Process for desulphurizing iron or iron alloys. F. Eulenstein and A. Krus, Germany. 10-14-41.

(53) 1,970,067. Process for the production of age-resisting iron and steel. C. Wallman, Firtz Halbrock and E. Kumpmann, Germany. 8-14-34.

(54) 1,730,960. Process of purifying pig iron. F. Wust, Germany. 10-8-29.

(54) 1,782,923. Process of purifying pig iron by means of a dephosphorizing and desulphurizing slag to which carbon as been added. K. Hoffmann, Germany. 11-25-30.

(55) 1,651,492. Process of desulphurizing molten metal and briquettes used therefor. R. Walter, Germany. 12-6-27.

(57) 2,173,205. Process for the deoxidation of steel baths. O. Johannsen, Germany. 9-19-39.

(57) 2,237,485. Process for the deoxidation and degasification of steel. P. Hardt, Germany. 4-8-41.

(58) 1,818,556. Method for the purification of iron and steel. M. Jaeger, E. Pokorny and G. Gossrau, Germany. 8-11-31.

(58) 2,120,894. Method of producing free cutting steel. J. Haag, Germany. 6-14-38.

(59) 1,821,407. Process of decarburizing iron or steel or their alloys. W. Schottky, Germany. 9-1-31.

(60) 1,846,234. Refining process for producing pure iron. H. van Royen, Germany. 2-23-32.

(60) 2,093,666. Process for treating iron and iron alloys. A. Vogt, Germany. 9-21-37.

(62) 1,759,661. Production of pure metals in a finely divided state by the thermal decomposition of metal carbonyls, other than iron carbonyl, or mixtures of same either with each other or with iron carbonyl. C. Muller and W. Schubardt, Germany. 5-20-30.

(63) 1,739,992. Process of working up mixed shavings of white metal and red metal. A. Schwarz, Germany. 12-17-29.

(63) 1,819,607. Method of treating waste alloys for the purpose of removing therefrom certain constituents whose presence renders the alloys unsuitable for certain uses. P. Kemp, Austria. 8-18-31.

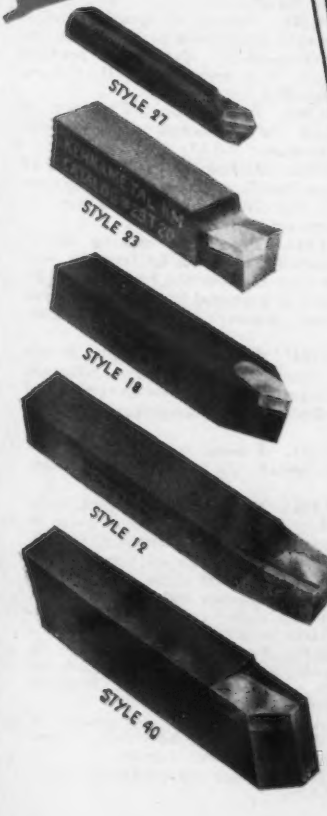
(63) 1,864,161. Separating and recovering non-ferrous metals from metallic initial materials. W. Wittner, Germany. 6-21-32.

(63) 2,207,461. Separation of the constituents or alloys or mixtures of metals and/or elements similar to metals. P. Kemp, Germany. 7-9-40.

(63) 2,254,805. Process for the separation of metals. E. Junker and W. Leitgebel, Germany. 9-2-41.

(65) 1,827,174. Method of melting oxidizable

THE RIGHT STEEL-CUTTING TOOL *for every Job*



To get maximum steel-cutting production—consult KENNAMETAL field engineers about the proper application of KENNAMETAL, the wear-defying tool material whose chief ingredient is a unique, super-hard intermetallic compound (tungsten-titanium carbide). KENNAMETAL engineers will help you . . . (1) select the right grade . . . (2) choose the correct tool style . . . (3) determine the most efficient machine set-up . . . (4) install a money-saving tool maintenance program.

Yes, KENNAMETAL engineering service assures the *right* KENNAMETAL tool on every job . . . and performance studies show that the *right* KENNAMETAL tool, used properly, often can remove stock from the toughest steel up to 3½ times more efficiently than other carbides! There's a KENNAMETAL field engineer in your locality. Ask him for advice—and always keep a copy of our Tool Manual on hand. Write for one today.

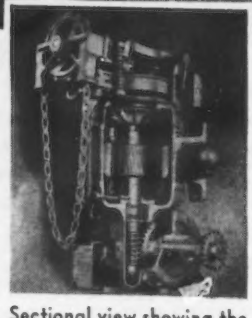
Install KINNEAR ROLLING DOORS and gain these advantages



Sectional view showing the rugged construction of the Kinnear Motor Operator.

When you install Kinnear Rolling Doors you gain more than smooth, easy operation. Kinnear Rolling Doors coil overhead, out of the way, offering valuable savings in floor, wall and ceiling space. The sturdy, interlocking steel-slat construction discourages theft and intrusion; repels fire and the elements. Kinnear durability has been proved — doors in continual use for 20, 30, and even 40 years are still giving the same efficient service. Motor operation enables you to raise doors quickly by merely touching a button, thus saving time and labor. Push-button control cuts operating and air-conditioning cost by reducing the tendency to leave doors open. For efficient time- and labor-saving doorways, write for full details on Kinnear Rolling Doors. The Kinnear Manufacturing Company, 1760-80 Fields Avenue, Columbus 16, Ohio.

Operators "CATCH-ON" Quicker

P&H ARC WELDERS

SIMPLER TO OPERATE

These outstanding advantages mean simpler operation to speed production, reduce training time and assure better welding results to aid the war effort.

SINGLE HEAT CONTROL—An infinite number of current settings with but one simple adjustment. An operator can't be confused. Machine provides automatic arc response on all classes of work — with all classes of electrodes.

"VISI-MATIC" CALIBRATION — Enables operators to select exactly the right current across the arc for each of the three classes of electrodes—high, medium, or low voltage.

WSR (Welding Service Range) RATINGS — Shows the exact limits of *usable* welding current the machine will deliver, from minimum to maximum capacities. There is no guesswork. You *know* what you can do.

CUT YOUR WELDING COSTS

With these vital advantages, operators spend more time actually welding, reducing time and costs.

Moreover, square frame design permits stacking of machines and instant parallel hook-up. You can use two separate services or the combined amperage of two, or even three, machines in one service. It gives you greater welding flexibility, greater convenience and lower costs.

See your nearest P&H representative, or write us for literature.

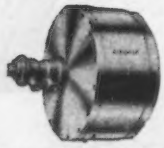
PARTS COME AT LEAST 25% FASTER

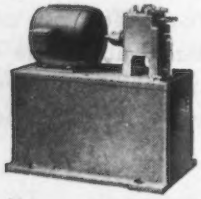
when

"AIRGRIP" chucks and cylinders are used!



Wear is automatically taken up in the "Airgrip" double acting, ball bearing, high speed revolving air cylinder.

"Airgrip" chucks are self-locking when gripping either externally or internally. Cam and lever action doubles the gripping power obtained through leverage alone.



A ½-hp. motor drives this 3,000-lb. Hi-Po hydraulic pump. Pressure is built up fast, and power is delivered with minimum pulsation. You will want to know more about this new Hi-Po pump. Write for bulletin.

Finished parts will pile up faster—at least 25% faster—and at lower cost, as soon as "Airgrip" chucks and cylinders are installed on your machines.

Precision built to highest specifications, these devices will give long, trouble-free service. They are designed and constructed to permit heavier cuts and coarser feeds up to the limit of a machine's power and the endurance of cutting tools.

For faster and lower cost production, put your pneumatic and hydraulic problems up to Anker-Holth engineers. They are at your service—and without obligation to you.

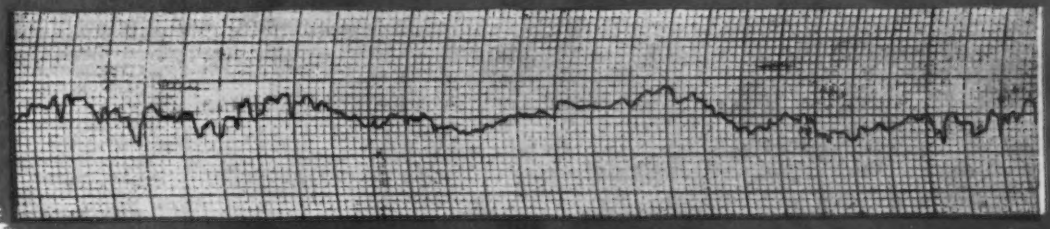
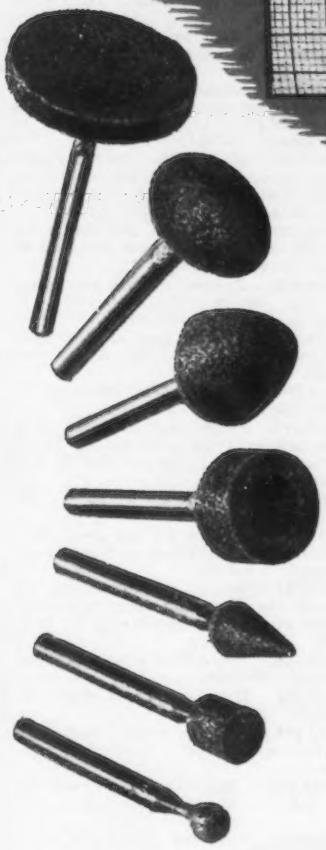
Proof of a Better Finish



Each small square represents 1.0 micro inches. Micro inch r.m.s. = 0.9 — 1.8.



Surface Analyzer Tapes Show You Get A Better Finish With Chicago Wheels

These results were obtained at a rate of 10 pieces per hour in an aircraft parts plant. Material, X-13-15, Rockwell 60 to 57, grinds out .006 to .007 stock. Chicago Wheel used, ½ x ½ x ⅛", Grain 180, Grade L Arcite. Spindle Speed 40,000 r.p.m. Lapping and super finishing eliminated on this job.

Can you match that finish? Sounds phenomenal, but you can do the same thing with Chicago Wheels.

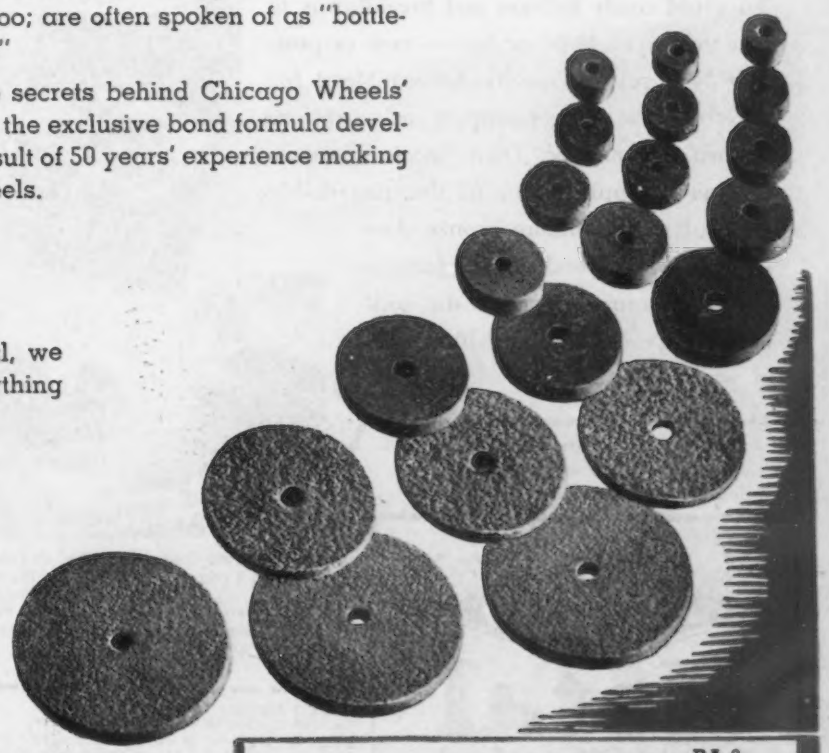
Squint your eye along the surface, test it by "feel" or be scientific and use a surface analyzer to measure your finish in micro inches — you'll find that Chicago Wheels give you better finishes, hold closer tolerances and have longer life. They're mighty fast, too; are often spoken of as "bottle-neck busters."

One of the secrets behind Chicago Wheels' superiority is the exclusive bond formula developed, as a result of 50 years' experience making grinding wheels.

Now Featuring Wheels Up to 3" in Diameter

For the duration, with full WPB approval, we are specializing on the small sizes — anything up to 3" in diameter.

Write for Catalog and we will include Engineering Survey Forms helpful in getting the right solution to your own grinding problems.



Half a Century of Specialization has Established our Reputation as the Small Wheel People of the Industry.

...war-tested ideas for more successful post-war products

... with parts of wear-resisting Ampco Metal

To avoid costly failures and breakdowns in equipment you build or buy — now or post-war — it pays to specify Ampco Metal for parts subject to wear, impact, or corrosion. Ampco Engineering Data Sheets illustrate dozens of applications of this remarkable alloy of the aluminum bronze class —which lasts several times as long as ordinary bronze. Here is the condensed experience of over 2000 users in war and peace.

A-2

Ampco's nation-wide organization of field engineers is available to help you solve your problems of metal failure.

Valuable Data Free for Builders and Users of: Machine Tools . . . Aircraft . . . Pumps and Valves . . . Engines . . . Ordnance . . . Ships . . . Heavy Machinery . . . etc, etc.

Write today on your business letterhead, or tear out and mail coupon.

Saved! 27,600 POUNDS OF GREASE!

SUN LUBRICANTS

Cut Grease Consumption 92% . . . Save $2874.00 a year

When a change in lubrication cuts grease consumption 92% . . . it's news that should interest management in any industry.

30,000 pounds of grease a year to lubricate the open gears of one paper-making machine was the problem of an eastern producer. Dissatisfied with this performance, the plant manager called in a Sun Engineer. In short order he discovered that the grease being used did not have the adhesive qualities to prevent it from dripping.

The Sun Engineer's recommendation was a change to a Sun Adhesive Lubricant . . . and it brought spectacular results. Frequency of lubrication was reduced from daily application to application once every two weeks — a saving of 27,600 pounds of grease a year. This 27,600 pounds meant $1714.00 less spent for lubricant, $1160.00 less for labor, or a total saving of $2874.00. On the basis of this performance, use of the same Sun Lubricant has been extended to eight machines in the mill, with a corresponding increase in savings.

This is typical of every day service through which Sun Engineers and Sun Lubricants help American industry speed production and increase operating efficiency. To start the service working for you, just write

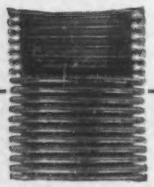
REX-FLEX Stainless Steel Flexible Tubing Is *Non-Corrosive*

REX-FLEX Stainless Steel Flexible Tubing was designed by Chicago Metal Hose Corporation to meet exacting military requirements. Its proved ability to successfully handle many types of corrosive gases and liquids and to withstand extreme heat, makes REX-FLEX equally desirable for the solution of *your* corrosion problems.

REX-FLEX is available in five wall forms, braided or unbraided. Fittings are resistance seam-welded to form uni-metal assemblies.

Why not take advantage of the experience of Chicago Metal Hose Corporation's engineers in adapting this versatile product to the wide range of problems requiring the stamina of stainless steel? They will be glad to give you their recommendations, without obligation. Write for complete information today.



REX-FLEX
STAINLESS STEEL
FLEXIBLE TUBING

Note These Features

- Corrosion resistance
- Extreme flexibility
- Pressure tightness
- Lighter weight
- Withstands extreme temperatures
- High fatigue resistance
- Seam-welded fittings

METAL STAMPINGS

★

MODERN DESIGN AT LOW COST

★

HOUSEHOLD APPLIANCES

New refrigerators, cabinets, bathtubs, stoves, and a wide range of other household necessities will be a joy to the post-war housewife.

Pressed Metal Parts and stampings will make possible unparalleled efficiency, smart beauty, long life,—all those qualities that lower sales resistance in a competitive world.

No other method provides *all* characteristics required,—resistance to elements, ability to take hard knocks in every day use, relative low cost, tensile strength, beauty and so forth. Parish Pressed Steel has completely rounded facilities; engineering cooperation in the drawing board stage, all sizes of presses for most efficient production, welding facilities, painting and finishing departments, and full assembly facilities.

It is not too early to plan your new designs. We are ready to work with you in the preliminary stages.

And as our contribution to post-war progress, we are now equipped to stamp, fabricate, and heat treat aluminum, in addition to steel.

Trade Notes

Allis-Chalmers Mfg. Co., Milwaukee, has established a new Texrope department to handle the Texrope line of multiple V-belts and sheaves. The new department is part of a reorganization move in which Allis-Chalmers set up a separate basic industries department.

•

Springfield Heat Treating Corp., Springfield, Mass., has succeeded the former Gorman Heat Treating Corp. located in the old East Springfield Rolls-Royce plant. Additional facilities will be installed, primarily for conservation of alloy steels used for tools and ordnance material in western Massachusetts plants.

•

All-Tools Co., Inc., Milwaukee, Brumder Building, has been organized by Lyman P. McIntosh, Charles Ackermann and Paul H. Paulsen.

•

Milwaukee Screw Parts Co. has been organized at 161 W. Wisconsin Ave., Milwaukee.

•

J. K. Smit & Sons announce that they have no connection whatsoever with Leonard J. A. Smit and Anton Smit & Co. who were recently named in U. S. proceedings in connection with certain diamond transactions.

•

Taylorcraft Aviation Corp., Alliance, Ohio, is consolidating its four factories into one by adding 74,000 sq. ft. of floor space to its main plant.

WPB Makes Changes in General Scheduling Order

• • • **WPB has issued** Direction 1 to the General Scheduling Order. The effect is to provide that wherever the designation of an item under Order M-293 is changed by an amendment to a table, or an item is removed from a table, or wherever an item under a scheduling order becomes an M-293 product and is removed from such other scheduling order of WPB, manufacturers of the item in question must continue to observe any frozen schedules or specific directions which they received under the earlier procedure, unless the schedule or direction is amended under Priorities Regulation 18.

Where the placing of a purchase order was approved for a Class Y item, or for a product covered by similar procedure under any other WPB order which was or has become an M-293 product, the approval remains effective and the person with whom the purchase order is placed must accept and schedule the same accordingly, even if he receives it after the item is reclassified.

WPB has also issued Direction 2 to M-293 pointing out that despite the amendment of the scheduling order, the tables 3-15, which apply reporting forms to various types of commodities, remain in effect until those tables are themselves changed or amended. It is added, however, that the classification of any product on any table as a Z product must be disregarded.

Briefly Told—

• While slight improvement in plastics production is expected by the middle of the year, the supply situation will remain critical throughout 1944, leaving little for civilian allocations, according to Clinton Rector, chief, plastics section, WPB. Contrary to expectations growing out of increased allocations of plastics during February for civilian items growing military requirements may necessitate cuts in such allocations.

•

• Utilizing a base of plastic resin, a new packaging material was announced by the Goodyear Tire & Rubber Co. The material has been named "V-Film." Although not a substitute, "V-Film" is an alternative in some applications for Goodyear's prewar Pliofilm, made with a rubber hydrochloride base. Pliofilm requires natural rubber so its use is limited to moisture-proof protection of airplane engines. "V-Film" is made with a derivative of polyvinyl chloride. A major advantage of "V-Film" is that it can be produced on equipment installed originally for the manufacture of Pliofilm.

•

• The Welding Equipment & Supply Co., Detroit, has had prepared a sound slide film program involving two separate films with their accompanying recordings. They cover arc welding of tools and dies, a subject that has not been delved into to any great extent by manufacturers of welding rods because of its specialized applications.

•

• The council of The Institute of Metals (British) has elected four Honorary Members of the Institute, one each from the four principal Allied Nations: China, Her Excellency Madame Chiang Kai-Shek; Great Britain, Sir Lawrence Bragg, F.R.S.; United States of America, Dr. Irving Langmuir; and Union of Soviet Socialist Republics, Professor P. Kapitza, F.R.S.

•

• Plans have been completed whereby the American Society for Metals will provide an annual fund of $1000 for support of fundamental researches in the field of corrosion. The American Coordinating Committee on Corrosion has been designated to receive and approve applications for grants from this fund. This committee will select such research projects as appear worthy of support, approve the qualifications of applicants for grants-in-aid from the fund, and certify to the Society names of successful applicants. The grants-in-aid will vary from $250 to $1000.

•

• Commercial airliners that will burn furnace oil costing only six cents a gallon instead of high octane gasoline that costs about four times that amount, were foreseen by Gordon Lefebvre, president of The Cooper-Bessemer Corp. "It is logical to assume that within the next five years, all commercial aircraft engines will be diesels," said Lefebvre. In addi-

CONTROLLED QUALITY STEEL FOR WAR

QUARRIES

Like the first winter snow, everything in and around quarries producing limestone for the steel industry is always covered with fine, grey-white lime powder. This harmless stone dust coats the work clothes of the quarrymen, powders their faces, dusts their eyebrows and mustaches, giving them a grizzled, wintry look. All the area around the stone-crushing plant is powdered white and has the appearance of always being in a slight haze.

No quiet retreat is a quarry. Drilling rigs chatter incessantly as they bore shot holes for dynamite crews. The big drag line drops its great steel bucket into the quarry with a thunderous crash. Squat, puffing, hard-working, narrow-gauge locomotives, with much bustle and authority, shove funny little 10-ton dump cars to the crushing plant.

The rocks crash and bound against the sides of the crusher's funnel-shaped maw as the cars are dumped. The huge, powerful steel crusher thumps, thumps, thumps and roars and gnashes, as it disintegrates great slabs of rock as easily as a small boy disposes of a cookie. And then the screens make a racket like hail on a tin roof as they sort out the sizes of stone for various uses.

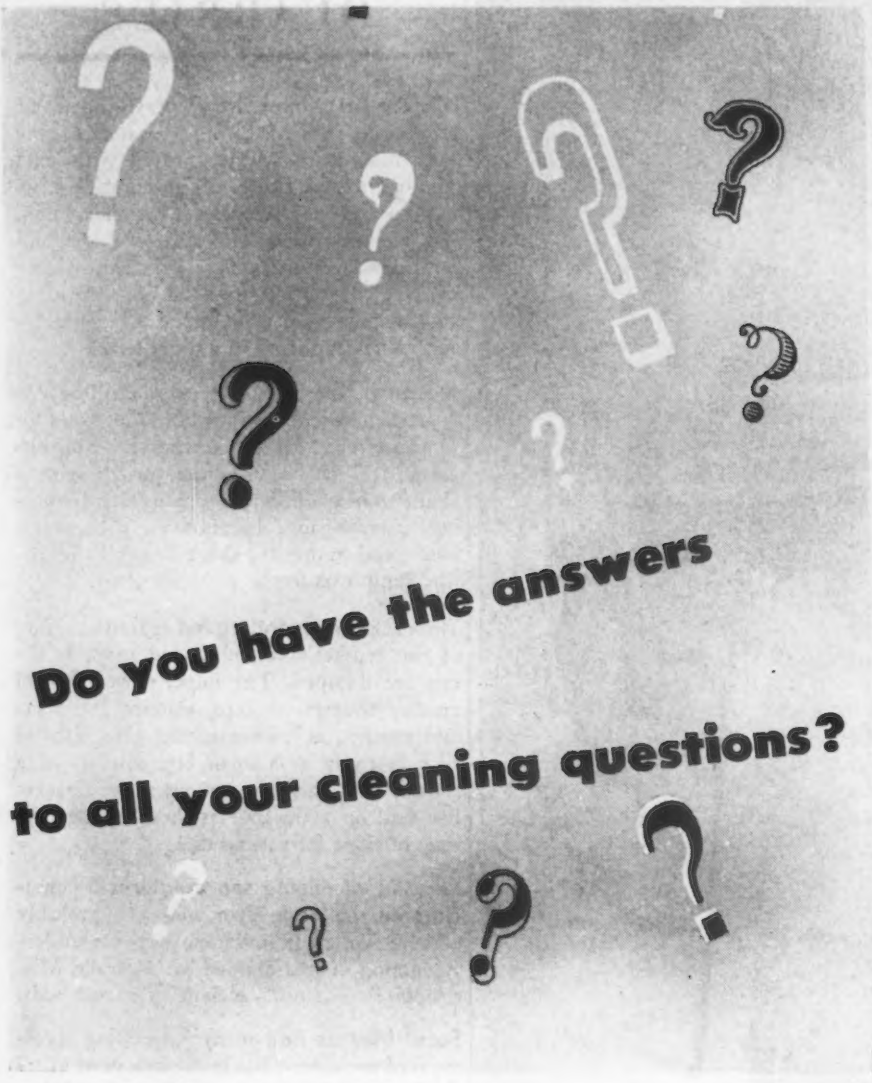
Remains of minute sea creatures accumulated on the ocean floor eons ago, probably account for great limestone deposits underlying most of area drained by Ohio and Mississippi rivers, more ancient than coal beds.

Fossil hunters find many interesting specimens of prehistoric life in the limestone quarries as the light grey rock is blasted and dug out. A worm-like fossil is one frequently discovered in many rock formations.

Metallurgical limestone (calcium carbonate) must have exactly right chemical composition to be applied in manufacture of iron and steel, where it acts as a flux, or scavenger, collecting and fusing together under intense heat the impurities in the iron and steel, and then being run off as slag.

Furnace slag is not wasted but instead finds its way into many uses. Treated in various ways, it becomes heavy, lumpy railroad ballast, fine white granulated road building material, insulating material, roof covering, concrete aggregate, Portland cement, brick, sand for mortar and even fertilizers.

"You hike, you hike, you hike," that's what you do in the Infantry, a new song says. And then you need foot powder for those aching dogs after marching long miles under heavy pack. Foot powder for our soldiers is supplied by the QM Department, put up in containers of tinplate made in the steel plants of the U.S.A.; some of it from the J&L tin mills. But the greatest portion of tinplate production—about 90%—goes for tin cans and closures for containers for foods, fruits and beverages for our fighting men.



HIT-OR-MISS answers won't do—success comes with the *right* answers! That's where Wyandotte can help you—with a *full* line of metal cleaning and degreasing compounds.

In the rush of war production, of aircraft and munitions manufacture . . . for cleaning motor parts, projectile bodies, metal prior to plating and painting . . . for cleaning prior to anodizing, removing anodic film prior to spot welding, stripping airplane finishes . . . Wyandotte works swift wizardry.

Remember—there's a Wyandotte *specialized* cleaner for every metal cleaning problem and for use in every type of equipment. If you wish help on any problems, call in the Wyandotte Representative. He's always on tap.

tion to fuel economies, the diesel aircraft will also have the inherent advantages of the non-explosive quality of its fuel, plus the absence of electrical interference, one of the most common hazards in air travel.

•

• Borg-Warner Corp., Chicago, has secured an additional $50,000,000 VT loan through 12 Chicago, New York, and Detroit banks to provide working capital during the interim between cancellation of war contracts and final settlement. The credit extends to Dec. 31, 1946, and is in addition to a $15,000,000 bank credit arranged in 1942, which runs until July 1, 1947. This former credit has not been used. Interest on the new loan is 2½ per cent on the portion utilized, and ⅜ per cent per year on the unused portion.

•

• Arrangements have been completed by Studebaker Corp. with 25 banks in various parts of the country for an $80,000,000 VT loan in order to supplement working capital and to replace government advances formerly granted on war production contracts. The loan also will assure necessary working capital during the period between termination of war contracts and financial settlement. The agreement which will expire Dec. 31, 1946, provides that the company may borrow the sum in units of $4,000,000 or multiples thereof. These loans will be made against notes maturing in not more than 90 days and bearing 2¾ per cent interest. The unused portion of the credit will carry ⅜ of 1 per cent annual interest.

•

• A new type bomb rack giving better control over loads carried by warplanes has been patented by Clem G. Trimbach, chief of the developments-armament department of the Curtiss-Wright research laboratory in Buffalo. The patent has been assigned to C-W. Recessed into the underside of the plane wing, the rack can be dumped with its bombs all set to "safe" when preparing for an emergency landing on a friendly field, according to Trimbach. The rack also can be jettisoned when empty. It is removable for reloading, and a plane can "bomb up" somewhat like loading a clip of cartridges into a rifle. The bombs are loaded on an endless chain conveyor which is moved by a motor under control of the pilot or bombardier. When over a target, they are released one by one as they come into line with a bomb chute. The operator can drop single bombs, sticks or strings as he chooses by regulating motor speed.

•

• The Westinghouse Electric & Mfg. Co. surpassed all previous production records during 1943. Net sales billed were 47 per cent ahead of 1942 and amounted to $714,305,303, after voluntary price reductions in line with the company's renegotiation agreement in 1942. No reserves for renegotiation were set up in 1943, as it is considered that the reductions already made are sufficient. Net income in 1943 was slightly more than 3 per cent of the net sales billed for the year, being $22,355,300 compared with $17,366,841 in 1942. Although during the past year some $320,000,000 in war orders were cancelled, a total of $958,967,057 in new orders was entered on the company's books in 1943. At the end of the year the

At each step in the manufacturing process—from acid open hearth to finished forging—Standard exercises the most rigid, painstaking control. The materials used in Standard products are carefully analyzed by especially trained metallurgists and chemists, using the most modern approved testing equipment. Their job is to safeguard the quality built into every forging delivered to a Standard customer.

The Standard Steel Works Division of The Baldwin Locomotive Works traces its origin to the Freedom Forge, which was established in 1795. From those early days through the present Standard has kept pace with modern developments in the manufacture of steel products.

Thus, today, in the 119-acre Standard plant, quality is kept at peak, unaffected by tremendous war-time demands. The Baldwin Locomotive Works, Standard Steel Works Division, Burnham, Penna.

PRECISION PARTS

25 YEARS... a long grind

THE smoke of battle from the last war had hardly cleared away when the present owners of Ace went into business as makers of precision parts. Those first few years after World War I were not easy. But doing highly accurate work, and doing it better and faster, carried Ace steadily along until today it is one of America's outstanding precision metal-working plants.

To our customers and suppliers with whom we have had the privilege of working during this quarter-century, we extend our hearty thanks. To future customers, we pledge the same careful attention to specifications that has made so many friends for Ace in the past.

Let us quote you on small parts or assemblies calling for stamping, machining, heat-treating, or grinding. Send sketch or blueprint.

PRODUCTION DOUBLED?

In the Case Shown Below Machine Production was Practically Doubled!

Another Cortland War Production Test in the plant of a manufacturer of grinding machines . . . Cortland Chucks and Segments against another brand of Sectored Cylinder Wheels . . . on a Blanchard No. 18 Vertical Surface Grinder; wheel speed 705 R.P.M.

WORK: Plate for Diamond Holder—cast iron; 76.5 sq. in. per piece; 7 pieces per table load.

Here are the Production Test results. Note the tremendous difference in performance of Cortland Chucks and Segments over the brand formerly used.

Detail	CORTLAND Chuck and Segments	*Competitive Brand of Sectored Cylinder*
Cubic inches of stock removed per inch in height of segments	1606.4	739.5
Ampere readings	85	66 - dress
Dressings necessary	None	5
Work heat?	No	No
Grinding time	6 min.	11 min.

In addition to the greatly increased machine production, note that more than double the amount of stock was removed per unit of abrasive.

Why not investigate the possibility of improving the quality and quantity of your vertical spindle surface grinding production with Cortland Chucks and *Diagonal Shearing* Segments? Write for latest illustrated bulletin giving the complete story of Cortland's amazing performance.

CORTLAND GRINDING WHEELS CORP.
7 Cortland Street Chester, Massachusetts

Diagonal Shearing with Varying Contact Means Better Surface Grinding

A true segment, the grinding surface has narrow ends that *start* the work with minimum shock and resistance. Straight inner edge of segment passes diagonally across work with a *shearing* action that *cuts* and *removes* the metal. Varying contact area insures longer exposure to coolant—decreases heat—reduces segment wear—conserves power.

Chucks and Segments

CLEAN STRIP STEEL BEFORE ANNEALING AND ELECTRO-TINNING

by using FAST

OAKITE COMPOSITION No. 90

When strip steel speeds along at a thousand or more feet per minute through the large installations necessary for annealing or electro-tinning this metal, unusually FAST, THOROUGH degreasing is a prime requisite. That's why we say ... to obtain the essential, CHEMICALLY-CLEAN surfaces, use quick-acting Oakite Composition No. 90 in your scrubber or washing machine.

You will find that this specially designed anodic degreasing material SPEEDILY and COMPLETELY removes rolling oil, insoluble smut, dirt and other accumulations from steel surfaces. Is also excellent for removal of smut deposits after the acid pickle.

Technical Service FREE!

Our nearby Technical Service Representative will gladly show you how Oakite Composition No. 90 can be utilized in handling this work effectively in your plant. Write today to have him call ... there's no obligation, of course!

MATERIALS & METHODS FOR EVERY CLEANING REQUIREMENT

New Order Sets Procedure In Sales of Idle Stocks

Washington

• • • To facilitate the work headed up by W. L. Clayton, Surplus War Property Administrator under the Baruch plan, the WPB on Feb. 29 revised PR-13 to provide priority procedure for disposing of not only raw materials but all types of property classified as idle or excess.

The revised regulation establishes procedures under which materials may be sold by persons not regularly in the business of selling such materials. While most sales of this kind will be sales of frozen, idle, or excess materials, the regulation also covers sales from inventories.

When idle materials are on hand because a business has been converted to war work; stopped or limited by WPB orders; or contracts have been cancelled or changed, idle or excess materials may be sold only under the rules defined in the regulation. The regulation also controls liquidation, bankruptcy, general auction, and other special sales.

The new rules will govern sales of all idle and excess materials, with three exceptions, which are: (1) scrap; (2) rationed products, which are under the control of some governmental agency other than WPB; and (3) foods, petroleum and petroleum products, including natural liquified petroleum gases, etc.

The regulation contains two lists. List A indicates those industral (raw) materials to which specific rules for special sales apply. The list also indicates what special rules apply to the materials listed. Industrial materials not listed may be sold freely to anyone. List B includes those "finished products" to which specific rules for special sales apply. Finished products not on List B may be sold to anyone who produces such a product in the form in which the holder possesses it or to a wholesaler whose regular business is selling such a product in whole or in part, from stock or inventory. Such sales may be made freely. Sales of "finished products" may also be made to anyone permitted to use such products under WPB rules on a purchase order of AA-5 or better.

Authorization to make a special sale of controlled materials may be granted (a) where the person has an allotment of controlled materials and (b) where the person has no allotment. In the first instance, the person when granted permission to buy idle and excess stocks need not charge his allotment account with the amount of materials so acquired. In the case of copper in controlled material form, permission may be given only if the buyer has an authorized production schedule.

Controlled materials purchased under the special sales procedure must be used under WPB rules. List A and B will be revised monthly.

Year-End Scrap Stocks Total 6,458,000 Tons

Washington

• • • Stocks of iron and steel scrap at plants of consumers, suppliers, and producers at the end of December, 1943, approximated 6,458,000 gross tons, according to the Bureau of Mines, U. S. Department of Interior. Pig iron stocks totaled 1,404,000. This represents an increase over the stocks on Nov. 30, 1943, which totaled 6,391,000 tons, accounted for mainly gains in stocks in dealers yards, the observance of the Christmas holiday by consumers, and the strikes late in December at steel plants. The latter factors caused a reduction in consumption.

Summary of Stocks and Consumption of iron and steel scrap and pig iron, Gross Tons

	Stocks at End of Month			Consumption During Month		
	Scrap			Scrap		
Month	Purchased	Home	Pig Iron	Purchased	Home	Pig Iron
January	5,370,000	1,464,000	1,302,000	1,942,000	2,550,000	4,515,000
February	5,354,000	1,517,000	1,370,000	1,857,000	2,321,000	4,162,000
March	5,343,000	1,507,000	1,350,000	2,102,000	2,685,000	4,660,000
April	5,416,000	1,502,000	1,327,000	2,019,000	2,623,000	4,423,000
May	5,414,000	1,491,000	1,328,000	2,053,000	2,670,000	4,511,000
June	5,385,000	1,531,000	1,374,000	1,944,000	2,549,000	4,239,000
July	5,318,000	1,542,000	1,344,000	1,964,000	2,606,000	4,473,000
August	5,237,000	1,541,000	1,363,000	1,975,000	2,711,000	4,620,000
September	5,067,000	1,546,000	1,385,000	1,978,000	2,679,000	4,571,000
October	4,978,000	1,478,000	1,343,000	2,051,000	2,779,000	4,706,000
November	4,896,000	1,495,000	1,332,000	2,006,000	2,575,000	4,465,000
December	4,939,000	1,519,000	1,404,000	1,906,000	2,543,000	4,481,000

Alloy Scrap Utilization Recommended

REPORTING to a recent Ferrous Foundry Industry Advisory Committee meeting, on a series of tests run by a foundry looking to the utilization of the surplus alloy scrap supply, Victor E. Zeng said that these tests proved extremely satisfactory.

Being faced with the problem of using their own remelt, plus 8 plus alloy turnings in alloy melts under Order M-21-a, electric foundries with smaller melting units frowned on using additional alloy scrap. The melting of these turnings imposed considerable hardship and chance, due to bulk (low poundage per cu. ft.) which caused back charging with loss of time and hazards from flying molten metal; erratic analysis, which gave difficulty in figuring analysis, and thereby limited the amounts of alloy steels that could be used in conjunction with them, and retained cutting oils, which increased carbon content with increased melting and refining time, as well as possibilities of sulphur pick-up.

Late in November a 90-day relief from M-21-a was granted to experiment on making alloy steels with the maximum alloy steel scrap charges. The following is a resume of 100 such heats melted in a period of 17 days.

Scrap Charge	lb.	Per cent
Total scrap	1,171,900	100.0
Foundry remelt alloy	490,500	41.9
Foundry remelt carbon	24,500	2.1
Purchased alloy	544,900	46.5
Purchased carbon	112,000	9.5

Use of some carbon steel scrap is necessary to adjust chemical compositions, as these heats are melted without the use of any additions of virgin alloy.

When first starting this procedure, considerable difficulty was encountered in adjusting charges to maintain a desired composition. However, it is felt that this is now well overcome, and charging instructions are given so as to maintain a specific range that meets all physical requirements.

The chemical range is listed, with the percentage of "withins," for each major element.

Element:	Carbon	Manganese	Nickel	Chromium	Molybdenum
Range	0.27 to 0.37	0.75 to 0.85	0.60 to 0.90	0.40 to 0.60	0.17 to 0.27
Withins per cent	93	92	67	98	95

It will be noted that nickel is the hardest element to control. This difficulty is caused by variations of as much as 0.3 per cent of this element in scrap steels when purchased under the same specifications, while other elements maintain a much narrower range. To show chemical variation, typical average analyses of 11 cars of scrap received during this trial are given.

Car	Specifications	Nickel	Chromium	Molybdenum
A	SAE 4340	1.62	0.62	0.29
B	SAE 4340	1.84	0.66	0.24
C	SAE 4340	1.86	0.68	0.25
D	SAE 4340	1.68	0.60	0.19
E	SAE 4340	1.56	0.58	0.35
F	NE 8600	0.42	0.32	0.32
G	NE 8600	0.50	0.36	0.33
H	NE 8600	0.38	0.33	0.20
I	Moly Plate	....	....	0.29
J	Moly Plate	....	....	0.30
K	Moly Plate	....	....	0.21

Brinell Hardness	Tensile	Yield	Elongation, per cent	Reduction of Area, per cent
207	100,000	75,000	25	45
217	105,000	77,000	23	45
228	110,000	85,000	19	45
241	115,000	90,000	19	42
255	120,000	95,000 to 100,000	17	40
269	125,000 to 130,000	105,000	17	35

Sampling procedure has been found important in the maintenance of proper scrap piles and charges. When cars contain only one type of scrap, two samples are selected and analyses run in duplicate on each sample. When several types of scrap are received in one car, two samples of each type are analyzed in duplicate and the entire lot averaged.

Scrap is then grouped according to the average analysis. For example, in the preceding analyses three groups were used:

Scrap is charged by magnet into charge buckets, in accordance with instructions issued by the laboratory. Charging instructions vary according to analysis of scrap and the quantity of foundry alloy remelt to be consumed. A typical charge is given below:

	lb.
Foundry alloy remelt scrap	4,000
Moly plate (purchased) scrap	1,000
SAE 4340 (purchased) scrap	4,000
NE 8600 (purchased) scrap	1,000
Carbon (purchased) scrap	2,000
	12,000

This type of melting has produced a steel that melts all QQS-681-B, 4B series and 4C series up to 4C3, consistently and regularly, by variation of heat treatment according to the physical properties desired. Since using this practice, the Ordnance Department after testing 20 consecutive heats placed this foundry on a quality control basis for 4C2 steels. A fairly close control of physical properties can be obtained by controlling the Brinell hardness as shown by the average results obtained from regular production tests on oil quenched and drawn steels.

Besides the economy in conserving alloys from this type of melting, there are other economies such as decreased melting time, decreased power consumption, easier operation, and more consistent results from less experienced melters.

By calculations based on average finished analysis and the ratio of scrap to foundry alloy returns, it was estimated that from these 272 tons of alloy scrap 4884 lb. of chromium, 5451 lb. of nickel and 1300 lb. of molybdenum were conserved and utilized to a good advantage.

This is further substantiated by the fact that the foundry is now starting to return to WPB alloy allocations that will not be required.

From this test run, it is believed that 30 to 40 per cent of alloy scrap (purchased) can be melted in addition to foundry returns, depending upon the alloy specification and the analysis of the scrap available. At present schedules, the foundry contemplates using 500 tons of alloy scrap each calendar month.

Plane Output Hits Record

• • • **Record** production in the aircraft industry, with planes being made at a rate 350 per day, was accomplished during February, according to a report by Charles E. Wilson.

Total airframe weight hit an all-time high of 93,500,000 lb. with bombers, cargo carriers, fighters and tactical planes making up 84 per cent of production. The number of planes accepted by the government was 8760 for the month.

"Manufactured Scrap"

THIS HEAPED UP HANDFUL contains 3 lbs. of head trimmings obtained from 100 ¾" x 6" hexagon head bolts made by cold forging on the most modern bolt-making equipment in a Lamson & Sessions plant. ONE BOLT PER SECOND can be produced by this method.

WASTE OF RAW MATERIALS RATIO is 25:1 in this instance MADE BY EITHER METHOD the finished bolt weighs 13½ oz.

THIS WHEELBARROW contains 75 [illegible] of turnings made in producing 100 ¾ 6" hexagon head bolts on the most [illegible] ern six spindle automatic screw mac[illegible] in a Lamson & Sessions plant. ONE B[illegible] PER MINUTE can be made by this meth[illegible]

. . PRODUCED IN MAKING A BOLT EATS UP TIME, EATS UP MONEY . . . AND EATS UP PRECIOUS MATERIAL!

Whether the material for making bolts is aluminum, copper alloy, alloy steel or just plain carbon steel—there is sure to be a needless waste of raw material required for any given quantity of bolts made by milling as compared with making those same bolts by cold forging.

Lamson & Sessions makes bolts by both methods—and always has—but the trend toward cold forging bolts is now so strong that virtually 98% or more of our entire production is by hot or cold forging, otherwise known as upsetting.

Of the two methods of bolt manufacture—milling and upsetting—milling is the slowest and most exacting method. It is very accurate, but very slow; very expensive because close personal supervision of the machine is essential and it is very wasteful of raw materials.

By weighted averages, the waste factor in manufacture by milling as opposed to production by upsetting (cold forging) is about 20:1. The waste (chips produced by milling) ordinarily cuts away about 50% or more of the raw material. We scrap less than 5% of the raw material when we make bolts by upsetting.

Cold forging and rolling threads produces bolts to such close tolerances that the aircraft industry has accepted them after exacting tests had demonstrated them equivalent or superior to the milled product.

It may be made axiomatic—any bolt that *can be made* by hot or cold forging, *should be made* by hot or cold forging, if the quantity required is large enough to justify making the necessary forging dies.

At left is an actual example of scrap produced per 100 bolts (¾"x6", hexagon head) as made by both milling and cold forging.

Keep this in mind when you design for assemblies for war production—*and for post-war manufacturing too.*

THE LAMSON & SESSIONS COMPANY, General Offices, Cleveland, O.

"BOLTS ARE IMPORTANT!"—24-page booklet of currently useful information for buyers of headed and threaded products, and describing Lamson & Sessions' specialty fastenings which have wide industrial applications—*now, and in the post-war period.*

"THE LAMSON BLUE BOOK"—is our standard Catalog of standard products excepting our Aircraft products.

"BOLTS, NUTS & SCREWS"—70 pages of technical and practical information. First copy gratis, requested on your letterhead. Additional copies one dollar each.

"SIMPLIFIED STOCK LIST"—Of bolts, nuts and screws, conforming to latest revisions of the Office of Price Administration, and of great value in showing you in what ratio quantities of various standard products are kept in stock for deliveries, by your jobbers and in our own (and other bolt manufacturers') warehouse stocks.

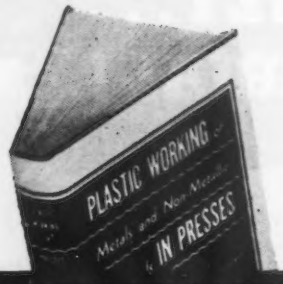
KNOW PLASTICS!

Read the new Crane book—



PLASTIC WORKING
of Metals and Non-Metallic Materials
IN PRESSES
(3rd Edition)

By E. V. Crane

Chief of Development Engineering, E. W. Bliss Company, Brooklyn, N. Y.

The successful engineer of tomorrow is studying PLASTICS today! Of incalculable help in furthering his ambitions is CRANE'S newly revised and enlarged edition of PLASTIC WORKING IN PRESSES.

As B. J. Johnson of Detroit University and the Murray Corp. of America says, "Your book includes such a wealth of theory and physical data that one can solve practically any problem in press assignment with its help."

Briefly, the new "Crane" tells what can be and is being done with new materials and products. The original discussion of sheet metal working and forging now covers powdered metals, synthetic plastic powders, ceramics, papers, sheet plastics and laminated materials of many types. From this orderly presentation of facts the engineer is able to draw up well-coordinated rules which assure successful processing and production.

The Appendix contains charts for quick computation of shearing, drawing, ironing, coining and forging pressures, work, speeds, press flywheel capacities, pressure capacities, and other helpful tables.

540 Pages *Illustrated* **$5.00**

ON APPROVAL COUPON

JOHN WILEY & SONS, Inc.
440 FOURTH AVENUE, New York 16, N. Y.

Please send me a copy of Crane's PLASTIC WORKING IN PRESSES on ten days' approval. At the end of that time, if I decide to keep the book, I will remit $5.00 plus postage; otherwise I will return the book postpaid.

Canada Drops More Metal Use Controls

Toronto

• • • As of March 1, the Canadian Steel Controller, dropped all control regulations pertaining to the sale of merchant pig iron, with the result that melters now are permitted to place orders direct with producers of their own choice instead of first sending orders to Ottawa for approval as has been the case for the past couple of years. No shortage of pig iron is reported in Canada. On the contrary most producers are carrying good stock piles and are in a position to give prompt shipment on new orders.

Slowing down in Canada's war production program with only minor improvement in civilian production schedules is responsible for curtailment in iron and steel production. With the single exception of sheets, in connection with which Canadian mills are maintaining capacity production and large tonnages continue to pour in from the United States, there is no shortage of steel in this country. While Ontario plate mills are fairly well booked to the end of April, the mills at Sydney, N. S., are operating only about one-third capacity. On bars, structural shapes, and most other types of steel, many producers have unfilled capacity and are seeking new customers.

Canadian Iron, Steel and Ferro Alloy Output

	Net Tons Produced		
	January, 1944	December 1943	January, 1942
Pig Iron	132,128	137,256	138,240
Ferro Alloys	16,495	17,038	18,838
Steel	242,186	227,882	207,008

More steel now is being released for civilian activities and at frequent intervals new items of manufacture are being added to the list that may be produced. H. H. Foreman, administrator of fabricated steel and nonferrous metals, in the Wartime Prices and Trade Board, announced that restrictions on manufacture and distribution of metal windows have been lifted and the manufacture of venetian blinds, prohibited since September, 1942, again is permitted.

COMING EVENTS

March 14, 15—National Association of Waste Materials, Inc., New York.
March 27, 28—American Society of Tool Engineers, Philadelphia.
March 30, 31—American Gas Association War Conference, Rochester, N. Y.
April 2 to 5—The American Ceramic Society, Inc., Pittsburgh.
April 5, 6, 7—SAE National Aeronautic Meeting, New York.
April 12 to 15—The Electrochemical Society, Inc., Milwaukee.
April 17, 18—American Zinc Institute, St. Louis.
April 20, 21—American Institute of Mining & Metallurgical Engineers, Pittsburgh.
April 25 to 28—American Foundrymen's Association, Buffalo.
May 1, 2—Westinghouse Machine Tool Electrification Forum, Pittsburgh.
May 8—Association of Iron & Steel Engineers, spring conference, rolling mill committee, Pittsburgh.
May 25—American Iron and Steel Institute, New York.
June 5, 6, 7—SAE National War Materiel Meeting, Detroit.
Oct. 5, 6, 7—SAE National Aircraft Engineering & Production Meeting, Los Angeles.
Oct. 5, 6—American Institute of Mining & Metallurgical Engineers, Pittsburgh.
Oct. 16, 17, 18—American Institute of Mining & Metallurgical Engineers, Cleveland.
Oct. 27, 28—American Institute of Mining & Metallurgical Engineers, Columbus, Ohio.
Dec. 4, 5, 6—SAE National Air Cargo Meeting, Chicago.
Jan. 8 to 12, 1945—SAE Annual Meeting, Detroit.

Mulac Named to WPB Tools Division Post

Washington

• • • **Anthony A. Mulac** has been appointed an assistant director of the WPB Tools Division in charge of the Industrial Specialties Branch. Mr. Mulac has long been associated with the cutting tool industry and came to Washington from the United Drill & Tool Co. of Chicago, with which he has been associated in a consulting capacity.

Mr. Mulac has been associated with WPB and its predecessor organization OPM, since Aug. 19, 1941. He originally gave his time largely to cutting tool problems. Since September, 1943, he has been chief of the Industrial Specialties Branch, which includes sections handling abrasives, chain, cranes and hoists, metal cutting tools, foundry equipment and supplies, gages and precision measuring tools, heat treating equipment, portable power tools and other industrial supplies.

Eight Point Plan for Small Firms Outlined

• • • **Picturing** small business as being in a perilous position now and needing strong government assistance, Maury Maverick, chairman of the Smaller War Plants Corp., speaking in New York, March 1, outlined an eight-point program to help protect "the little business man." The platform included:

1. Enforcement of anti-trust laws.
2. Elimination of cartels.
3. Financial assistance to small business, aided by present banking facilities.
4. Preference in allocations of materials after the war.
5. No quotas on production of small plants.
6. No curbs on business entry of any line it wishes.
7. First call for small plants on Government-owned tools and equipment.
8. Technical assistance in a manner comparable to that given farmers by the Department of Agriculture.

Maverick warned that returning veterans must be given jobs or the nation faces a dictatorship. He charged that banking interests have not fully planned for the best interests of small business. He declared that many Army cutbacks have been affecting small businesses first.

Idle Tool Holders Must File Monthly WPB Reports

Washington

• • • **To effect an orderly** redistribution of idle tools, WPB has inaugurated a monthly report on idle machine tools. The first report is to be filed by April 1 and there will be a monthly report thereafter. The general instructions accompanying the report form WPB-3475, state:

1—*Who must file* — Every person having physical possession of any government-owned machine tool which is idle, and which had an original cost of $500 or more, must report it on form WPB-3475 to the WPB field office within whose jurisdiction the machine tool is located.

2—*When to file*—The first report is to be submitted on or before April 1, 1944, and may be prepared as of any date within the proceding 30 day period. Succeeding reports must be prepared as of the same date for each month thereafter in which there are any additions or deletions to the list of idle tools. Succeeding reports must be filed within 10 days of the date as of which the report is prepared. Supplementary reports need show only additions or deletions.

3—*Separate reports for each Plancor or facility contract number.*—Use a separate form WPB-3475 to report all machine tools pertaining to each different Plancor number or facility contract involved.

The term "government-owned machine tool" shall mean any power driven mechanism whose primary use and function is to form or shape metal by means of cutting, grinding, shaping, or forming, in which machine tool the United States Government or any department, agency, or establishment thereof has acquired any title, right, or other possessory or property interest.

For purposes of this report, a machine tool is idle if it is not now working on war contracts and if there is no definite work on war contracts scheduled for such machine within the next 30 days.

Cancelled Contract Material Values Explained by OPA

Washington

• • • **On receipt of a** contract termination notice, a manufacturer may have in his plant certain articles which are completed or in process of production. The manufacturer is then required to halt shipments and cease production and is permitted to file a claim for completed articles that are undelivered and for incompleted articles. The manufacturer may be asked to retain these articles and to make an allowance for the metal involved. There are specified provisions for the manufacturer, in determining this metal allowance to be deducted from his claim, for assigning values in excess of the maximum price which would be applicable on a sale of the particular material as scrap.

In such cases, where title to the undelivered articles is retained by the manufacturer, the transaction in question is not a sale of scrap metals, according to the OPA. The value assigned to the metal is but one of the several factors considered in arriving at the amount of the settlement to be received by the manufacturer. In determining the amount of this metal allowance, the parties are not limited by the various maximum price regulations which are applicable to sales of scrap metals. This interpretation applies only to the termination of sales contracts and not to toll contracts.

POSITION OPEN

for Alloy Steel Foundry **PLANT MANAGER**

Modern, well-equipped alloy steel foundry, many years in business, has position open for plant manager capable of taking entire charge of production. Prefer man, 35 to 50 years old, with metallurgical engineering training and experience in the production of heat resisting and corrosion-resisting castings. Good salary and bonus arrangement and real opportunity that will come with post-war developments, which had been started but were interrupted by war production.

ADDRESS BOX B-300, care *The Iron Age*, 100 E. 42nd St., New York 17

MACHINE TOOLS

. . . News and Market Activities

Close Screening of Orders Praised, Blamed

Cleveland

• • • **The machine tool** market continues to register a steadily slackening trend. Orders are considered very spotty and the overall demand has been quite weak and slowly declining. Special tool orders have held up volume somewhat but are also slowing perceptibly. Sudden rush orders for certain types of tooling cause spurts but no flow of business is in sight. Subcontracting is maintaining employment in most plants, however.

One of the most serious complications in the sales of new machine tools at present appears to be the closeness with which WPB is screening requests. The majority of requests for new tools are not being approved and are for the most part being diverted to acceptance of slightly used or government owned tools listed as idle and excess. There is considerable complaint from machine tool builders on this score but also a certain amount of praise of the WPB's efforts.

Realizing that every additional new tool built now will add to the industry's problem of surpluses after the war the close screening of orders by WPB is commended by many tool manufacturers. Those who favor the WPB's action state that manufacturers are in a better position now to absorb the punishment of business diversion than in the period after the war. The other school of thought would favor building of every machine requested as a means of supporting the industry at present with the future of the business to rest in the industry's hands alone after the war.

After more than two years of functioning it is only being learned now that the wording of the machine tool pool contracts is so vague and open that any decision as to who must pay the storage charges on pool tools is just a matter of individual interpretation on the part of the government agency involved.

A recent official report on the growth of the machine tool industry in Australia gives a pertinent tip on what the prospects for post-war exports to Australia might be for American machine tools. Since 1939 Australian facilities have grown from five machine tool plants building less than 100 machines per year to about 75 plants which since the beginning of the war have built and are building on upwards of 20,000 finished machine tools. As a market, saturation appears as evident there as here. Self-sufficiency has been the impetus behind Australian development, the report intimated.

In addition, it was noted, Australia now has 188 plants engaged in the manufacture of small tools and gages which are producing these products at the rate of about 26,000 daily.

•

Westinghouse Machine Tool Forum

• • • **Requirements of** electrical equipment for high speed milling will be explained by prominent machine tool engineers as one of the features of the 1944 Westinghouse Machine Tool Electrification Forum to be held at the William Penn Hotel, Pittsburgh, on May 1 and 2. Many of the problems facing machine tool manufacturers and users today and in the future, will be discussed by recognized experts during the two day session. This will be the ninth annual forum sponsored by Westinghouse Electric & Mfg. Co. to provide information on electrical problems for machine tool engineers and executives of machine tool builders. A portion of the forum time will be turned over to the National Machine Tool Builders' Association for a session on post-war standards for electrical equipment on machine tools. An innovation this year will be the parallel sessions during the afternoon of the first day during which papers of commercial interest will be presented at one session and papers of engineering interest at the other.

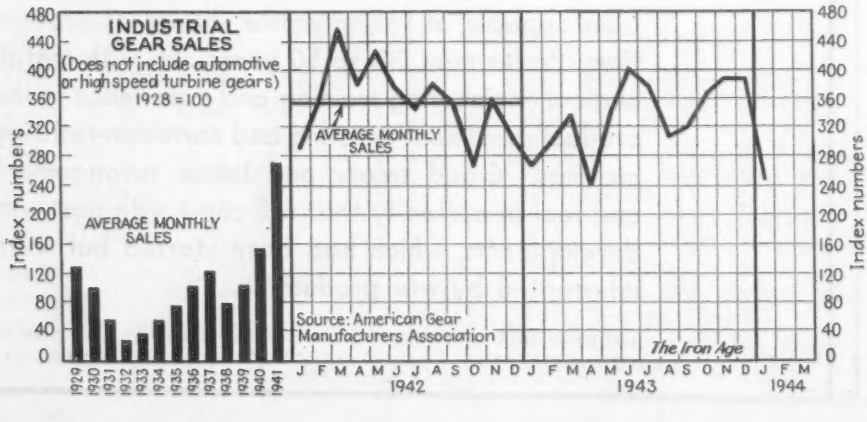
•

Machine Tool Prices Unchanged

• • • **The Bureau of** Labor Statistics' index of prices of standard (non-specialty) machine tools was again unchanged for the fourth quarter of 1943 at 118 per cent of the August, 1939, average, the level prevailing since September, 1941. In January, 1942, the Office of Price Administration fixed prices of machine tools at the October, 1941, average. The level thus established by regulation continued for most machine tools the prices informally agreed upon several months before, but caused a roll-back in prices for certain others. As a result of this action slight price decreases were reported in February, 1942, for radial drills, engine lathes and punch presses, but these changes were not large enough to affect the general average.

January Gear Sales Drop Sharply

. . . The gearing industry as represented by the members of the American Gear Manufacturers Association shows a decrease of 36.5 per cent in the business booked in January, as compared with December. The January index figure was 246 as compared with 387 for December.



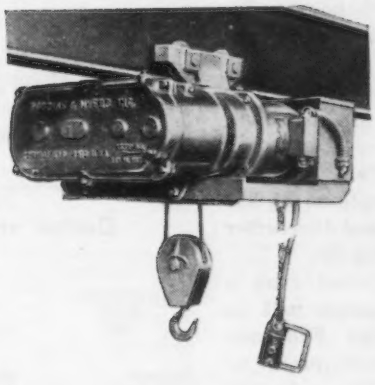
"SORRY...DELAY"

"ON ORDER...WAITING"

"60 DAYS"

"MATERIAL...PRIORITY"

THIS SHOULDN'T HAPPEN TO YOU!



The R & M Type F½ Hoist has 1000 — 2000-pound capacity. It is provided with pendent, push-button control. A step forward in improved design, better materials, and manufacturing economies that provide a better hoist at lower cost in both purchase price and operation.

Make the Most of Your Manpower, Now... Get R&M Hoist Delivery Promptly!

Making limited (and often inexperienced) manpower go further, R & M Hoists give you the equivalent of several extra hands. These hoists permit you to move materials faster and easier with less help, and prompt delivery of them gives you those benefits . . . now. Two of the many R & M Hoists available for quick delivery are shown here.

The R & M Type F Hoist has 1000 — 15,000 - pound capacity. Push-button control is standard. Operating with low headroom and handling loads from any angle with perfect balance, the Type F Hoist makes a one-man job of many otherwise cumbersome operations.

Begin, today, to enjoy the benefits of simpler, more profitable materials handling

NON-FERROUS METALS

. . . News and Market Activities

Bonus Payments for Tungsten Eliminated

• • • **Premium price payments** to tungsten producers will be discontinued April 30, 1944, the WPB announced. Notice of the discontinuance will be mailed by the Metals Reserve Co. so as to give 30 days' time allowance, as provided in the contracts between producers and the Metals Reserve Co.

This action was taken because adequate stockpiles have been built up and current domestic production and imports are now more than sufficient to meet current consumption demands.

Those tungsten producers who qualified as "eligible" were paid $30 per unit (20 lb.) of contained tungsten for their ore. This premium price (which is $6 above the market price of $24) was set, to secure needed tungsten from marginal mines, in November, 1942.

Under the new program, domestic buying by MRC will continue at $30 per unit until April 30 and thereafter at $24 per unit until June 30.

It was further explained that a similar curtailment program will be followed by the Foreign Economic Administration in the procurement of tungsten from abroad. This reduction in price both in this country and abroad and the decrease in domestic production and imports will be made effective coincidentally by the Metals Reserve Company and by the Foreign Economic Administration.

Nicaro Starts Production

• • • **In his annual report,** L. M. Williams, president of Nicaro Nickel Co. and Freeport Sulphur Co., the parent company, announced the beginning of production at two new nickel plants operated by Nicaro for DPC.

The plants are located at Oriente Province, Cuba, and at Wilmington, Del. Metals Reserve Co. will receive all the nickel made at these plants.

Ore from open strip mines are treated at the Cuban plant where it is crushed, dried and ground to a very fine mesh in hammer and ball mills. The dry dust is then reduced and bleached in an ammonia solution from which the nickel is precipitated in the form of nickel carbonate. The next step is calcining the carbonate to nickel oxide which is shipped to the Wilmington plant for futher refining.

The cost of the Cuban and American plant was $33,500,000.

Scrap Stocks Down

• • • **In the non-ferrous scrap** metal industry, the December summation showed an increase in dealers' receipts and stocks on hand, but a decrease in dealers' shipments to consumers, according to the U. S. Bureau of Mines.

The increase in receipts was slight, but stocks mounted 7 per cent over the November closing inventory, while the decrease in shipments to consumers, from 81,944 tons in November to 77,174 tons in December, registered a decline of about 6 per cent.

Receipts of copper and brass during December showed an increase over November of 3135 net tons or approximately 8 per cent. At the same time dealers' shipments to consumers declined from 39,595 tons in November to 38,994 tons, the lowest point since September and the third lowest point during the entire year. Dealers' receipts in December were above average, but shipments to consumers were almost 6 per cent below the average for the year. It is also to be noted that shipments to consumers for the last six months of 1943 were consistently lower than for the preceding six month period.

The breakdown of various grades of copper and brass scrap shipped to consumers was as follows:

	Net Tons
Rod ends and rod turnings	3,917
Brass mill clips, punchings, etc.	2,587
Unalloyed copper scrap	8,437
Composition and bronze (OPA Group 2)	9,677
Yellow brass (OPA Group 3)	4,087
Radiators	1,195
All other copper-base scrap	9,094
Total copper and brass scrap	38,994

Dealers' stocks of non-ferrous scrap metals in 1943, in net tons

INVENTORY DATE 1943	Type of Non-Ferrous Scrap Metal						Total

Aluminum

(Cents per lb., subject to extras on gage, size, temper, finish, factor number, etc.)

Tubing: 2 in. O.D. x 0.065 in. wall 2S, 40c. (½H); 52S, 61c. (O); 24S, 67½c. (T).

Plate: 0.250 in. and heavier: 2S and 3S, 21.2c.; 52S, 24.2c.; 61S, 22.8c.; 24S, 24.2c.

Flat Sheet: 0.188 in. thickness: 2S and 3S, 22.7c. a lb.; 52S, 26.2c.; 61S, 24.7c.; 24S, 26.7c.

2000-lb. base for tubing; 30,000-lb. base for plate, flat stock.

Extruded Shapes: "As extruded" temper; 2000-lb. base, 2S and 3S, factor No. 1 to 4, 25.5c.; 14S, factor No. 1 to 4, 35c.; 17S, factor No. 1 to 4, 31c.; 24S, factor No. 1 to 4, 34c.; 53S, factor No. 1 to 4, 28c.; 61S, factor No. 1 to 4, 28½c.

The factor is determined by dividing perimeter of shape by weight per lineal foot.

Wire Rod and Bar: Base price; 17ST and 11ST-3, screw machine stock. Rounds: ¼ in., 28½c. per lb.; ½ in., 26c.; 1 in., 24½c.; 2 in., 23c. Hexagonals: ¼ in., 34½c. per lb.; ½ in., 28½c.; 1 in., 25½c.; 2 in., 25½c. 2S, as fabricated, random or standard lengths, ¼ in., 34c. per lb.; ½ in., 25c.; 1 in., 24c.; 2 in., 23c. 24ST, rectangles and squares, random or standard lengths. 0.093-0.187 in. thick by 1.001-2.000 in. wide, 33c. per lb.; 0.751-1.500 in. thick by 2.001-4.000 in. wide, 29c.; 1.501-2.000 in. thick by 4.001-6.000 in. wide, 27½c.

Magnesium

Sheet, rod, tubes, bars, extruded shapes subject to individual quotations. Metal turnings: 100 lb. or more, 46c. a lb.; 25 to 90 lb., 56c.; less than 25 lb., 66c.

NON-FERROUS SCRAP METAL QUOTATIONS

(OPA basic maximum prices, cents per lb., f.o.b. point of shipment, subject to quality, quantity and special preparation premiums)

Muntz metal condenser tubes	7.00
Plated brass sheet, pipe reflectors	6.50
Manganese bronze solids	7.25[1]
Manganese bronze solids	6.25[2]
Manganese bronze borings	6.50[1]
Manganese bronze borings	5.50[2]

OPA Group 4

Automobile radiators	7.00

OPA Group 5

Refinery brass	5.00*

*Price varies with analysis. [1] Lead content 0.00 to 0.40 per cent. [2] Lead content 0.41 to 1.00 per cent.

Other Copper Alloys

Briquetted Cartridge Brass Turnings	8.625
Cartridge Brass Turnings, Loose	7.875
Loose Yellow Brass Trimmings	7.875

Aluminum

Plant scrap, segregated

2S solids	9.00
All other solids	8.50
Borings and turnings	
W'rt alloys (17S, 18S, 32S, 52S)	7.50
High grade alloys	7.00
Low grade alloys	6.50

Plant scrap, mixed

All solids	7.50
Borings and turnings	5.50

Obsolete scrap

Pure cable	9.00
Old sheet and utensils	7.50
Old castings and forgings	8.00
Pistons, free of struts	8.00
Pistons, with struts	6.00
Old alloy sheet	7.00

For old castings and forgings, pistons, sheets, add ½c. lb. for lots 1000 to 19,999 lb.; for other scrap add 1c.; for lots over 19,999 lb. add 1½c. a lb.

Magnesium

Segregated plant scrap

Pure solids and all other solids, exempt	
Borings and turnings	8.00

Mixed, contaminated plant scrap

Grade 1 solids	11.00
Grade 1 borings and turnings	7.00
Grade 2 solids	9.00
Grade 2 borings and turnings	5.00

For lots over 1499 lb. add 1c. per lb.

Zinc

New zinc clippings, trimmings	7.25
Engravers', lithographers' plates	7.25
Old zinc scrap	5.75
Unsweated zinc dross	5.80
Die cast slab	5.80
New die cast scrap	4.95
Radiator grilles, old and new	4.95
Old die cast scrap	4.50

Lead

Deduct 0.55c. a lb. from refined metal basing point prices or soft and hard lead inc. cable, for f.o.b. point of shipment price.

Nickel

Ni content 98+%, Cu under ½%, 26c. per lb.; 90 to 98% Ni, 26c. per lb. contained Ni.

ELECTROPLATING ANODES AND CHEMICALS

Anodes

(Cents per lb., f.o.b. shipping point)

Copper: Cast, elliptical, 15 in. and longer	25⅛
Electrolytic, full size	22⅞
cut to size	30⅛
Rolled, oval, straight, 15 in. and longer	23¼
Curved	24¼
Brass: Cast, 82-20, elliptical, 15 in. and longer	23⅝
Zinc: Cast, 99.99, 16 in. and over.	16¼
Nickel: 99% plus, cast	47
Rolled, depolarized	48
Silver: Rolled, 999 fine per Troy (1-9) oz., per oz.	58

Chemicals

(Cents per lb., delivery from New York)

Copper cyanide, tech., 100-lb. bbls. 1-5	5.65
Copper sulphate, 99.5 crystals, bbls.	13.00–13.50
Nickel salts, single, 425-lb. bbls.	34.00
Silver cyanide, 100 oz., lots	40.82–41.125
Sodium cyanide, 96% dom., 100-lb. dms.	0.15
Zinc cyanide, 100-lb. dms.	33.00
Zinc, sulphate, 89% crystals, bbls.	6.80

SCRAP

. . . News and Market Activities

Schwartz Lauds Canada's Efforts in Scrap Campaigns

• • • Too frequently in America's drive to get out more scrap for use in the nation's steel plants, the aid afforded by allied nations in obtaining this needed scrap is overlooked. For example, it was pointed out by Benjamin Schwartz, chief of the scrap metals section of the Foreign Economic Administration, that the United States imported scrap metal from 30 countries during 1943.

Speaking before the Canadian Secondary Materials Association at Montreal last week, Mr. Schwartz lauded the Canadian contribution of scrap to the United States during 1943. He said, in part:

"The scrap metal trade of Canada has played an important part in fulfilling the strategic raw material requirements of the United Nations. With reference to the United States alone, the contribution of Canada in the form of scrap iron and steel and nonferrous scrap metals has been substantial. Although figures cannot be quoted, it is pertinent to note that Canada is at the top of the list of 30 countries from which scrap metals were imported into the United States."

Interesting also to note is the fact that the machinery established between the Canadian and American governments for the clearance of exports and imports of scrap has functioned smoothly. The volume of scrap business was distributed over a wide base of dealers and it was possible to facilitate private trading between dealers in Canada and dealers and consumers in the United States without the necessity of direct government purchases.

•

PITTSBURGH — Snow and sleet this past week here will not slow deliveries up to the point where any acute shortages will result. Prices are firm in this area, but short turnings are still coming from Detroit without the springboard. Rejections are not as heavy on material as was the case a month ago. Apparently as result of heavy rejections several weeks ago, dealers and consumers have tightened up on inspections.

•

PHILADELPHIA—Mill stocks of open hearth grades are low and there seems no indication that they will be increased greatly. One mill, however, is still holding up some of its scrap shipments. Some consumers have placed restrictions on machine shop turnings. In contrast to this, electric furnace inventories remain quite large, making low phos difficult to move except at 75c. to $1 below OPA ceilings. Short shoveling turnings are hard to dispose of and this grade, when sold, goes at the price of machine shop turnings. However, crushed turnings still sell at the short shoveling turnings price.

105 MM. CASINGS: *These 105 mm. shell casings have been assorted by Italian laborers near the Cassino front and will be reloaded and used again. The Armed services maintain a careful and extensive salvage program, utilizing as much as possible used and damaged equipment and supplies.*

Details of a plan for utilizing 100,000 tons of contaminated, low grade scrap for ship ballast at Pacific shipyards is described in the "West Coast" column, page 84.

With a bad labor situation that is getting worse scrap yards are not hunting for business, knowing they can barely prepare material they now have.

•

BIRMINGHAM—Cast grades are in good demand here at ceiling prices although remote material of this type is not netting shipper full ceiling. Mills are limiting amount of freight they absorb, with amount absorbed varying. There is also considerable demand for blast furnace and open hearth grades. No demand exists here at present for foundry or electric furnace grades of steel and as a result some material normally made into these grades is being prepared for open hearth use.

•

CINCINNATI — Dealers indicate strict adherance to the ceiling prices with virtually no selling under the ceiling prices, although melters refusing to pay springboard differentials tend to increase. Resistance on payment of freight rates on remote material also is reported. Consumers continue to strengthen in their attitude and dealers indicate that a closer check on specifications is being made with threatened rejections frequent.

•

BUFFALO—Allocations of scrap from outside areas continue while the local yield remains at extreme low level. This winter likely will set a record for shipped-in material, most of it going to the district's leading consumer, whose reserve now is estimated as good for only 15 days. Demand for prime scrap remains firm. Electric furnace items are slow. Some dealers are of the opinion heavy battlefield scrap may appear in this district with the opening of Barge Canal navigation. Except for the waiving of premiums on alloys and stainless, ceiling prices prevail.

•

WEST COAST—Standard heavy melting scrap continues available at from $1 to $3 below ceiling. There is practically no market for machine shop turnings and sales when they occur are at 50 per cent of ceiling. Allocated shipments of shipyard plate scrap continue to midwestern buyers who pay a premium for this material. Because of surpluses and depressed markets, sources of ordinary scrap supply outside of the shipyards are tending to dry up and processing and movement are sluggish.

* Baled turnings are $5 per gross ton higher.

BUNDLES: Tin can bundles are $4 below dealers' No. 2 bundles; No. 3 bundles are $2 less than No. 1 heavy melting.

AT NEW YORK CITY or Brooklyn, the maximum shipping point price is $15.33 for No. 1 heavy melting, f.o.b. cars, f.a.s. vessel or loaded on truck. Minimum set at $14 per gross ton at any shipping point in U. S. Other grades carry differentials similar to those in table. New Jersey prices must be computed on basis of all-rail. At Boston the maximum is $15.05 for No. 1 f.o.b. cars, f.a.s. vessel or loaded on trucks. Shipments from a New England shipping point to a consumer outside New England carry maximum transportation charge of $6.66 per ton.

SWITCHING CHARGES: Deductions for shipping points within basing point (cents per gross ton) are: Chicago, 84c.; Pittsburgh, Brackenridge, 55c.; Detroit, 53c.; Midland, Johnstown, Sharon, Youngstown, Warren, Weirton, Cleveland, Toledo, Los Angeles, San Francisco, Pittsburg, 42c.; Seattle, 38c.; Buffalo, Claymont, Harrisburg, 36c.; Atlanta, Birmingham, 32c.; Butler, Monessen, Canton, Steubenville, Cincinnati*, Portsmouth, Ashland, Coatesville, Phoenixville, Bethlehem, Kokomo, Duluth and St. Louis, 28c.; Alabama City, Ala., 26c.; Minnequa, Colo., 22c.; Middletown, 14c.; Conshohocken, Sparrows Point, 11c.

*Basic open hearth and foundry grades, and auto springs and crankshafts, deduct 80c. per ton.

BASING POINT includes switching districts of city named.

Basing point	Switching districts:
Pittsburgh	Bessemer, Homestead, Duquesne, Munhall, McKeesport
Cincinnati	Newport
St. Louis	Granite City, E. St. Louis, Madison, Ill.
Chicago	Gary
Claymont	Chester, Pa.
San Francisco	So. San Francisco, Niles, Oakland

MAXIMUM SHIPPING POINT PRICE: Where shipment is wholly or partially by rail or vessel, or combination of rail and vessel, the scrap is at shipping point when placed f.o.b. railroad or f.a.s. vessel. For motor vehicle shipments scrap is at shipping point when loaded. Then maximum shipping point price shall be: (a) For shipping point located within a basing point, prices shown in above table for scrap at basing point in which shipping point is located, minus applicable switching charge deduction shown in paragraph above labeled "Switching Charges." (b) For shipping points outside basing point, price listed in above table hereof for scrap at most favorable basing point, minus lowest charge for transportation from shipping point to such basing point by rail or water carrier or combination. Where vessel movement is involved, in lieu of established dock charge or any cost customarily incurred at the dock, 75c. per ton must be included as part of deduction in computing shipping point price; 50c. at Memphis; $1 at Great Lakes ports; and $1.25 at New England ports. If no established transportation rate exists for a portion of movement from shipping to basing point, actual charge or cost customarily incurred by shipper in such portion of movement shall be included as part of deduction in computing shipping point price. For exceptions see official order.

UNPREPARED SCRAP: For unprepared scrap, maximum prices shall be $3.50 (and in the case of the material from which No. 1, No. 2, and No. 3 bundles are made $4) less maximum prices for the corresponding prepared scrap. In no case, however, shall electric furnace, acid open hearth and foundry grades be used as the corresponding prepared scrap. A preparation-in-transit charge for unprepared scrap is provided.

NEW LISTED GRADES: Priced in dollars per gross ton less than No. 1 heavy melting steel. Pit scrap, ladle skulls, slag reclaim, etc., of 85% or more Fe priced less $2; 75 to 85% Fe less $4; under 75% Fe less $8 per ton. Mill scale less $8 per ton. Mill cinder and grindings, shipping point maximum price of $4 per gross ton at all U. S. shipping points.

CHEMICAL BORINGS: No. 1 (new, clean, containing not more than 1% oil), $1 less than No. 1 heavy melting; No. 2 (new, clean, containing not more than 1.5% oil), $2 less than No. 1 heavy melting. If loaded in box cars add 75c. mill scale, $8 less than No. 1 heavy melting.

Tool Steel Scrap Prices (MPR 379)

	SEGREGATED Solids Per Lb. Cont. W	SEGREGATED Turnings Per Lb. Cont. W
Type 1. 12% min. W, 1% max. Mo	$1.80	$1.60
Type 2. 5 to 12% W, 1% max. Mo	1.60	1.40
Type 3. 1 to 5% W, 1.5% max. Mo	1.25	1.25
*Type 4. 7% min. Mo, 2% max. W	0.125	0.105
*Type 5. 3.5 to 6% Mo, 4.5 to 6% W	0.135	0.115

UNSEGREGATED SOLIDS

$1.50 per lb. contained W if 5% or more.
$1.15 per lb. contained W if 1 to 5%.
$0.80 per lb. contained Mo if 1.5% or more.

UNSEGREGATED TURNINGS

$1.30 per lb. contained W if 5% or more.
$1.00 per lb. contained W if 1 to 5%.
$0.70 per lb. contained Mo if 1.5% or more.

If both W and Mo are within ranges, payment may be for both W and Mo content.

*Per lb. of scrap material.
If segregated, a premium of $1.50 per lb. of contained Co allowed if Co content is 3% or over. No scrap considered segregated if Co content ranges between 0.5 and 3%.
If Cu or Ni content over 0.25%, price shall be reduced by 50%.
If 500 lb. or less is sold, either segregated or unsegregated, price shall be reduced 2c. per lb. of scrap material.

Revised price schedules, establishing dollars and cents differentials for railroad scrap and establishing revisions in cast iron scrap grades are shown on page 158. These schedules, amendment 14 to RPS No. 4, replace the previous schedules on Railroad Steel Scrap and Cast Iron Scrap sold by railroads.

The various basing points for finished and semi-finished steel are listed in the detailed price tables, pages 153-165.

Composite Prices . . .

Starting with the issue of April 22, 1943, the weighted finished steel price index was revised for the years 1941, 1942 and 1943. See explanation of the change on page 90 of the April 22, 1943, issue.

	FINISHED STEEL	PIG IRON	SCRAP STEEL
March 9, 1944	2.25513c. a Lb.	$23.61 a Gross Ton	$19.17 a Gross Ton

Weighted index based on steel bars, beams, tank plates, wire, rails, black pipe, hot and cold-rolled sheets and strip, representing 78 per cent of the United States output. Index recapitulated in Aug. 28, 1941, issue.

Based on averages for basic iron at Valley furnaces and foundry iron at Chicago, Philadelphia, Buffalo, Valley and Southern iron at Cincinnati.

Based on No. 1 heavy melting steel scrap quotations to consumers at Pittsburgh, Philadelphia and Chicago.

. . . Prices of Finished Iron and Steel

Steel prices shown here are f.o.b. basing points, in cents per lb., unless otherwise indicated. Extras apply. Delivered prices do not reflect 3% tax on freight. (1) Mill run sheet, 10c. per 100 lb. under base; primes 25c. above base. (2) Unassorted 8-lb. coating. (3) Widths up to 12-in. (4) 0.25 carbon and less. (5) Applies to certain width and length limitations. (6) For merchant trade. (7) For straight length material only from producer to consumer. Discount of 25c. per 100 lb. to fabricators. (8) Also shafting. For quantities of 20,000 to 29,999 lb. (9) Carload lot in manufacturing trade. (10) Prices do not apply if rail and water is used. (12) Boxed. (13) Portland and Seattle price, San Francisco 2.50c. (14) This base price to be used in figuring annealed, bright finish wires, commercial spring wire.

EXCEPTIONS TO PRICE SCHED. NO. 6

Slabs—Andrews Steel Co. $41 basing pts.; Wheeling Steel Corp. $34 Portsmouth, Ohio; Empire Sheet & Tin Plate Corp. $41; Phoenix Iron Co. (rerolling) $41, (forging) $47; Granite City Steel Co. $47.50.

Blooms—Phoenix Iron Co. (rerolling) $41, (forging) $47.

Sheet Bar—Empire Sheet & Tin Plate Co. $39 mill; Wheeling Steel Corp. $38 Portsmouth, Ohio.

Billets, Forging—Andrews Steel Co. $50 basing pts.; Follansbee Steel Corp. $49.50 Toronto; Phoenix Iron Co. $47.00 mill.

Billets, Rerolling—Continental Steel Corp. may charge Acme Steel in Chicago switching area $34 plus freight from Kokomo, Ind.; Northwestern Steel & Wire Co. (Lend-Lease) $41 mill; Wheeling Steel Corp. (small) $36 Portsmouth, Ohio; (blooming mill sizes) applicable base, f.o.b. Portsmouth, Ohio; Stanley Works may sell Washburn Wire Co. under allocation at $39 Bridgeport, Conn.; Keystone Steel & Wire Co. may sell Acme Steel Co. at Chicago base, f.o.b. Peoria; Phoenix Iron Co. $41 mill; Continental Steel Corp. (1¾ x 1¾) $39.50, (2 x 2) $40.60 Kokomo, Ind. (these prices include $1 size extra); Keystone Steel & Wire Co. $36.40 Peoria; Connors Steel Co. $50.69 Birmingham; Ford Motor Co. $34 Dearborn, Mich.

Structural Shapes—Phoenix Iron Co. $2.35 basing pts., (export) $2.50 Phoenixville; Knoxville Iron Co. $2.30 basing pts.; Sheffield Steel Corp. $2.55 St. Louis.

Bar Size Shapes—(Angles) W. Ames & Co., 10 tons or over, $3.10 mill.

Rails—Sweet Steel Co. (rail steel) $50 mill; West Virginia Rail Co. (lightweight) on allocation based Huntington, W. Va.; Colorado Fuel & Iron Corp. $45 Pueblo.

Hot Rolled Plate—Granite City Steel Co. $2.65 mill; Knoxville Iron Co. $2.25 basing pts.; Kaiser Co. $3.20 Pacific Ports.

Merchant Bars—Sheffield Steel Corp. $2.75 St. Louis; W. Ames & Co., 10 tons and over, $2.85 mill; Eckels-Nye Steel Corp., $2.50 basing pts. (rail steel) $2.40; Phoenix Iron Co. $2.40 basing pts.; Sweet Steel Co. (rail steel) $2.35 mill; Joslyn Mfg. & Supply Co. $2.35 Chicago; Central Iron & Steel Co. $2.20 basing pts.; Granite City Steel Co. $2.35 Granite City; Calumet Steel Div., Borg Warner Corp. (8 in. mill bars) $2.35 Chicago; Knoxville Iron Co. $2.30 basing pts. Laclede Steel Co., sales to LaSalle Steel granted Chicago base, f.o.b. Madison, Ill.

Reinforcing Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Sweet Steel Co. (rail steel) $2.35 mill; Columbia Steel Co. $2.50 Pacific Ports.

Cold Finished Bars—Keystone Drawn Steel Co. on allocation, Pittsburgh c.f. base plus c/l freight on hot rolled bars Pittsburgh to Spring City, Pa.; New England Drawn Steel Co. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to Massfield, Mass., f.o.b. Massfield; Empire Finished Steel Corp. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to plants f.o.b. plant; Compressed Steel Shafting Co. on allocation outside New England, Buffalo base plus c/l freight Buffalo to Readville, Mass. f.o.b. Readville; Medart Co. in certain areas, Chicago c.f. base plus c/l freight Chicago to St. Louis, f.o.b. St. Louis.

Alloy Bars—Texas Steel Co. for delivery except Texas and Okla. Chicago base, f.o.b. Fort Worth, Tex.; Connors Steel Co. shipped outside Ala., Mississippi, Louisiana, Georgia, Florida, Tenn., Pittsburgh base, f.o.b. Birmingham.

Hot Rolled Strip—Joslyn Mfg. & Supply Co. $2.30 Chicago; Knoxville Iron Co. $2.25 basing pts.

Hot Rolled Sheets—Andrews Steel Co., Middletown base on shipments to Detroit or area; Parkersburg Iron & Steel Co., $2.25 Parkersburg.

Galvanized Sheets—Andrews Steel Co., $3.75 basing pts.; Parkersburg, Iron & Steel Co. $3.85 Parkersburg; Apollo Steel Co. $3.75 basing pts.; Continental Steel Co., Middletown base on Kokomo, Ind., product; Superior Sheet Steel Co., Pittsburgh base except for Lend-Lease.

Pipe and Tubing—South Chester Tube Co. when priced at Pittsburgh, freight to Gulf Coast and Pacific Ports may be charged from Chester, Pa., also to points lying west of Harrisburg, Pa.

Black Sheets—Empire Sheet and Tinplate Co., maximum base price mill is $2.45 per 100 lb., with differentials, transportation charges, etc., provided in RPS. No. 6.

WAREHOUSE PRICES

Delivered metropolitan areas per 100 lb. These are zoned warehouse prices in conformance with latest zoning amendments to OPA Price Schedule 49.

*Recommended for large sections only. Note: The extras shown are in addition to a base price of 2.70c. per 100 lb., on finished products and $54 per gross ton on semi-finished steel major basing points and are in cents per 100 lb. and dollars per gross ton in semi-finished. When acid open-hearth is specified and acceptable add to basic open hearth alloy differential 0.25c. per lb. for bars and bar strip, $5.00 per gross ton for billets, blooms and slabs. The ranges shown above are restricted to sizes 100 sq. in. or less or equivalent cross sectional area 18 in. wide or under with a max. individual piece weight of 7000 lb.

BASE QUANTITIES

Standard unless otherwise keyed on prices.

HOT ROLLED: Sheets, strip, plates, shapes and bars, 400 to 1999 lb.

COLD ROLLED: Sheets, 400 to 1499 lb.; strip, extras on all quantities; bars, 1500 lb. base; NE alloy bars, 1000 to 39,999 lb.

EXCEPTIONS: (1) 150 to 499 lb. (2) 150 to 1499 lb. (3) 400 to 1499 lb. (4) 450 to 1499 lb. (5) 500 to 1499 lb. (6) 0 to 1999 lb. (7) 400 to 1999 lb. (8) 1000 to 1999 lb. (9) 450 to 3749 lb. (10) 400 to 3999 lb. (11) 300 to 4999 lb. (12) 300 to 10,000 lb. (13) 400 to 14,999 lb. (14) 400 lb. and over. (15) 1000 lb. and over. (16) 1500 lb. and over. (17) 2000 lb. and over. (18) 3500 lb. and over.

(a) Philadelphia: Galvanized sheets, 25 or more bundles.

Extra for size, quality, etc., apply on above quotations.

*Add 0.271c. for sizes not rolled in Birmingham.

**City of Philadelphia only. Applicable freight rates must be added to basing point prices to obtain delivered price to other localities in metropolitan area.

CAST IRON WATER PIPE

Per Net Ton

6-in. and larger, del'd Chicago	$54.80
6-in. and larger, del'd New York	52.20
6-in. and larger, Birmingham	46.00
6-in. and larger f.o.b. cars, San Francisco or Los Angeles	69.40
6-in. and larger f.o.b. cars, Seattle	71.20

Class "A" and gas pipe, $3 extra; 4-in. pipe is $3 a ton above 6-in. Prices shown are for lots of less than 200 tons. For 200 tons or over, 6-in. and larger is $45 at Birmingham and $53.80 delivered Chicago, $59.40 at San Francisco and Los Angeles, and $70.20 at Seattle. Delivered prices do not reflect new 3 per cent tax on freight rates.

LAKE SUPERIOR ORES

(51.50% Fe, Natural Content, Delivered Lower Lake Ports)*

Per Gross Ton

Old range, bessemer, 51.50	$4.75
Old range, non-bessemer, 51.50	4.60
Mesaba, bessemer, 51.50	4.60
Mesaba, non-bessemer, 51.50	4.45
High phosphorus, 51.50	4.35

*Adjustments are made to indicate prices based on variance of Fe content of ores as analyzed on a dry basis by independent laboratories.

SEMI-FINISHED STEEL

Ingots, Carbon, Rerolling

Base per gross ton, f.o.b. mill.... $31.00

Exceptions: Phoenix Iron Co. may charge $38.75; Kaiser Co., $43.00 f.o.b Pacific Coast Ports; Empire Sheet & Tinplate Co., $34.25.

Ingots, Carbon, Forging

Base per gross ton, f.o.b. Birmingham, Buffalo, Chicago, Cleveland, Gary, Pittsburgh, Youngstown $36.00

Exceptions: Phoenix Iron Co. may charge $43.00; Empire Sheet & Tinplate Co., $39.25, f.o.b. Mansfield, Ohio; West Coast producers, $48.00, f.o.b. Pacific Coast Ports.

Ingots, Alloy

Base per gross ton, f.o.b. Bethlehem, Buffalo, Canton, Coatesville, Chicago, Massillon, Pittsburgh $45.00

Exceptions: C/L delivered Detroit add $2.00; delivered East Michigan add $3.00. Connors Steel Co. may charge $45.00 f.o.b. Birmingham.

Billets, Blooms and Slabs

Pittsburgh, Chicago, Gary, Cleveland, Youngstown, Buffalo, Birmingham, Sparrows Point (rerolling only). Prices delivered Detroit are $2.00 higher; delivered E. Michigan, $3 higher; f.o.b. Duluth, billets only, $2.00 higher; billets f.o.b. Pacific ports are $12 higher. Delivered prices do not reflect three per cent tax on freight rates.

	Per Gross Ton
Rerolling	$34.00
Forging quality	40.00

For exceptions on semi-finished steel see the footnote on the page of finished steel prices.

Alloy Billets, Blooms, Slabs

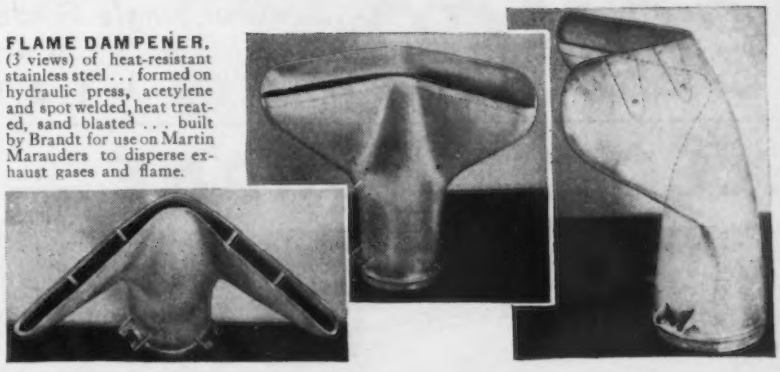
Pittsburgh, Chicago, Canton, Massillon, Buffalo, or Bethlehem, per gross ton 54.00

Price delivered Detroit $2.00 higher; E. Michigan $3.00 higher.

Shell Steel

	Per Gross Ton
3 in. to 12 in.	$52.00
12 in. to 18 in.	54.00
18 in. and over	56.00

Basic open hearth shell steel, f.o.b. Pittsburgh, Chicago, Buffalo, Gary, Cleve-



FLAME DAMPENER, (3 views) of heat-resistant stainless steel . . . formed on hydraulic press, acetylene and spot welded, heat treated, sand blasted . . . built by Brandt for use on Martin Marauders to disperse exhaust gases and flame.

Forming, Welding, Fabricating—

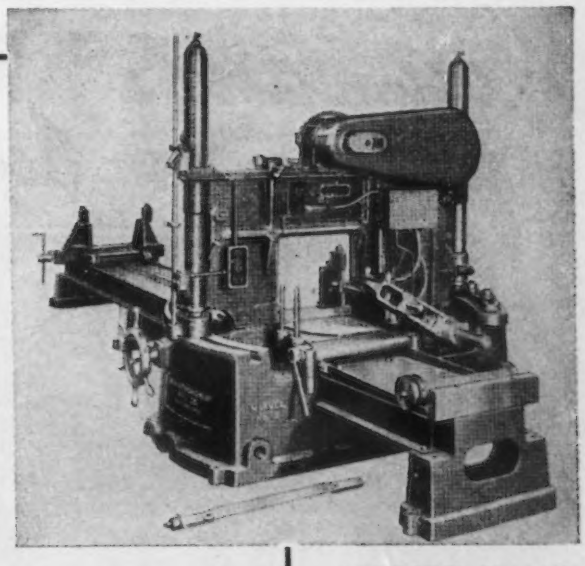
Call BRANDT of Baltimore

for Precision in Heavy Plate and Sheet Steel Work

Here is an 8½ acre plant . . . with the most modern equipment for shearing, rolling, forming, welding and completely fabricating ferrous, non-ferrous and alloy metals to your specifications . . . from the lightest gauge up to and including 1¼" mild steel or ¾" armor plate. Extensive war contracts necessarily limit our present acceptance of new business for immediate delivery. For information, address: Charles T. Brandt, Inc., Baltimore-30, Maryland.

BRANDT of Baltimore—*Craftsmen in Metal Since 1890*

CUTS the Toughest Steels and Largest Sizes *easily.*



This giant hydraulic metal - cutting saw is more than just a larger hack saw. It is a new development in metal-cutting methods that introduces a new principle of metal sawing — the Roll-stroke blade action makes it possible to cut the toughest steels in the largest sizes easily and rapidly. It also permits a simple and efficient, very low pressure Hydraulic Feed System.

Built for heavy work, completely enclosed in heavy housing, this machine will stand up under the rough usage of the average steel mill warehouse and forge shop, where it will speed cutting-off, and reduce material loss.

MARVEL No. 18

Giant Hydraulic Hack Saw

Capacity 18"x18"

Cuts angles up to 45° by simply swiveling upper machine housing.

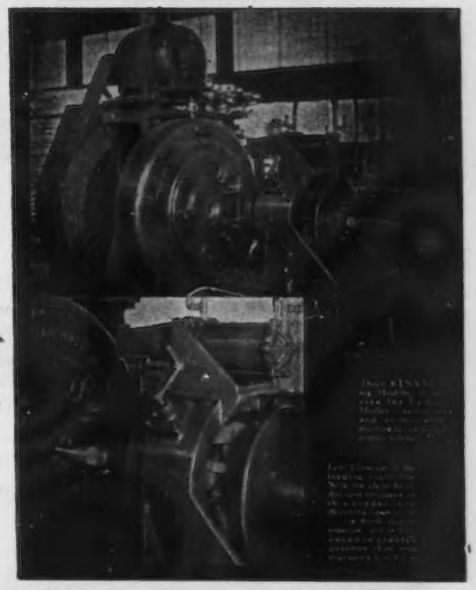
¼ in.	31	12
⅜ to 2 in.	38	19½
Steel (Lap, extra strong, plain ends)		
2 in.	59	48½
2½ and 3 in.	63	52½
3½ to 6 in.	66½	56
Wrought Iron (Same as Above)		
2 in.	33½	15½
2½ to 4 in.	39	22½
4½ to 6 in.	37½	21

On butt weld and lap weld steel pipe jobbers are granted a discount of 5%. On less-than-carload shipments prices are determined by adding 25 and 30% and the carload freight rate to the base card.

F.o.b. Gary prices are two points lower discount or $4 a ton higher than Pittsburgh or Lorain on lap weld and one point lower discount, or $2 a ton higher on all butt weld.

ETNA

A client of ours had a job of pointing heavy-walled copper tubing, and wanted to speed up the operation. Just how to do it didn't appear on the horizon, and so they did the safe and logical thing—they put their swaging job up to Etna.



The answer to that problem is illustrated on this page. It's a modern Etna Swaging Machine that points *more* copper tubes per hour in less time at less cost. If you have a problem involving tapering or reducing tubing and solid rounds—ask Etna about it.

Etna has the swaging machines from ⅜" to 4" and the experience to help you get the most out of this type of machine.

IF IT'S A QUESTION OF TAPERING, SIZING OR REDUCING OF ROUND SOLIDS OR TUBING...
"Ask ETNA About Swaging"

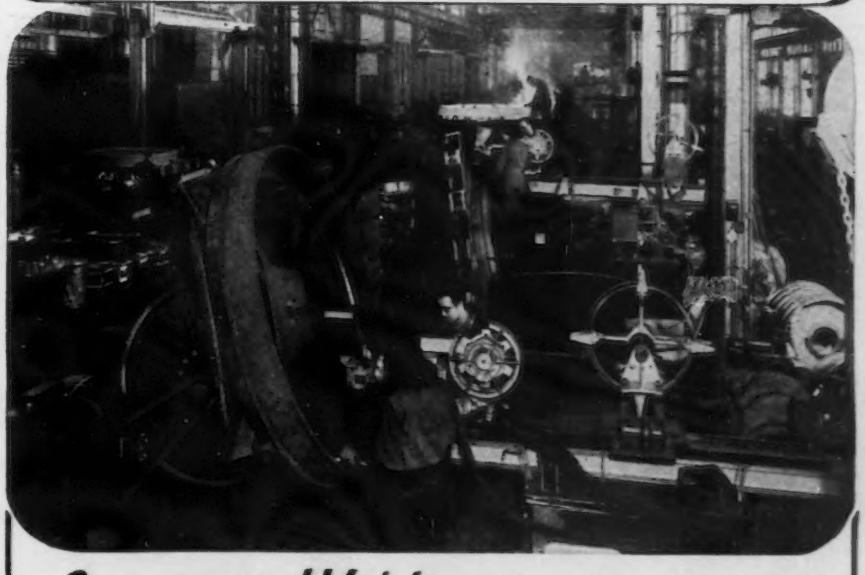
C-F POSITIONERS



Automatic Welding—is possible on many jobs if you have a C-F Welding Positioner. Coming in 6 sizes (capacities to 30,000 lbs.) tables tilt to 135° beyond horizontal and rotate 360°, under push button control. Exclusive C-F Variable-Speed control gives table rotations ranging down to 0 r.p.m. for all sizes.

All C-F Positioners are multi-purpose tools equally efficient on either job or production welding.

GRAY FORGE IRON: Valley or Pittsburgh furnace $23.50

(1) Pittsburgh Coke & Iron Co. (Sharpsville, Pa., furnace only) and the Struthers Iron and Steel Co., Struthers, Ohio, may charge 50c. a ton in excess of basing point prices for No. 2 foundry, basic, bessemer and malleable.

(2) Price shown is for low-phosphorous iron; high-phosphorous sells for $28.50 at the furnace.

(3) E. & G. Brooke Co. permitted to charge $1.00 per ton extra.

(4) Pittsburgh Ferromanganese Co. (Chester furnace only) may charge $2.25 a ton over maximum basing point prices.

Basing point prices are subject to switching charges; silicon differentials (not to exceed 50c. a ton for each 0.25 per cent silicon content in excess of base grade which is 1.75 per cent to 2.25 per cent); phosphorous differentials, a reduction of 38c. per ton for phosphorous content of 0.70 per cent and over; manganese differentials, a charge not to exceed 50c. per ton for each 0.50 per cent manganese content in excess of 1.00 per cent. Effective March 3, 1943, $2 per ton extra may be charged for 0.5 to 0.75 per cent nickel content and $1 per ton extra for each additional 0.25 per cent nickel.

METAL POWDERS

Prices are based on current market prices of ingots plus a fixed figure. For ton lots f.o.b. shipping point, in cents per lb.

Copper, electrolytic, 150 and 200 mesh	21⅛ to 23⅛c.
Copper, reduced, 150 and 200 mesh	20½ to 25½c.
Iron, commercial, 100 and 200 mesh, 96 + % Fe	13½ to 15c.
Iron, crushed, 200 mesh and finer, 90 + % Fe	4c.
Iron, hydrogen reduced, 300 mesh and finer, 98½ + % Fe	63c.
Iron, electrolytic, unannealed, coarser than 300 mesh, 99 + % Fe	30 to 33c.
Iron, electrolytic, annealed minus 100 mesh, 99 + % Fe	42c.
Iron, carbonyl, 300 mesh and finer, 98-99.8 + % Fe	90c.
Aluminum, 100 and 200 mesh	*23 to 27c.
Antimony, 100 mesh	20.6c.
Cadmium, 100 mesh	$1
Chromium, 150 mesh	$1.03
Lead, 100, 200 & 300 mesh, 11½ to 12½c.	
Manganese, 150 mesh	51c.
Nickel, 150 mesh	51½c.
Solder powder, 100 mesh, 8½c. plus metal	
Tin, 100 mesh	58¾c.
Tungsten metal powder, 98%-99%, any quantity, per lb.	$2.60
Molybdenum powder, 99%, in 200-lb. kegs, f.o.b. York, Pa., per lb.	$2.60
Under 100 lb.	$3.00

*Freight allowed east of Mississippi.

Under 2,000 lb. or ft.	65%

Using Hannifin Pneumatic Arbor Presses means easier handling. Even with new help or women operators the work is simple and easy. A touch of the control valve operates the press, with a positive, rapid, smooth action. Fatigue is minimized, and the operator's attention can be devoted to the work. For fast, uniform production, investigate the advantages of Hannifin Pneumatic Presses. Write for Bulletin 48-A.

HEAT-TREATED STEEL SHOT

We manufacture shot and grit for endurance

A shot or grit that will blast fast with a clean finish.

This is the only reason why so many operators are daily changing to our shot and grit, from Maine to California.

The unprecedented demand for our—

Heat-Treated Steel Shot and Heat-Treated Steel Grit

has enabled us to expand our production and maintain a quality that is more than satisfactory to our hundreds of customers all over the country.

"HERCULES" REG. U.S. PAT. OFF. RED-STRAND WIRE ROPE

You Can Depend On "Hercules" (Red Strand) Wire Rope

Highlights of Quality

1. Acid Open-Hearth Steel Wire
2. Rigid Tests and Inspections
3. Correct Manufacturing Methods
4. Furnished in both the Round and Flattened Strand constructions, in either Standard or Preformed Type.

• • Results are what count, and the performance record of this wire rope continues to make and hold friends.

There is no guess work when you use "HERCULES" (Red-Strand) Wire Rope. It is designed and built to do specific jobs better . . . safer . . . more economically. If you will tell us how you use wire rope, we shall be glad to suggest the construction and type most suitable for your conditions.

PRICES

Ferromanganese

78-82% Mn, maximum contract base price per gross ton, lump size, f.o.b. car at Baltimore, Bethlehem, Philadelphia, New York, Birmingham, Rockdale, Rockwood, Tenn.

Carload lots (bulk)	$135.00
Carload lots (packed)	141.00
Less ton lots (packed)	148.50

Premium, $1.70 for each 1% above 82% Mn; penalty, $1.70 for each 1% below 78%.

Manganese Metal

Contract basis, lump size, per lb of metal, f.o.b. shipping point with freight allowed. Spot sales add 2c. per lb.

96-98% Mn, .2% max. C, 1% max. Si, 2% max. Fe.

Carload, bulk	36c.
L.c.l. lots	38c.

95-97% Mn, .2% max. C, 1.5% max. Si, 2.5% max. Fe.

Carload, bulk	34c.
L.c.l. lots	35c.

Spiegeleisen

Maximum base, contract prices, per gross ton, lump, f.o.b. Palmerton, Pa.

	16-19% Mn 3% max. Si	19-21% Mn 3% max. Si
Carloads	$35.00	$36.00
Less ton	47.50	48.50

Electric Ferrosilicon

OPA maximum base price cents per lb. contained Si, lump size in carlots, f.o.b. shipping point with freight allowed to destination.

	Eastern Zone	Central Zone	Western Zone
50% Si	6.65c.	7.10c.	7.25c.
75% Si	8.05c.	8.20c.	8.75c.
80-90% Si	8.90c.	9.05c.	9.55c.
90-95% Si	11.05c.	11.20c.	11.65c.

Spot sales add: 45c. per lb. for 50% Si, .3c. per lb. for 75% Si, .25c. per lb. for 80-90% and 90-95% Si.

Silvery Iron

(Per Gross Ton, base 6.00 to 6.50 Si)

F.o.b. Jackson, Ohio	$29.50*
Buffalo	30.75*

For each additional 0.50% silicon add $1 a ton. For each 0.50% manganese over 1% add 50c. a ton. Add $1 a ton for 0.75% phosphorous or over.

*OPA price established 6-24-41.

Bessemer Ferrosilicon

Prices are $1 a ton above silvery iron quotations of comparable analysis.

Silicon Metal

OPA maximum base price per lb. of contained Si, lump size, f.o.b. shipping point with freight allowed to destination, for l.c.l. above 2000 lb., packed. Add .25c. for spot sales.

	Eastern Zone	Central Zone	Western Zone
96% Si, 2% Fe.	13.10c.	13.55c.	16.50c.
97% Si, 1% Fe.	13.45c.	13.90c.	16.80c.

Ferrosilicon Briquets

OPA maximum base price per lb. of briquet, bulk, f.o.b. shipping point with freight allowed to destination. Approximately 40% Si. Add .25c. for spot sales.

	Eastern Zone	Central Zone	Western Zone
Carload, bulk	3.35c.	3.50c.	3.65c.
2000 lb.-carload	3.8c.	4.2c.	4.25c.

Silicomanganese

Contract basis lump size, per lb. of metal, f.o.b. shipping point with freight allowed. Add .25c. for spot sales. 65-70% Mn, 17-20% Si, 1.5% max. C.

Carload, bulk	6.05c.
2000 lb. to carload	6.70c.
Under 2000 lb.	6.90c.
Briquets, contract, basis carlots, bulk freight allowed, per lb.	5.80c.
2000 lb. to carload	6.30c.
Less ton lots	6.55c.

Ferrochrome

(65-72% Cr, 2% max. Si)

OPA maximum base contract prices per lb. of contained Cr, lump size in carload lots, f.o.b. shipping point, freight allowed to destination. Add .25c. per lb. contained Cr for spot sales.

	Eastern Zone	Central Zone	Western Zone
0.06% C	23.00c.	23.40c.	24.00c.

Other Ferroalloys

Ferrotungsten, Standard grade, lump or ¼X down, packed, f.o.b. plant at Niagara Falls, New York, Washington, Pa., York, Pa., per lb. contained tungsten. 10,000 lb. of more... $1.90

Ferrovanadium, 50-55%, contract basis, f.o.b. producer's plant, usual freight allowances, per lb. contained Va.
- Open Hearth $2.70
- Crucible $2.80
- Primos $2.90

Cobalt, 97% min., keg packed, contract basis, f.o.b. producer's plant, usual freight allowances, per lb. of cobalt metal $1.50

Vanadium pentoxide, 88%-92% V_2O_5 technical grade, contract basis, any quantity, per lb. contained V_2O_5. Spot sales add 5c. per lb. contained V_2O_5 ..... $1.10

Ferroboron, contract basis, 17.50% min. Bo, f.o.b. producer's plant with usual freight allowances, per lb. of alloy.
- 2000 lb. to carload $1.20
- Under 2000 lb. 1.30
- Per lb. alloy $1.20
- Ton lots $1.25

Silcaz No. 3, contract basis, f.o.b. producer's plant with usual freight allowances, per lb. of alloy. (Pending OPA approval)
- Carload lots ..... 25c.
- 2000 lb. to carload ..... 26c.

Silvaz No. 3, contract basis, f.o.b. producer's plant with freight allowances, per lb. of alloy (Pending OPA approval)
- Carload lots ..... 58c.
- 2000 lb. to carload ..... 59c.

Grainal No. 1, f.o.b. Bridgeville, Pa., freight allowed 50 lb. and over, max. based on rate to St. Louis, per lb. ..... 87.5c.

Bortram, f.o.b. Niagara Falls
- Ton lots, per lb. ..... 45c.
- Less ton lots, per lb. ..... 50c.

Ferrocolumbium, 50-60%, contract basis, f.o.b. plant with freight allowances, per lb contained Cb.
- 2000 lb. lots $2.25
- Under 2000 lb. lots $2.30

Ferrotitanium, 40%-45%, f.o.b. Niagara Falls, N. Y., ton lots, per lb. contained titanium ... $1.23
- Less ton lots $1.25

Ferrotitanium, 20%-25%, 0.10 C max., ton lots, per lb. contained titanium $1.35
- Less ton lots $1.40

High-carbon ferrotitanium, 15%-20%, 6%-8% carbon, contract basis, f.o.b. Niagara Falls, N. Y., freight allowed East of Mississippi River, North of Baltimore and St. Louis, per carload $142.50

Ferrophosphorus, 18% electric or blast furnace, f.o.b. Anniston, Ala., carlots, with $3 unitage freight equaled with Rockdale, Tenn., per gross ton $58.50

Ferrophosphorus, electrolytic 23-26%, carlots, f.o.b. Monsanto (Siglo), Tenn., $3 unitage freight equalized with Nashville, per gross ton $75.00

Ferromolybdenum, 55-75%, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained molybdenum ..... 95c.

Calcium molybdate, 40%-45%, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained Mo ..... 80c.

Molybdenum oxide briquettes, 48%-52% Mo, f.o.b. Langeloth, Pa., per lb. contained Mo ..... 80c.

Molybdenum oxide, in cans, f.o.b. Langeloth and Washington, Pa., per lb. contained Mo ..... 80c.

Zirconium, 35-40%, contract basis, f.o.b. producer's plant with freight allowances, per lb. of alloy. Add ¼c. for spot sales
- Carload lots ..... 14c.

Zirconium, 12-15%, contract basis, lump, f.o.b. plant with usual freight allowances, per lb. of alloy
- Carload, bulk ..... 4.6c.

Alsifer (approx. 20% Al, 40% Si and 40% Fe), contract basis, f.o.b. Niagara Falls, carload, bulk ..... 6.5c.
- Ton lots ..... 7.25c.

Simanal (approx. 20% Si, 20% Mn, 20% Al), contract basis, f.o.b. Philo, Ohio, with freight not to exceed St. Louis rate allowed, per lb.
- Car lots ..... 8.75c.
- Ton lots ..... 9.25c.

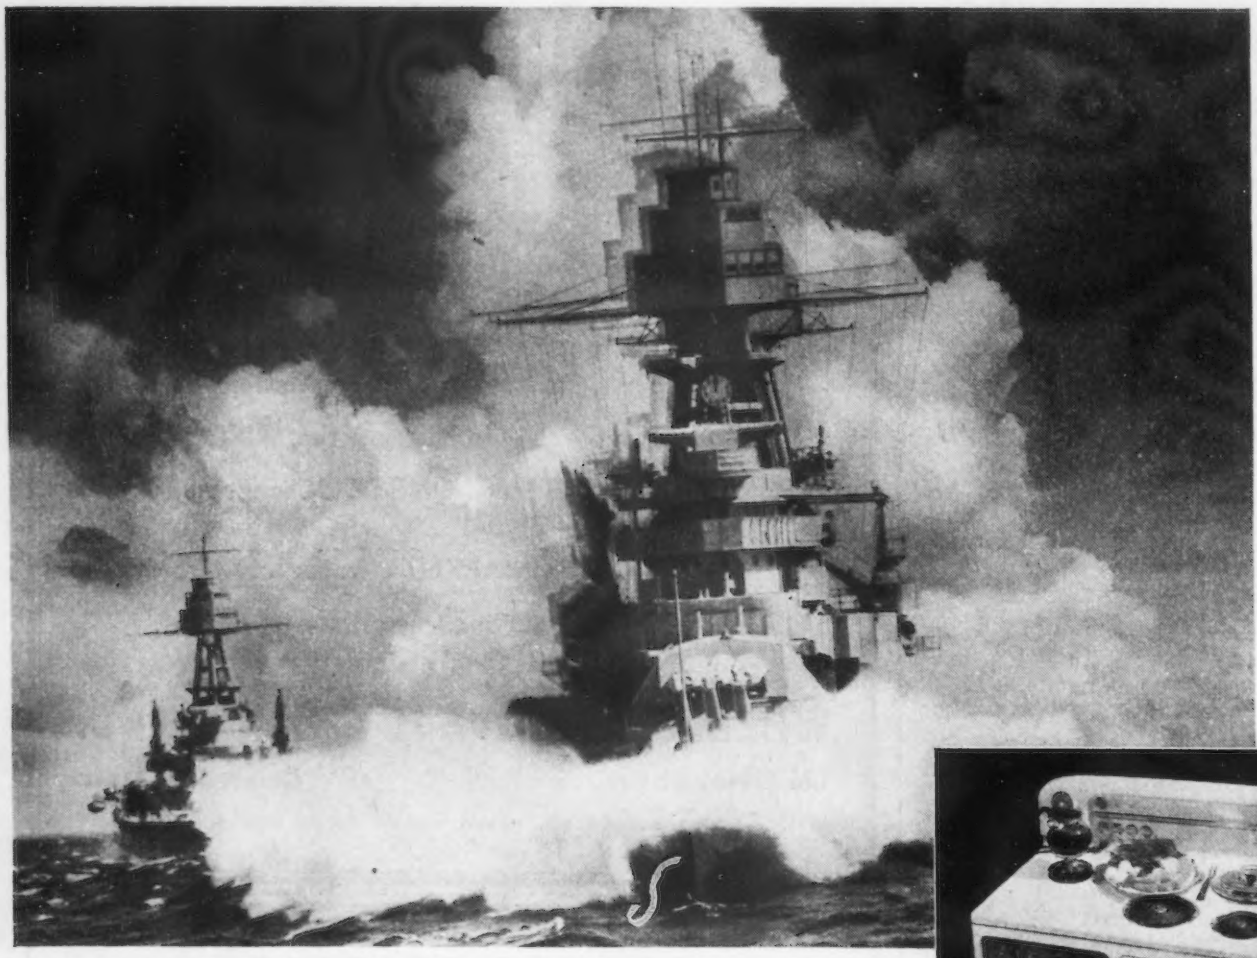
Making strong the things that make America strong



Holding a Ship's Shape... Shaping a Stove's Course

THAT SHIP . . . defying a rough-and-tumble fighting ocean . . . needs stiff-willed stamina in the bolts and nuts that secure its ribs.

That stove . . . built on a fast-moving production schedule . . . needs bolts and nuts that are quick on the get-away and take tightening without fumbling or jamming.

For fastening strength that will resist whatever beating a ship or steam-shovel or stone-crusher can give . . . for accurate mating that hurries a product along an assembly line: fasten with RB&W bolts and nuts.

RB&W developments in cold-forming and cold-punching have set new standards in holding power, accuracy and appearance for all kinds of fastening devices.

The dependability you would expect from the accumulated experience of 99 years and the results of hundreds of thousands of dollars' worth of research work . . . is wrapped up with every shipment of RB&W products. Little wonder that so much of the best-known farm machinery, transportation equipment, electrical appliances, construction equipment and furniture is put together faster and held together better by RB&W fasteners.

Profit Not Without Honor

YOU remember the saying: "A prophet is not without honor save in his own country." It was originated in the days when a prophet had a hard time making both ends meet or even in getting his neighbors to listen to him. Maybe there had been some overdoing of the art in those days, or a little shady practice by a minority of the prophets which resulted in giving the profession a black eye. It has gotten well over that now and the practitioners of prophecy are doing nicely today, judging by the size of their circulation lists and the prices they charge for their services.

Profits apparently are undergoing a period of public censuring somewhat similar to the lambasting that the prophets took in the days of old. Perhaps it is war psychology and the fact that people do not like the idea of money being made out of suffering that have started people looking askance at profit statements in general. At any rate it has gone beyond the mere war conception and there seems to be a notion that large profits are immoral or at least unethical, at any time.

If this notion carries over into our postwar thinking it will do considerable harm, because what we will need then, for industries to grow in employment and wages and for the National debt to diminish will be more and better profits. The only unprofitable business that I know of that can grow and expand and enlarge its payrolls in spite of red ink is government. And that can only be done by taxing profitable businesses.

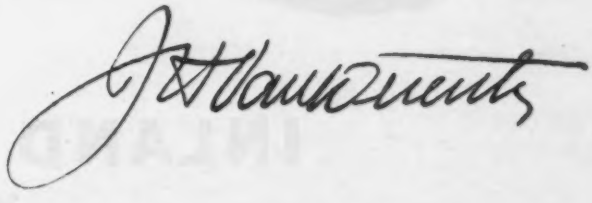
Profits are immoral and unethical only when not earned. Those kind we can eliminate through proper legislation.

The businesses that are the best profit earners are going to be the ones that will put and keep us on our feet after the war. The richest earth gives the best crops. Thistles thrive on stony ground.

Take three typical producers in any industry. One, a submarginal company that just manages to keep its head above water. Another, an average company that earns an average profit over a ten-year period of say six or eight cents per dollar of volume. And still another, an exceptionally efficient and well managed company making the same product but averaging twice that profit. In which of these companies would you expect to find the best wages, the best working conditions and the most promising prospect for growth?

Earned profits should not be without honor in our own country. Millions of profitable private enterprises will do more to keep us free of fascism or any other 'ism than any other factor.

Tax our profits from enterprise as much as necessary, after they are made. But encourage the making of them for therein lies strength and health for both people and government.



INLAND ENGINEERS
Finish Another Wartime Job

Up the channel from the Inland plant, at the lower end of Lake Michigan, stand two new blast furnaces, and two batteries of coke ovens —built by Inland engineers for the Government—to increase the supply of pig iron for the nation at war.

This is only one of the many wartime jobs Inland engineers have undertaken and carried through to completion in fast time. For instance there is the Inland No. 6 blast furnace—put in operation over a year ago—one year after the foundation piling was driven. And the new electrolytic tin plate unit—a project that saves critical tin—reduces by one-half the amount used for plating.

Inland engineers, known for their drive and foresight through the years, apply their skill to the needs of war—and look for new opportunities to serve a victorious America.

The IRON AGE
MARCH 16, 1944

NEWS FRONT

► If the German war ends before Japan is knocked out, Edwin C. Barringer of the Institute of Scrap Iron and Steel foresees a cut of 33 to 50 per cent in war material production.

All land fighting will not cease then, however, and contracts will be terminated in better fashion.

If government price controls are relaxed in the immediate postwar period, he says price fluctuations may be terrifying.

► First transaction under new setup for surplus war property disposal is the sale of the San Jacinto shipyard at Houston by the Maritime Commission to Dupont. Plant will be adapted for the preparation of phenothiazine.

► The Truman Committee still supports the postwar bond proposal which provides for the setting aside of reserves up to 20 per cent of the normal net income tax to be invested in a special issue of non-negotiable, non-interest-bearing government bonds. These bonds redeemable 18 months after the war would provide the Treasury with immediate funds and the taxpayer with means for reconversion.

► American Brake Shoe Co.'s new experimental foundry can handle castings weighing 2000 lb. Immediate work will be devoted to pilot centrifugal and static castings practices for the aircraft industry and experimental work assigned by the War Metallurgy Committee.

► Curtailed for a while, the landing mat program is being resumed.

► Under pressure to supply operational aircraft for the defense of Germany, the development of new designs in Germany has lagged considerably.

The most interesting new fighter is the Focke-Wulf Fw 290, which has abandoned the BMW 801 motor in favor of the 2000 plus hp. Junkers Jumo 213. This fighter is the first operational type of the Luftwaffe made entirely of wood, guaranteeing a considerable speed-up in production.

Another new fighter is the Me 209, and it also may be built of wood, or some German reports have hinted that the construction will be of plastics. This new plane may be more heavily armored than the 109 series, perhaps replacing the 20 mm. cannon with a 30 mm. calibre.

► Junkers, Arado, Heinkel and Messerschmitt have all done a great deal of developmental work on stratosphere bombers, but indications are that this type of craft has not reached front-line perfection, other than a few prototypes employed for reconnaissance purposes.

There have been many German patents on jet propulsion over the past five years, and Messerschmitt, Heinkel, Arado and Henschel have all studied this development assiduously. However, all indications are that German jet propelled planes will fly into combat until only long after Allied jet planes are in operational use.

► In view of the need for stainless steel in civilian goods, the WPB has allocated some 2000 tons per month for first quarter to OCS. Of this amount, about 900 tons per month may go into flat ware.

► WPB's Iron and Steel Scrap Advisory Committee assails claims of carbon steel scrap sufficiency. Specialties, however, are being sold under ceilings.

► Work undertaken in the laboratories of the Timken Roller Bearing Co. on various steel grades indicates the existence of a definite relationship between hot twisting characteristics and forging temperature.

The hot twist test reveals the temperature which must not be exceeded during forging, changes in ductility with varying temperatures and the change with temperature of the force required to deform the steel.

► The new alloy Galv-Weld has been successfully used to regalvanize bare spots caused by welding.

The low melting alloy is rubbed over the heated bare spots to form a smooth coating of the metal which has all of the corrosion resisting properties as well as the wearing qualities of the original galvanized coating.

The new layer is continuous with no holes or fissures.

Evaluating Steel Forgeability

. . . Data obtained from the hot twist test have been a valuable guide in determining the optimum conditions for hot forming operations. The apparatus and procedures used in this test are herein described and the results of tests on various steels interpreted.

o o o

By C. L. CLARK
Research Metallurgical Engineer,
Timken Roller Bearing Co.,
Canton, Ohio

o o o

WHILE considerable attention has been given to the high temperature properties of steels during the past several years, most of this work has been confined to the required operating temperatures and pressures of certain types of equipment; that is, up to temperatures of about 1500 deg. F. Data are meager on the properties of steels at the more elevated temperatures, and yet information of this type is of considerable value in establishing the proper conditions for various hot forming operations like forging.

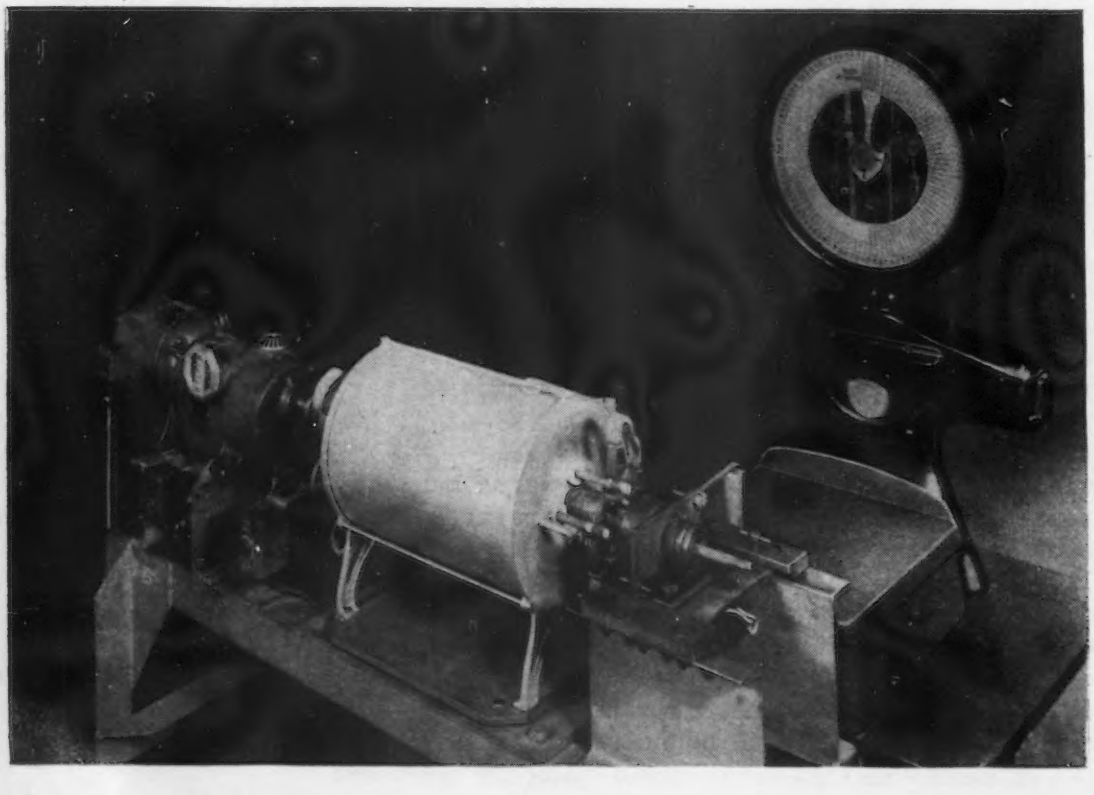
Various tests have been used in the past for determining the proper forging temperatures with varying degrees of success. However, work undertaken in the laboratories of the Timken Roller Bearing Co. indicates that a definite relationship exists between hot twisting characteristics and forging temperature. This test is believed to be more sensitive and the results more quantitative than those obtained from other methods of evaluation.

The hot twist test itself is not new. It was described by Professor Sauveur in his 1939 Campbell Memorial Lecture* in which results were given for several steels, but at temperatures up to 2000 deg. F. only. It has likewise been used by other investigators for determining certain hot working characteristics of steels up to 2500 deg. F.†

* *"Metals at Elevated Temperatures," Transactions, ASST, Vol. 17, pp. 410-448, 1930.*

† *"The New House of Science," Globe Steel Tubes Co., Milwaukee.*

The apparatus used in the Timken Roller Bearing laboratories for determining the hot twist characteristics is shown in Fig. 1. It consists essentially of a furnace for heating and maintaining the specimen at the



o o o

FIG. 1—Hot twist testing apparatus consists of a furnace, a variable speed motor, a chuck mounted in a bearing and a platform scale for measuring the force produced during twisting. The scale reading times the length of the lever arm gives the torque in in.-lb.

o o o

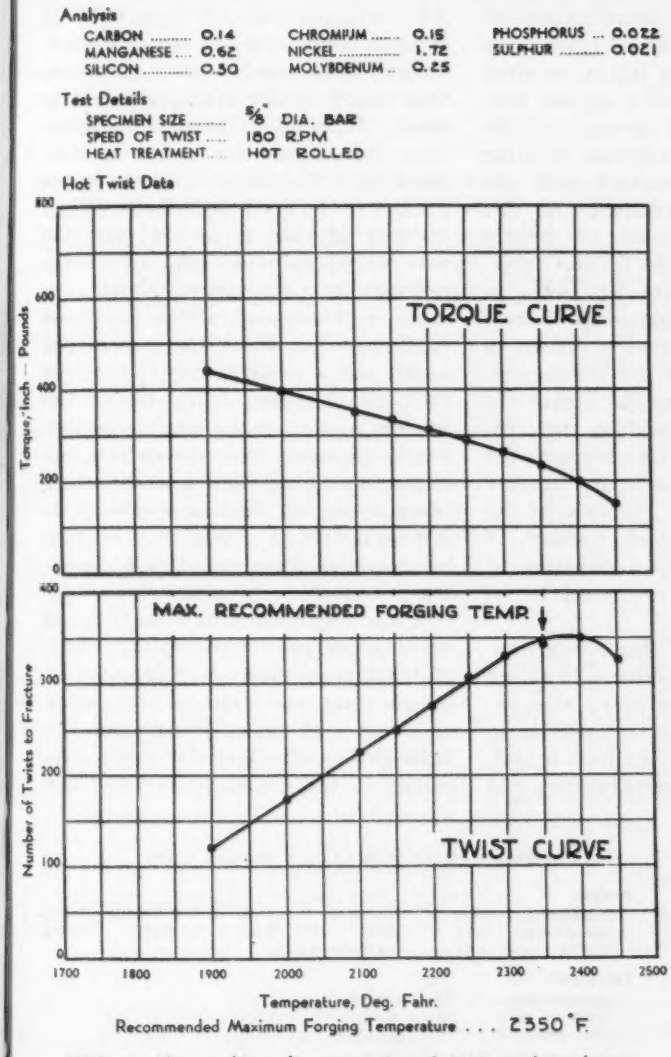


FIG. 2—Hot working characteristics of 4615 steel as determined by the hot twist test.

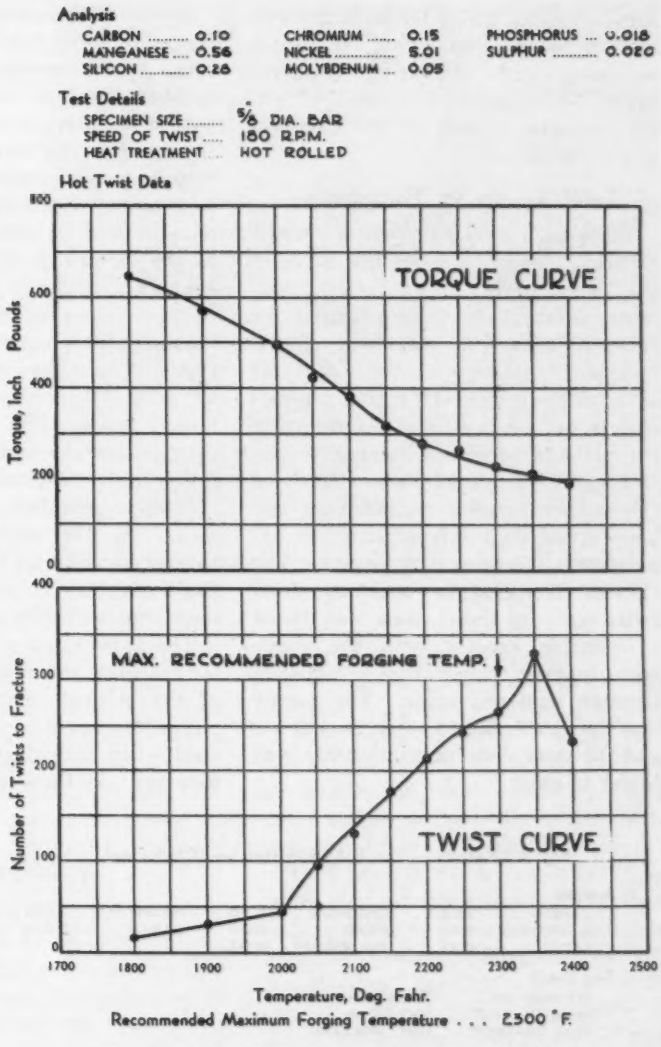

Fig. 3—Hot working characteristics of 2512 steel.

given temperature, a variable speed motor for turning the specimen at the desired rate, a chuck mounted in a bearing to which the torque arm is attached, and a platform scales for measuring the force produced during the twisting of the specimen.

In performing the test, the specimen is placed in the apparatus and fastened in the chuck of the variable speed motor. The specimen is rotated at slow speed while it is being heated to and held at the desired temperature and, after 15 min. at temperature, the motor is stopped, the other chuck tightened and the motor restarted at the desired rate of speed. A counter, which automatically starts and stops at the beginning and end of the test, gives the number of revolutions while the force exerted on the scale is read and recorded. The scale reading, multiplied by the length of the lever arm, gives the torque, expressed in in.-lb.

Work has been done on different specimen sizes, with the steel in varying conditions of initial heat treatment, and at various rates of twist. For convenience, however, the specimen size has been standardized at $\frac{5}{8}$ in. round with the material in the hot rolled condition since at temperatures of 1800 to 2500 deg. F. the initial heat treatment has little if any influence on the results obtained. Likewise for forging applications a rate of twist of 180 rev. per min. is used, which is the lowest operating speed of the motor.

Results obtained from four different steels, two of which are of the constructional type, one a tool steel and the other a stainless grade are given in Figs. 2 to 5.

In each case the number of twists required for fracture increases as the temperature is raised until a critical temperature is reached after which the number of twists decreases. There are, however, differences between the steels in (a) the number of twists required for fracture at a given temperature; (b) the rate at which the number of required twists increases with temperature; (c) the temperature at which the number of twists reaches a maximum, and (d) the rate of decrease in the number of required twists after the critical temperature is passed.

Insofar as the two constructional steels are concerned, not only does 4615 have its temperature of maximum twist 50 deg. F. above that of 2512 but it approaches and departs from this temperature at a much slower rate. The tool steel, 10105, is quite similar to 2512 except that its temperature of maximum twist is considerably lower, being 2150 deg. F. as compared to 2350 deg. F. On the other hand, the stainless 18-8 alloy does not reach its temperature of maximum twist at 2450 deg. F. This steel, however, requires fewer twists for fracture than the other steels, except at the highest temperatures.

The torque curves show the strength to decrease continuously as the temperature is increased and thus the relationship is different from that found in the twist curves. With the different steels, however, there are differences in the magnitude of the

torque at any given temperature and also in the rate at which the torque decreases with increasing temperatures. The stainless 18-8 has the highest strength at each of the temperatures considered.

Twist Results vs. Forgeability

Since each steel possesses a definite critical temperature, on the basis of the twist curves, at which the maximum number of twists required for fracture occurs, it was believed advisable to attempt to correlate this with well established forging temperatures on alloy steels. Considerable trouble had been encountered earlier in forging certain of these steels and the proper forging temperature had been established only after much experimentation on actual forgings. The critical temperature obtained from twist tests on these steels was found to coincide exactly with the maximum forging temperature established through trial and error. The survey was then extended to other type steels and the same definite relationship was found to exist.

A metallographic examination of fractured twist specimens reveals the cause of the decrease in the required number of twists after a certain temperature is reached as well as the reason for the correlation existing between this temperature and the forgeability characteristics. As this temperature is exceeded, the nature of the failure changes in that intergranular cracking appears, even in sections removed from the actual fracture. This condition is shown in Fig. 6. The degree of this intergranular cracking increases the higher the testing temperature is above the critical temperature and this accounts for the resulting decrease in the number of twists. Similarly, the rate of decrease in the required number of twists is undoubtedly a function of the susceptibility of the steel to intergranular cracking.

The appearance of this intergranular cracking at temperatures in excess of the critical temperature also explains the cause of certain defects in steel when forged at too high a temperature. At these temperatures, and for the given rate of application of stress, the strength of the grain boundaries is decreased to such an extent that intergranular cracking is apt to occur. Burning of the steel has often been considered the cause of this cracking, even though oxides are not present in the grain boundaries. While burning of steel is possible and the path of fracture in such cases is intergranular, distinction should be made between steel which has been burnt and that which has been forged at too high a temperature. In the first case, the damage occurs during the heating cycle and the steel is permanently damaged while the defects due to forging at too high a temperature occur during the forging operation itself although of course the heating has established the condition for making those defects possible.

It has long been recognized that the deformation characteristics and path of fracture in steels is a function of temperature and rate of application of stress. At room temperature the deformation of all steels occurs primarily in the grains proper and the

Fig. 4—Results of the hot twist test on 10105 steel.

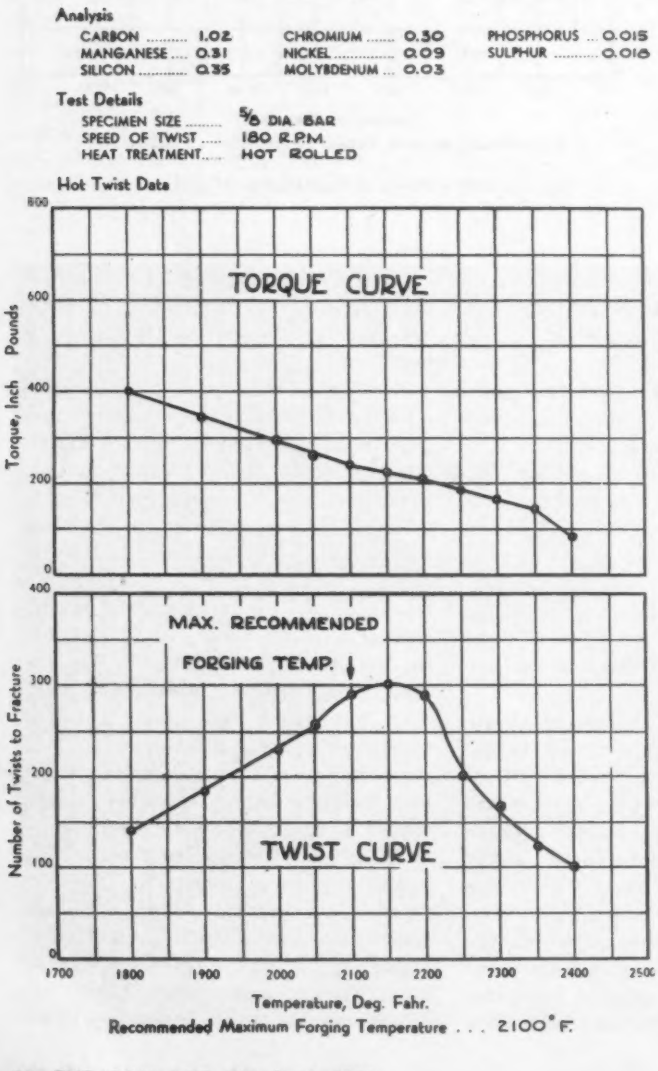

Fig. 5—Results of hot twist on 18-8 stainless steel.

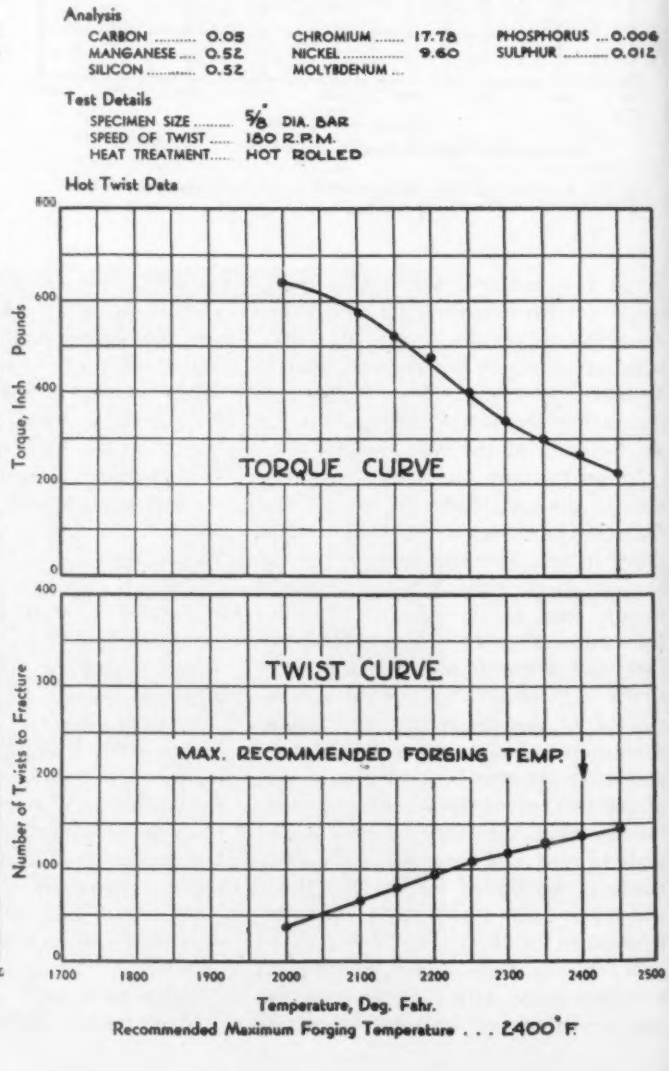

path of fracture is transcrystalline. On the other hand at 1000 deg. F. and under very slow rates of deformation, such as occur in creep or prolonged stress-rupture tests, the path of fracture in the low alloyed steels under simple tension is largely intergranular.

Since rate of deformation is a deciding factor it is not surprising that the temperature required for this change from transcrystalline to intercrystalline failures in the twist test is of the magnitude observed. Moreover, the rates of deformation encountered in forging are similar to those of the twist test and this undoubtedly accounts for the close relationship which has been found to exist between the two. It also explains the reason why tensile tests conducted at these higher temperatures have never been overly useful in evaluating the forgeability of different steels.

o o o

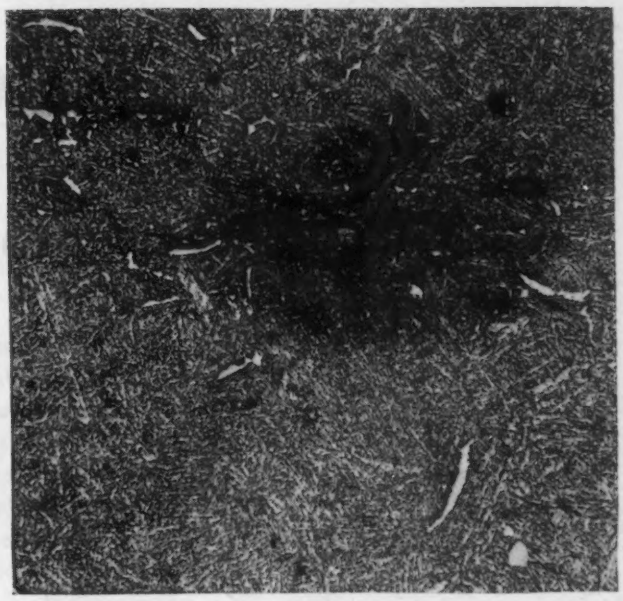

FIG. 6—Exceeding temperatures of maximum twist causes intergranular cracking. (100 diameters.)

o o o

While deformation rate itself is an important factor it seems to lose its effect after a certain rate has been exceeded. For example tests conducted on certain steels under rates of twist varying from 180 to 600 rev. per min. showed the temperature of maximum twist to be nearly constant for a given steel. The speed did, however, have an influence on the total number of twists required for fracture.

It might at first appear strange that correlations should exist between a torsion test, such as the twist test, and forging operations. However, in all forging operations the applied stresses, when they are distributed throughout the steel, are not simple tension or compression, and since metals are weaker in shear than in either tension or compression, it is probably the shearing stresses which are of the greatest importance. This again helps to explain the close relationship which has been found to exist.

Conclusions

Results obtained from the hot twist tests are believed to be of great usefulness in evaluating the forgeability of steels for the test is quantitative in nature and is sufficiently sensitive to reveal:

(1) The temperature which must not be exceeded in the forging operation.

(2) The change in ductility of the steel with varying temperatures.

(3) The change with temperature of the force required to deform the steel. A knowledge of each of these factors should be of assistance in forging all grades of steels and especially those newer analyses on which little past experience is available.

As a matter of precaution and to allow for temperature differentials and possible variation from heat to heat, it is believed advisable to hold the maximum forging temperature 50 deg. F. below the temperature at which the greatest twist results. This precaution is further advisable since it is believed that if the temperature of maximum twist is exceeded the quality of the forging will be affected detrimentally.

Oxygen and Water Vapor in Furnace Gases

OXYGEN present in heat treating atmospheres for steels robs the surface and sometimes even the interior of the steel of carbon. This ruins the surface finish and softens the steel. Water vapor at these temperatures also has a bad effect since it decomposes into hydrogen and oxygen. Water vapor, under such conditions, also appears to act as a catalyst in aiding decarburization.

Presence of unwanted oxygen and water vapor in heat treating atmospheres is detected by passing the gas over a cool surface and by noting the temperature at which condensation occurs. This temperature of condensation varies between —40 and —70 deg. C., depending upon the requirements of the process. Even skilled operators differ in their estimates of dew-point temperature, especially when it is of the order of —40 deg. C. or lower. Furthermore, the process is not continuous and requires the operator to take periodic samples of gas to make the test.

An experimental device developed by Westinghouse utilizes electrons to do the detecting. The electrons furnish a continuous report of their findings to the operator. Oxygen and water vapor is ionized by electron bombardment, whereas constituents of furnace gases are not. The arrangement draws a sample of the gas mixture past an electron gun. As long as the gas is free of impurities, the electron current is constant. However, when oxygen or water vapor are mixed with the gas, some of the electrons are utilized in forming negative ions. This causes a measurable decrease in electron current. Most electron tubes are vacuum devices and the tube employed here is essentially a diode tube which operates with both ends open. The electron emitter and the plate continually operate in a stream of hot furnace gases.

This electronic dew-point indicator removes the difficulty of judging visually determined dew points, a method subject to considerable variation. Furthermore, it provides a continuous indication of gas quality. At present the new development is strictly a laboratory instrument and is not commercially available. Applications of the dew-point indicator will probably be restricted to certain types of furnace gases.

Milling Steel

With Carbide Tipped Cutters

. . . The author compares fly milling with the action of a single point tool taking an interrupted facing cut in a lathe and shows why negative axial rake angles are desirable for maximum cutter life. An exhaustive analysis of all the cutter angles is given, using accepted nomenclature which differs somewhat from that given in the paper originally presented by Mr. Lucht before the annual meeting of the American Society of Mechanical Engineers last December. The author concludes with a tabulation of machine and fixture requirements. The reader is also referred to the article "High Speed Milling in the Aircraft Industry," The Iron Age, Oct. 14, 1943, for other data on the same subject.

o o o

By FRED W. LUCHT
Development Engineer,
Carboloy Co., Inc., Detroit

o o o

ONE of the main reasons for the long delay in the successful application of cemented carbides to the milling of steel has been primarily due to the fact that it was applied in exactly the same manner as it was applied to high speed steel cutters in the past. It has since been found that rigidity of setup, power, the proper cutting speed and the proper tooth loading are of even greater importance than with high speed steel cutters. It was also found that the positive cutting angles used for high speed steel cutters in milling steel were detrimental with cemented carbides and little progress was made until it was learned how to properly apply cemented carbides to single point tools for taking interrupted cuts in turning, facing and boring. This resulted in the use of the proper combination of positive and negative cutting angles and gave the first real clue to the successful application of cemented carbides to milling steel because all milling cuts basically are interrupted cuts.

An analogy will be illustrated to show how lathe tool design can be translated into milling cutter design. Fig. 1 shows a piece of work mounted in the chuck of an engine lathe, with the tool, taking an interrupted facing cut as shown in section BB. Note that the tool has a negative back rake angle which prevents it from digging into the work endwise as it is fed outward. When the work hits the tool, this negative back rake allows the initial impact load to be taken back from the nose of the tool where the tool has its greatest strength. This type of setup tends toward maximum tool life.

For comparison, in Fig. 2 a part of the same cross-section as in section BB, Fig. 1, is mounted on the cross slide of the lathe and a cutter body holding the same single point tool is mounted in the chuck jaws of the lathe. When the work is fed into the tool an improvised type of fly face milling cutter is obtained. In Fig. 3 the analogy is carried one step further. In this case the part is clamped to the table of a milling machine and the same single point tool as was shown in Figs. 1 and 2 is clamped in a face milling cutter body. It can be seen that this cemented carbide tipped milling cutter in its simplified form incorporates the same basic features as outlined in the facing operation on the engine lathe.

Angles Control Tool Life

On all cutting tools the proper combination of the side cutting edge angle (bevel angle on milling cutters), the back rake angle (axial rake angle on milling cutters) and the side rake angle (radial rake angle on milling cutters) has a direct bearing on tool life since these three angles control the amount of protection afforded the cutting edge and the nose radius or chamfer. The latter is usually the weakest portion of any cemented carbide cutting tool and must receive maximum protection. It is doubly important to protect the nose radius because it also maintains the size on the cut.

The radial rake angle (see Fig. 4) is the angle which the cutting face of each blade makes with a radial line passing through the cutting edge. In cutting steel, rake angles between 8 deg. positive and 10 deg. negative are being employed at the present time, depending upon the nature of the application. Where the cutters mill past the work and bevel angles can be used, for example, a positive rake is advantageous for soft steels and a negative rake for hard steels. Experience dictates use of about 8 deg. positive rake for steels below 200 Brinell hardness, gradually reducing the rake to 5 deg. negative for steels in the 325 to 500 Brinell hardness range. For operations involving milling to a square or almost square shoulder a negative rake of 3 to 7 deg. should be used to assure maximum strength at the cutting edge even at a sacrifice of cutter efficiency.

It should be kept in mind that rake angles in the positive direction result in minimum power consumption and permit the use of deeper cuts and heavier feeds than negative rake angles. Only when really necessary should negative rake angles be used to strengthen the cutting edge since

their use results in a corresponding sacrifice in metal removing efficiency.

Negative Axial Rake

It has been seen that in facing or turning steel with an interrupted cut with a single point tool, a negative back rake angle is used to permit the impact load to be taken some distance back from the edge. By the same token, when milling steel the cutting face of the teeth on milling cutters should be set at a negative axial rake angle to protect the nose radius or chamfer by allowing the entering impact to be taken some distance back from the corner of the teeth. Use of negative axial rake also tends to build up pressure between the cutter and the work and prevents the cutter from digging in at the entering part of the cut. It also tends to absorb all backlash in the machine before the nose radius or chamfer enters the cut.

The three different conditions shown in Fig. 5 may be encountered when the cutting edge enters the cut. At (A) the face of the work where the cutting edge enters is parallel with the centerline of the milling cutter. The combination of the actual blade angle *B*, the radial rake angle and the bevel angle (side cutting edge angle on single point tools) is such that it develops an effective negative axial rake angle *A*. If the effective negative axial rake angle is 3-5 deg. greater than the angle on the face of the part, the cutting pressures will be held to a minimum and will tend toward maximum cutter life. If this angle is larger than necessary it will tend toward increased power. The radius or chamfer should be the last portion of the cutting edge to enter the part.

At (B) in Fig. 5 the cutting edge enters the cut parallel with the entering face of the part. This combination of the actual blade angle *B*, the radial rake angle and the bevel angle is such that it develops an effective negative angle *A* which actually matches with the surface on the entering side of the part. This creates the maximum impact load and tends to shatter the cutting edge. This condition should never be allowed.

At (C) the radius or chamfer of the cutting edge hits the part first. This condition can develop from using too small an effective negative axial rake angle which results from the wrong combination of actual blade angle *B*, the radial rake angle and bevel angle. This will cause the radius or chamfer, which is the weakest portion of the cutting edge, to chip out or break down rapidly due to the impact load. It is important that a cemented carbide tipped milling cutter never be used under this set of conditions.

The axial rake angles in use at the present time usually vary between 3 deg. negative and 15 deg. negative. An angle of 8-10 deg. negative is recommended for face and straddle mills which cut past the part. For optimism cutter performance a cutter should be designed with the proper axial rake angle to meet conditions outlined at (A), Fig. 5. Experience on applications involving milling up to a shoulder indicates that a negative axial rake angle of approximately 3 deg. retains the inherent advantage of a negative angle and at the same time assures that the part will be held to size by keeping the side pressure to a minimum.

Bevel Angle

The bevel angle (see Fig. 4) on a face or straddle milling cutter serves the same purpose as the side cutting edge angle on a single point tool. It protects the chamfer or radius on the corner of the teeth when the face milling cutter first touches the part and for that reason tends to increase the cutter life.

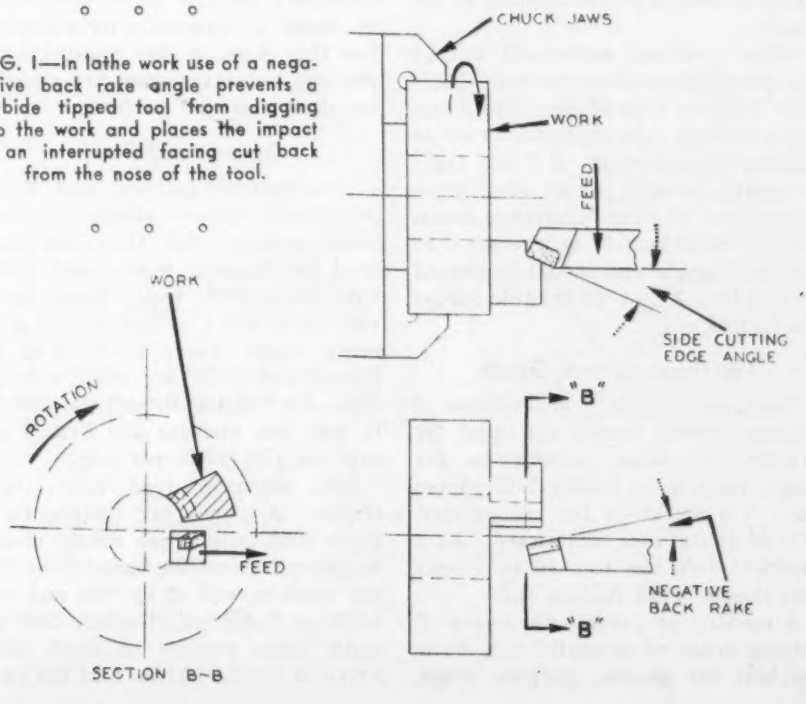
Fig. 6 (A) shows a face milling cutter with a 0 deg. bevel angle entering a cut which has a 90 deg. included angle. This results in short cutter life because of the increased impact along the entire cutting edge, including the chamfer or radius. If a slight bevel angle is ground on the cutter as shown at (B), the initial impact load will be moved away from the weak chamfer or radius to a point of greater strength and the life of the cutter will be materially increased.

At (C) the same face mill as used at (A), Fig. 6 is used for milling work which has an angle *X* on the entering side. At the beginning of the cut angle *X* is comparable to a draft angle on a forging and allows the chamfer on the cutter to touch the work first and takes the full initial impact load of the cut, dulling this portion of the cutter rapidly. The life of the cutter can be materially increased if the bevel angle is made 3-5 deg. greater than the maximum angle *X* on the part. This permits the impact load of the cutter to be taken at a strong portion of the cutting edge.

For most face and straddle milling operations where the cutter mills past the part, a bevel angle of 15 deg. is usually satisfactory. However, where a 15 deg. bevel is not sufficient to assure the chamfer or radius entering the cut last, the bevel angle should be increased up to as much as 35 deg. if necessary. When a 0 deg. bevel angle must be used, the radial rake angle should be 3-7 deg. negative. The width of the bevel angle should be sufficiently large to cover the full depth of the cut.

The relief angle (see Fig. 4) along the bevel angle or along the outside diameter should be ground between 4 and 7 deg. up to an edge. Use 4 deg. for the harder steels and gradually increase the relief angle until it is 7 deg. for the softer free machining steels. The clearance angle behind the

FIG. 1—In lathe work use of a negative back rake angle prevents a carbide tipped tool from digging into the work and places the impact of an interrupted facing cut back from the nose of the tool.



relief angle should be ground sufficiently large to permit the corners *X* to clear the cut up to a land 3/64-1/16 in. wide behind the cutting edge. If after use the land tends to widen rapidly due to wear, the relief angle should be increased. If the breakdown of the cutting edge is due to chipping, reduce the relief angle.

Chamfer or Radius

A chamfer or radius should be ground on all milling cutters to remove the extremely frail sharp corner which is inclined to flake off. A radius gives the greatest strength and should be used if suitable grinding equipment is available and the finished work specifications permit.

On fly cutting tools a radius can be easily ground free hand on all single point tool grinders. A 1/32 in. radius is recommended, ground at the same relief angle as on the bevel or outside diameter and the face. This radius may be enlarged where work specifications indicate a large fillet.

Multi-Tooth Cutters

If work specifications permit on multi-tooth, it is preferable to chamfer the teeth as a chamfer can be ground more accurately than a radius with present-day equipment. A 1/16 in. x 45 deg. chamfer is recommended ground at about 1 deg. less relief than on the outside diameter at the bevel. The two corners left by the chamfer should be brushed lightly with about a 320-grit silicon carbide stone to remove the sharp corner. However, if an accurate cutter grinder with radius attachment is available, radii should be ground on the cutter to give maximum strength.

If part specifications permit, the radius should be ground as shown in Fig. 7. This confines the angular movement *W* to less than 90 deg. and eliminates any chance of the grinding wheel digging into the cutting edge on the outside diameter or face. When no radius or chamfer is permitted, the corner should be broken slightly using a 320-grit silicon carbide stone. Breaking the edge will eliminate chipping. A reduced number of pieces per grind usually results when no chamfer or radius is used.

If the relief angle alone is not sufficient to permit the corners *X* (Fig. 4) to clear the cut, a suitable clearance should be ground up to a land 3/64 to 1/16 in. wide behind the cutting edge. Generally this operation is unnecessary.

Face

The face of the cutter, Fig. 4, should be ground at 2-4 deg. concave from the toe toward the heel and the clearance below the heel should be ground at 5-7 deg. making the face ⅛-3/16 in. long. This increases the distance between the braze line *V* and the cut, and eliminates pickup of work material. When grinding the relief angle behind the cutting edge on fly tools, the relief angle should be maintained the same as on the bevel angle to simplify the blending of the radius.

When grinding multi-tooth cutters the relief angles along the face should vary between 2 and 5 deg. Use 2 deg. for a slotting type of cutter to aid in holding the slot width. A 5 deg. angle is usually suitable for all other types of cutters. The face clearance angle, Fig. 4, should be 2-4 deg. greater than the relief angle and should be ground up to a land 3/64-1/16 in. wide behind the cutting edge.

Tip Thickness and Grade

Minimum trouble is encountered if thicker carbide blanks are used for exactly the same reasons as for single point tools taking interrupted cuts. Tip thickness for milling cast iron is fairly well established. As a practical rule use tips 30 to 40 per cent thicker when milling steel.

A medium or general purpose steel cutting grade of cemented carbide is the best for general purpose rough and finish milling of steel. A finishing steel cutting grade can be used where the depth of cut is not more than 1/16 in. If the medium steel cutting grade breaks down by chipping and *all other conditions have been carefully checked,* a softer steel cutting grade should be tried.

A finishing grade of straight tungsten carbide has been used to take extremely shallow finish cuts (0.005 in. deep) at unusually light feeds of less than 0.001 in. per tooth and will produce a surface smoother and flatter than a ground surface.

Speeds and Feeds

Observations indicate that higher peripheral speeds should be used when milling steel than are being used for turning, boring and facing with single point tools. These speeds vary with the hardness of the steels being milled. For a hardness of 300 Brinell and under use 500-700 ft. per min.; for 300-400 Brinell use 250-500 ft. per min. and for 400 Brinell and over use 150-350 ft. per min.

The optimum feed rate (table travel) in inches per minute for a given steel milling job should always be determined on the basis of the feed per tooth instead of by "cut and try" methods. Table travel equals feed per tooth times number of teeth times r.p.m. A 0.005-0.008 in. feed per tooth

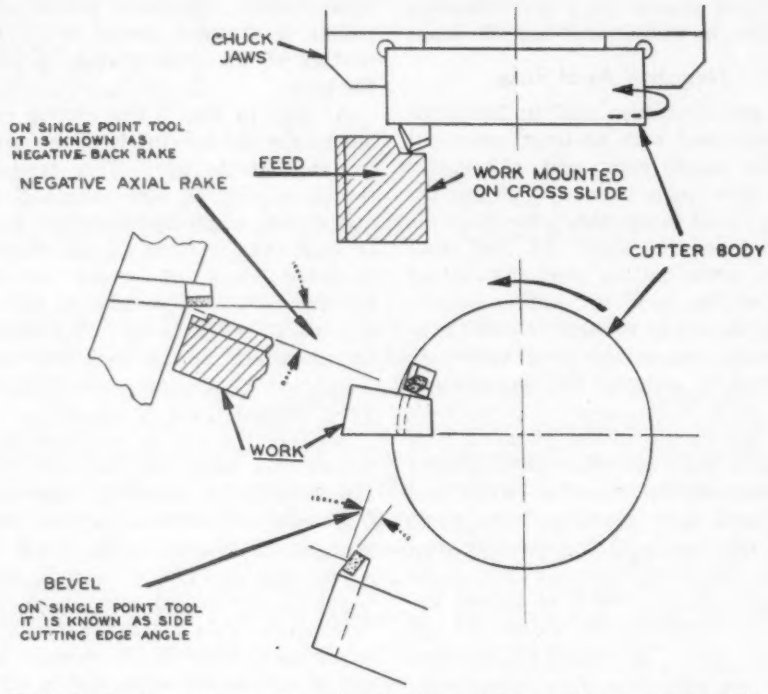


FIG. 2—By transposing cutter and work shown in Fig. 1, there is obtained the equivalent of a fly face milling cutter. The same cutting conditions still obtain.

o o o

will produce the maximum number of accurately finished pieces per grind when using face mills or straddle mills which cut past the work. With lighter feeds the number of finished parts per grind will decrease.

If the milling machine is in good condition and has ample power available, the fixture is rigid and is designed to bring the cut close to the milling machine table, and if the milling cutter is properly designed, the feed per tooth can be increased to 0.015 in. without any detrimental effect on cutter life. When using slotting cutters or other cutters which cut up to a shoulder indications are that a feed per tooth which is about 50 per cent of that used for ordinary face mills and straddle mills will give good results. This amounts to about 0.0025-0.004 in. feed per tooth. When this type of setup has real rigidity, the feed per tooth can be increased to about 0.008 in.

Number of Teeth and Power

When the design of the part being milled necessitates that the corner of the cutter have a large sized radius, as heavy a feed per tooth as possible should be used to reduce the chip thinning effect where the radius blends into the face.

A large number of the milling machines in use today do not have motors larger than 5 to 7½ hp. This limited power restricts the work which can be handled satisfactorily with cemented carbide tipped cutters on these machines and it becomes important that the power available be taken into consideration before starting any steel milling operation.

The power required to mill a certain cut on a given part on a given milling machine depends on:

1. The r.p.m. of the cutter
2. The number of teeth in the cutter
3. The feed per tooth.

The optimum feed per tooth and the optimum peripheral speed is quite definitely determined by the material being milled. This leaves only the number of teeth in the cutter to be considered to keep within the power available. It may be quickly found that the cutter can only have a small number of teeth and in many cases fly cutting (in which the feed per tooth is the feed revolution of the cutter) may have to be employed as shown in Fig. 3.

The following formula provides a means of roughly estimating the number of teeth required in a milling cutter in order to keep within the power available.

$$N = \frac{0.56 \text{ Hp.}}{DFRW}$$

$$\text{Hp.} = 1.8\ DFNR\pm$$

where D = maximum depth of cut, in.
F = Feed per tooth, in.
Hp. = Motor horsepower
N = Number of teeth in cutter
R = R.p.m. of cutter
W = Maximum width of cut, in.

A time-honored practice with high speed steel cutters has been to see that at least two teeth are in contact with the work at all times. At the higher speeds used with carbide cutters this is not essential since there is sufficient momentum to assure smooth cutting action.

The two above formulae are based on 1 hp. being required to remove ¾ cu. in. of steel per min. It is also based on the cutter needing 35 to 40 per cent more power to take a cut when it is dull than is required to take the same cut when it is sharp.

Cutter Body Design

The basic milling operations on which cemented carbides have been used are:

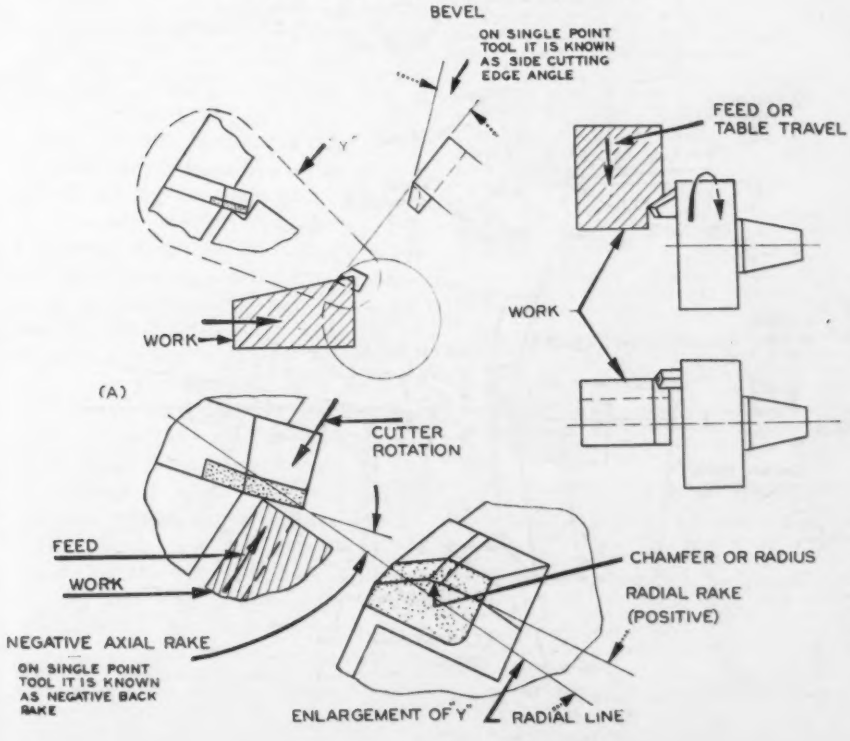
1. Face or straddle milling past the part
2. Face or straddle milling along a shoulder
3. Slotting
4. Plain milling (very limited).

There are two general types of cutters which should be considered: Solid and inserted blade type. Bodies can be made of steel or high tensile cast iron. When a solid body is used ample chip room should be allowed and the carbide cutting edge should be rigidly backed up. There are cases where thin bodies are necessary and in this case the solid type is the only one that can be used. The cemented carbide blanks can be brazed direct to the solid cutter bodies by a low temperature braze.

In milling steel with carbides, it is highly desirable to use a massive milling cutter body in order to take advantage of the flywheel effect. This reduces the shock or rebound from the impact of the cutting edge against the work, provides a smooth cutting action and results in an increased number of pieces per grind and less machine repair. It also enables the machine to level out momentary peak loads considerably greater than that of the rated motor capacity. When it is not possible to incorporate a sufficient amount of mass in the cutter body auxiliary flywheels can be added

o o o

FIG. 3—Action of a fly milling cutter tool in entering the work. These sketches should be compared with the tool action in Figs. 1 and 2.



to the spindles or arbors to smooth out the operation.

Diameter of Cutter

When determining the correct cutter diameter it is desirable to take full advantage of the fact that the smaller diameter cutters have to be run at more revolutions per minute than larger diameter cutters in order to obtain a given peripheral speed. The high revolutions per minute give more teeth per minute and permit a higher table travel for a predetermined feed per tooth. The small diameter face mill helps to do a given job faster than the large diameter face mill because it reduces the length of the approach cut. In general the cutter diameter (as measured at the tooth radius or chamfer) should exceed the width of the work by 25 to 40 per cent.

Conventional methods of holding the blades or tool bits in the cutter body can be used. Heavier blade cross-sections should be used than for the corresponding sizes of high speed steel cutters. The following tabulation shows suggested blade or tool bit thicknesses for various body diameters.

Body Diameter, In.	Blade or Tool Bit Thickness, In.
2¾ and 3	⅝
4 and 5	¾
6, 7, 8 and 9	1
10 and larger	1¼

The blades or tool bits should be allowed to project a sufficient distance from the cutter body to provide ample chip space, or clearance space must be milled in the body. This latter method is preferable on most applications and it is essential wherever heavy cuts and heavy feeds are used. In any event the tools should never project beyond their support more than the shank thickness below the tip. In order to stay within this limit it may be advisable to weld a steel support underneath and behind the blade or tool bit positions before milling the tool slots.

All cutter bodies should be made to facilitate the free flow of chips from the cut. Any tendency to restrict this chip flow will reduce the number of pieces per grind and will ruin the finish on the cut.

Fly Cutting

It may be frequently found that because of machine power limitations the desired feed per tooth, at optimum peripheral speeds for carbides, cannot be obtained with multiple tooth cutters of ordinary design and it may be necessary to use only a single tooth in order to obtain the proper load per tooth without exceeding the available horsepower. Such single tooth cutters are usually employed for shallow cuts through 3/32 in. A typical single tooth cutter is shown in Fig. 3. When the depth of cut is greater than 3/32 in. it is advisable to increase the number of teeth but split-up the total depth of cut into steps, with each tooth cutting a separate step. This gives a smoother cutting action and leaves a flatter surface than a single tooth cutter. For example with a two-tooth fly-cutter the teeth are spaced at approximately 180 deg. One tooth takes the heavy roughing cut and the second tooth the lighter finishing cut. The roughing blade or tool bit is set ahead of the finishing blade radially a distance of 1/16 in. and the finishing blade extends axially ahead of the roughing blade.

Assuming for example that a total depth of cut 5/32 in. is being taken, the finishing blade takes a cut of only 1/32 in. depth while the roughing cut removes 1/16 in. In two-tooth cutters, a depth of finishing cut 25 to 35 per cent of the total depth of cut is generally satisfactory.

Much smoother cutting action can be obtained with fly cutting when applied to cuts ½ in. deep or more if the number of teeth is increased to three or four. In this case the depth of the rough cut will be divided between two or three teeth which would still leave only one tooth for finishing.

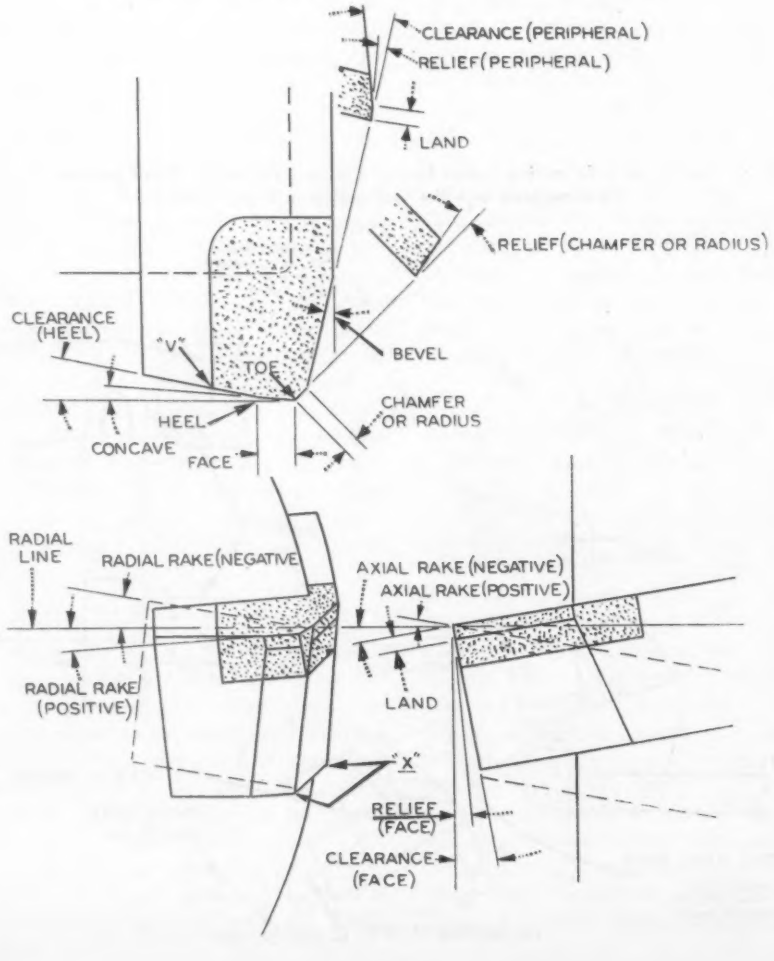
When fly cutters are used the blade or bits can be resharpened free hand on single point tool grinders and set to a gage in the holder or body without removing the latter from the machine.

Machine Requirements

The fundamental thought to be kept in mind at all times when considering any milling operation is *rigidity*. This applies to both the machine and the method of clamping the work. Machines rugged enough to withstand all forces and shock incidental to the operation should be used. The life and accuracy of the milling machine can be prolonged, the quality of the work can be improved, cost per finished piece lowered and

o o o

Fig. 4—Definition of angles on a carbide tipped milling cutter.



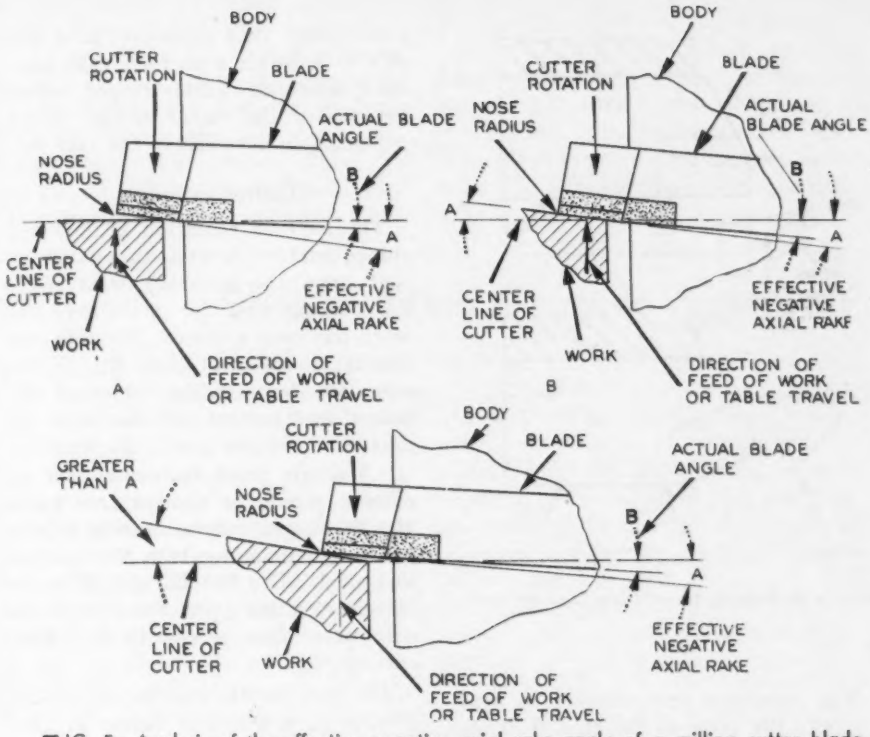


FIG. 5—Analysis of the effective negative axial rake angle of a milling cutter blade with respect to the work.

o o o

shut-down periods of the machine reduced if the following suggestions are used.

1. Backlash in the feed screw should always be kept at a minimum. Machines with backlash eliminator ought to be used.
2. Table gibs should be adjusted to give the table a snug sliding fit.
3. End play in the machine should be kept at an absolute minimum.
4. Because of the higher speeds and increased feed rates, lubrication should be checked to make certain that it is adequate and properly applied.
5. Machine should be inspected periodically to eliminate sloppy fits that cause chatter.
6. The knee and saddle should be securely locked before starting a cut.
7. When the tapered hole in the machine spindle is used to centralize a face mill, it should be clean so that a uniform metal-to-metal fit for the full length of the shank is assured.

The general nature of the work and the proper clamping of it have a direct bearing on the success or failure of any milling operation. The increased feed rates with carbide tipped cutters reduce the cutting time to an amount where loading and unloading time of the part being milled becomes a major problem. Because of this it is necessary to use fixtures with heavy wall sections and actuate them rapidly by either air or oil pressure. The best arrangement is to use an automatic cycle type of milling machine which has a fixture or fixtures which can be unloaded and loaded by the operator during actual cutting time. The following points are of importance in good fixture design:

1. Hold the work rigidly but still allow it to remain in a state of "rest," without torsional or bending strains.
2. Clamp the part so as to keep the surface being milled as close as possible to the machine table.
3. If the surface being milled must be high above the table, the surface of the fixture taking the thrust should support the part directly behind the surface being milled.
4. Cut and table as close as possible to the spindle nose of the machine.
5. The milling fixture should be heavy enough to absorb forces and vibration created by clamping and cutting without springing or deflecting the milling machine table.
6. The construction of the fixture should allow for the free flow of chips from the cut.
7. All cutting pressures should be against rigid stops and supports, never against the clamps.
8. Minimum distortion results if the point of clamping is as close as possible opposite the point of support.
9. Where work sections are thin, it may be necessary to provide additional locking spring plungers or similar devices to adequately support the work.
10. All milling fixtures should be aligned with the table slots by inserted keys on the bottom of the fixture.
11. Equalizing clamps should be used to provide for variations in size and shape of the part.
12. All locating and supporting surfaces of a fixture should be permanently fixed or have adjustable fixed stops. Only the clamping surfaces should be movable.
13. The bottom of the fixture should be cleaned and all nicks and burrs removed before clamping it to the milling machine table.
14. The points of location and support should be no larger than absolutely necessary and positioned near the extremities of the part but still as close as possible to the surfaces being milled.
15. Burring time can be reduced to a minimum on parts which require several cuts if the direction of the feed and the various cuts are positoned so as to throw most of the edges requiring burring on the same side.
16. Where it is necessary to clamp the work from the sides, the clamps should also pull the work against the supports.
17. When a stop and a support surface on a fixture form a sharp corner, the corner should be relieved to simplify cleaning.
18. When clamping, do not use wrenches on hand knobs.

Operating Precautions

The following precautions should be observed when using cemented carbide tipped cutters:

1. Never disengage spindle while feed is engaged.
2. Always have the cutter rotating before feeding the work up to the cutter.
3. Make certain that the rapid traverse is out and the regular feed in before the work contacts the rotating cutter.
4. When stopping the machine, first throw out the feed and then immediately disengage the spindle clutch.
5. Never allow the cutter to idle in the cut as the rubbing of the cutting edges against the work has a dulling effect on the cutting edges.
6. Keep the cutter rotating when returning the table to starting position after a roughing cut.
7. After a FINISH cut, the work should be removed before returning the table.

When face milling on a universal knee type of milling machine, the table should travel normal to the centerline of the cutter spindle, or be set to travel slightly past at an angle equivalent to 0.002 in. in 18 in. so that the trailing portion of the cutter will not spoil the work. When face milling on a plain type milling machine of either the horizontal knee or the vertical type, the angular relation of the milling machine spindle to the direction of table travel is such that the trailing portion of a properly ground cutter will not spoil the finish on the work. This also applies to the manufacturing and planer type of milling machine.

Dragging Work Across Cutter

Indications are that increased cutter life is obtained when the work is not dragged across the cutter on the return stroke. The reason is that the milling cutter builds up a pressure between the work and the cutter to the extent where the cutter actually takes a cut which is shallower than the machine setting. On the return stroke the work springs back to its normal position and the cutting edge drags across it. This causes chipping when the cutter is not rotating.

If the work cannot be removed before it is returned to the starting position, the cutter should be kept rotating on the return stroke. This will permit it to cut its way across the work, although it is liable to ruin the finish on the work and also increase the wear on the cutting edges. The ideal type of cemented carbide cutter setup is one where either the cutter is automatically moved to clear the work or the work moved to clear the cutter on the return stroke.

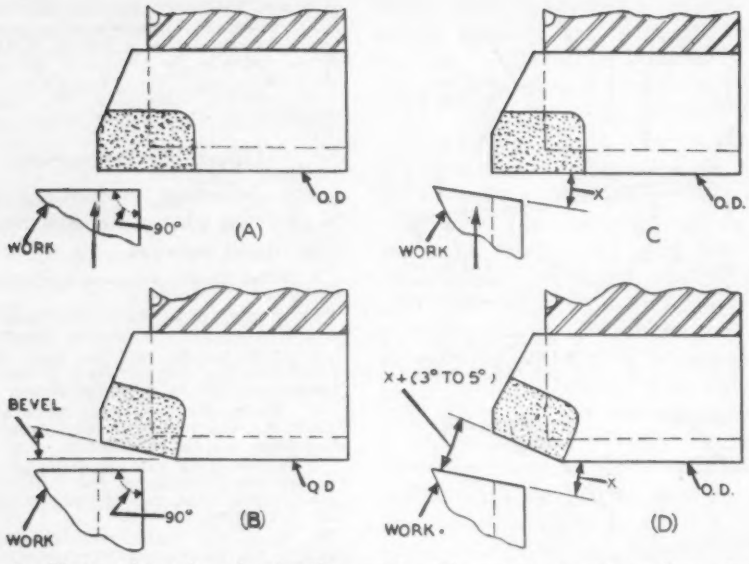

Fig. 6—Choice of bevel angle of milling cutter with respect to entering face of work.

o o o

Dry Cutting Favored

All indications are that the greater cutter life is obtained when milling steel dry because the chips are thin and the major portion of the heat flows into them until they seem to approach a plastic state. In this condition they seem to wear the cutting edge much less than when they are chilled by a coolant.

If proper consideration has been given to chip space but the chips are inclined to stick to the cutting edge there is always danger that they will ruin the cutting edge when it hits the work again. A strong air blast directed against the cut will remove the chips as they form. Chips have been removed from face mill cuts by directing an air blast through machine spindle and the center of the cutter at pressures as high as 150 lb. per sq. in.

The flying chips which result from the high speed milling of steel with cemented carbide tipped cutters can become a hazard to the operators in the vicinity of the milling machine and suggest the use of simple chip guards.

Climb Milling

Indications are that increased cutter life is obtained with "climb milling." This idea can be applied to all types of milling cutters which mill up to a shoulder. The main reason for the improved results from climb milling is that each tooth makes a chip of a definite thickness at the time it enters the cut. With conventional milling (also known as up-cutting) every tooth starts with a chip which has a zero thickness and reaches its maximum near the end of its cut. This maximum chip thickness is practically the same as the chip thickness at the beginning of the climb cut. At the beginning of a conventional cut there is an abrasive action until sufficient pressure has been built up to where the cutting edge penetrates the work.

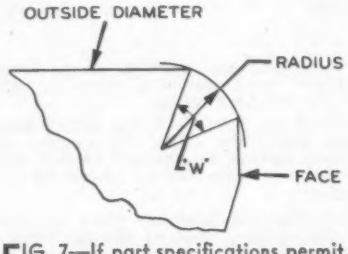

FIG. 7—If part specifications permit, the nose radius should be ground as shown, limiting the angle W to less than 90 deg.

o o o

Climb milling must be applied with caution. All milling machines are not designed for climb cutting. Machines with a backlash eliminator in the feed nut are suitable.

Wherever possible face mills or straddle mills should always be used in preference to plain mills because they operate with reduced cutting pressures, permitting the use of increased feeds and resulting in longer cutter life. In a plain mill it is difficult to maintain a uniform rake angle with cemented carbide tipped cutters because of the cutter width. These problems do not exist in the face mill.

Cutter Grinding

The surface condition of any machined surface depends to a large extent upon the accuracy with which the cutting tool for machining the work has been ground. For this reason it is essential that the proper technique for grinding cemented carbide tipped cutters is followed if the maximum results are to be obtained.

All single point tools used for fly cutting should be ground free hand. Use 60-30 grit silicon carbide wheels for rough grinding both the carbide and steel. Use 180-220 grit diamond wheels to finish grind the carbide tip only to produce a smooth and keen cutting edge.

All multi-tooth cutters should be ground on a tool and cutter grinder equipped with suitable rugged fixture. The machine must be kept in first-class condition with a free running but snug spindle, snug gibs and straight and true ways. Either the cup wheel or straight wheel method of grinding is satisfactory. Use the same grit wheels as mentioned above for fly cutting tools.

Before fly cutters or multi-tooth cutters are used the cutting edges should be brushed lightly with a 320 grit silicon carbide stone at 45 deg. angle to the face of the tooth to remove any feather edges.

Cutter runout should always be checked before using any multi-tooth cutter. For best results it should be kept within the value shown in the table below.

On the outside diameter, no consecutive tooth should have a variation greater than one-half of the total runout.

When several cutters have the same number of teeth and are mounted on an arbor so that they will mill several surfaces on the same or several parts at the same time, a much smoother cutting action will be obtained if the cutters are keyseated to stagger the teeth. This will increase the number

	Permissible Runout, In.			
	Roughing Cuts		Finishing Cuts	
Cutter Diameter	Face	O.D. & Chamfer	Face	O.D. & Chamfer
Up to 12 in.	0.001	0.002	0.0005	0.0015
12 to 16 in.	0.0015	0.003	0.00075	0.002
Over 16 in.	0.002	0.004	0.001	0.0025

of pieces per grind quite materially.

If the cutter is not located properly in relation to the work when face milling a part, an objectionable burr may develop on the side where the cutter enters the work. This can usually be eliminated by increasing the cutter overhang on the side where the burr develops by a slight amount.

Multi-tooth carbide tipped milling cutters are usually difficult to handle because of their size, shape and weight and the cutting edges are often damaged through careless handling. Special wooden boxes or trays, with covers which can be fastened in place by screws, aid in eliminating this difficulty. The cutting edges on single point tools used in fly cutter bodies are also easily ruined by improper handling. This can be eliminated by providing suitable boxes to hold several of these tools in a vertical position.

Shot Blasting Gears to Improve Fatigue Life

SHOT blasting is being utilized in production at transmission plants of Chevrolet Motor Division to substantially increase the fatigue strength of gear parts.

Surface peening by means of shot is effectively carried out at Chevrolet's Toledo plant by means of a cleverly devised fixture which exposes all wear portions of the gear teeth to direct and right-angled blast in a closed chamber. This conforms to requirements outlined in recent papers by J. O. Almen, of General Motors Research Div., who specifies that the most effective use of the surface peening technique lies in directing the shot at 90 deg. angle to the surface at the ends and the roots of the gear teeth.

See Mr. Almen's paper, "Improving Fatigue Strength of Machine Parts," THE IRON AGE, June 10, 1943, page 65.

In the production procedure at Toledo, gears are mounted on an arbor which fits onto the open end of a Y-shaped fixture or yoke. Rubber belting slipped over this arbor is used to rotate the gears at a preselected speed. At the same time the entire fixture oscillates on its longitudinal axis, at a right angle to the arbor axis. This latter movement covers an arc 45 deg. each way from horizontal. The entire fixture is mounted on a vertical arm which swings out to permit ready positioning of the gears, and then swings back into a standard Pangborn Rotoblast shot-blasting machine.

The showers of shot impose steady wear on the supports of this fixture necessitating replacements at regular intervals. Angle iron is used for the forward corners, this having been found the best wear-resistant material.

No. 26 chilled steel round shot of 0.025 to 0.035-in. diameter is used. A wheel of 13-in. diameter, turning at 3300 r.p.m., mounted above the gears, directs the shot at approximately 200 ft. per sec. The shot then drops through grating on the floor of the installation and is returned through a closed circuit to the impeller wheel. The size of the shot is controlled by regular sift checks.

Installations for the shot blasting of gear parts in other Chevrolet plants utilize air pressure to produce a high velocity shot stream. Here the cabinet in which the parts are placed is usually mounted directly above a mixing chamber into which the shot is returned through open grates in the floor of the cabinet. In this chamber, air and shot are mixed and conducted through a rubber tube to a nozzle in the cabinet.

At Toledo, the shot blasting is utilized on first speed gears and first speed countergears of a 1½-ton truck transmission. The low-speed gears are mounted on the fixture three at a time, as illustrated, the countergears one at a time. Rotation of the pieces is at 22 r.p.m., actuated by a ¼ hp. motor with speed-reducer and crank action. This motor also serves to swing the gears back and forth through the 90 deg. arc on the longitudinal axis.

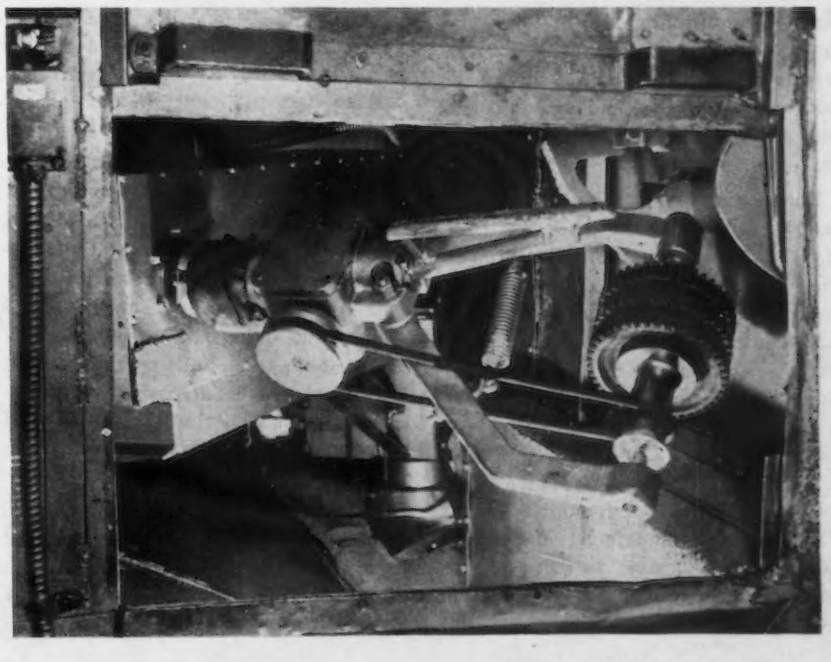
The shot spray is left on for 30 sec. Research has established that a perfectly controlled cycle is 16 sec., but the longer period is specified to permit less expert supervision. A longer cycle than 30 sec. has been proved unnecessary.

The gears which are thus treated are of SAE 8620 steel, previously hardened. There is no subsequent grinding, for obviously any such operations following the shot-blasting would remove the surface and relieve the compressive stresses induced during the peening, thereby destroying the beneficial effect already achieved.

This installation first went into use in May, 1941. Before that time, dynamometer tests gave the gears a life of 2½ hr. at torque of 200 ft.-lb., the maximum engine torque in installed positions in engines being 170 ft.-lb. By use of the shot-blasting technique, these pieces now stand up for 40 hr. under the 200 ft.-lb. torque test.

o o o

THIS is the fixture devised by Chevrolet for its shot blasting of gears at Toledo. Three first speed gears are mounted ready to be moved into the chamber for peening treatment. At this point the rear arm of the fixture is nearly at the top of its 90 deg. arc. When shot blasting begins, it will swing downward while the arm in foreground rises, this oscillatory movement being actuated by the same motor which drives the rubber belting slipped over the arbor on which the gears are mounted.



China's I

A LATHE made by the Chinese Industrial Cooperatives is unloaded by two students at one of the Cooperatives' schools for technical and mechanical training. Lathes in China are hard to get, and carefully cherished. This one will be used in a machine shop course.

HEAVY industry in unoccupied China has made a small but interesting beginning, recent information received from that country reveals. Before the invasion by Japan, virtually the entire ferrous output of the country was concentrated in areas now occupied, notably in Manchuria, Hankow and Shanghai, so that the present, new-born ferrous production of free China has been achieved over tremendous obstacles and with considerable improvisation and experiment.

The output of pig iron in 1942 was 30,000 tons, increased from less than 12,000 in 1941; that of steel, 10,000 tons, increased from 6000 in 1941. Most of the iron and steel is produced in Szechuan province, in which Chungking is located. The ore deposits found to date in southern China are in small pockets, so of necessity the plants are small. The largest is that owned by the government's National Resources Commission, which moved 40,000 tons of machinery and materials from Hanyang to Chungking. Privately owned iron and steel production equipment totaling 1150 tons was brought from works in occupied China into the free territory. A good deal of equipment which had been ordered was lost by capture of the Burma Road.

The best pig iron has been produced by roasting the ore, then smelting it in very small furnaces, a few hundred pounds at a time. The iron has an analysis in the neighborhood of 0.15 per cent P, 0.6 to 0.8 per cent Mn, 0.04 to 0.08 per cent S, and 0.2 per cent Si.

The Chinese are at present investigating the possibilities of sponge iron, with the relatively small size of ore deposits a point in favor of the process. One sponge iron plant is being constructed by the government and a 2-ton plant, using the Anderson process, is about to be built by the Chinese Industrial Cooperatives at Shuangshihpu, in the northwest. Typical of Chinese improvisation, the ore here will be ground in grist mills, then separated magnetically.

The Cooperatives are also erecting a gray iron furnace at Shuangshihpu, after a design of the 1870's. The tuyere is cooled by means of two lines for water intake and outlet to a wooden tub for cooling. A ton of gray iron a day will be produced in the furnace, which is of 90 cu. ft. capacity. A Roots blower of 200 cu. ft. capacity per min., driven by a 2 hp. engine running on alcohol, and supplemented by two native piston blowers of about 80 cu. ft. per min. each, will supply the blast.

Steel is being made in 1½-ton acid bessemer furnaces with side blow; maximum air pressure is about 5 lb. The ingots cast from these bessemers weigh 440 lb. The phosphorus content in the iron has caused considerable trouble, making it impossible to produce satisfactory steel with a carbon content higher than 0.2 per cent. Chinese engineers now in this country are investigating the "washed metal" process, a method used to a considerable extent here in the 1880's. The bottom of the furnace, in this process, is not durable but is intended to supply ore and lime to oxidize metalloids and give a basic slag. The furnace is not allowed to reach a high temperature because the phosphorus would then leave the slag and return to the

Infant Heavy Industry

. . . Free China is adapting smelter and furnace designs from the earlier days of American and European iron and steel production, in an effort to "grow into" industry. Her ferrous and other heavy industry output, while small, has grown swiftly in the past two years.

° ° °

metal. The furnace is tapped when the steel contains 2.00 per cent C, too high a temperature being required to obtain a lower carbon content.

Chinese steel is also being made on a small scale by the old crucible process, with excellent results. Some open hearth furnaces have been set up, but in at least one case considerable operating difficulties have been encountered. Wrought iron is being made by hand puddling methods, but this apparently is still on a very small scale.

Bars of soft steel down to ⅜ in. diameter are being made. The ⅜ in. bars are used for wire drawing to ⅛ in. and less. The steel, with its low carbon and high phosphorus content, is very ductile.

The two or three rolling mills have been made principally from old parts. Shafts from river steamers are used, with rolls up to 15 in. in diameter of cast iron. A recent attempt to make breakdown rolls 18 in. in diameter of chilled steel was unsatisfactory; Chinese engineers now in this country hope to obtain help here in solving this production problem, among others.

Production particularly badly needed at present is butt welded pipe ½ to 3 in. in diameter, steel for shafting, and 16 gage and thinner sheets for oil and gasoline drums. The urgent need for the sheets has been occasioned by the fact that the Chinese are drilling for oil in Kansu province, in hitherto untapped fields. Refining is done by the topping distillation process. The principal problem is transportation, as is reflected by an August, 1943, price of $30 (Chinese dollars) per gal. in Kansu and $400 per gal. in Chungking. Production of industrial alcohol, diesel oil, vegetable oil fuels and native crude oil increased from 5,500,000 gal. in 1941 to more than 9,000,000 gal. in 1942.

In 1942 free China produced 1500 sets of machine tools and 450 power generating sets. Figures on radio receiver and transmitter production are not available, but output exceeded the government's production plan by 142 per cent.

The country has 1915 privately owned enterprises using power and employing more than 30 workers, of which 584 are in or near Chungking and 352 elsewhere in Szechuan. Hunan province has 368; Kwangsi, 173; Shensi, 170; Kansu, 63; and Yunnan and Kweichow, each 49. The industrial distribution of these factories is as follows:

	Per Cent
Machinery	28.5
Chemicals	27.2
Textile and clothing	22.8
Metallurgical	7.1
Food	5.1
Electrical equipment	3.2
Printing	2.1
Others	4.0

Table I summarizes production increases in the major privately owned industries from 1940 to 1942.

TABLE I
Production Increases in Major Privately Owned Chinese Industries

Industry	1941, Per cent (1940=100)	1942, Per cent (1940=100)
Iron	259	555
Steel	122	146
Coal	113	123
Prime movers	200	214
Machine tools	133	137
Acids	105	237
Caustic soda	300	324
Bleaching powder	348	458
Industrial alcohol	104	111
Machine-spun cotton yarn	253	361
Machine-milled wheat flour	139	145

From Guenther Stein, "Far Eastern Survey," Aug. 11, 1943.

In addition the Chinese Industrial Cooperatives have 57 machine and metal works, where lathes, shaping machines, looms, spinning and carding machines, and workshop equipment are produced. The Cooperatives also operate coal mines, and produce coke and charcoal. There are 111 mining cooperatives, 73 of them in the northwest. In the Cooperatives' Bailie schools, about 200 boys a year are given a good technical and mechanical education. Western engineers who can work with improvised methods are still badly needed, as is the technical advice which Chinese engineers obtain in this country.

From present indications, industrialization of China will be accomplished through relatively small, decentralized plants, a system favored not only by the raw material distribution, but by the present distribution of population and organization of Society. It has apparently become recognized in China that its agriculture, on which the entire economy now rests, must be mechanized if the standard of living is to be raised. The agricultural workers displaced by mechanization must be employed in widely distributed industry. Well informed reports indicate that the Chinese intend to accomplish this industrialization themselves, looking forward to the day when they can trade on a large scale with Western nations, rather than as a "colonial" nation with small purchasing power.

Re-Galvanizing of Welded Joints

GALVANIZED structures and sheets from which the original galvanizing is burned off during the welding process are successfully re-galvanized on the job with an alloy called "Galv-Weld" to prevent corrosion. This method of re-galvanizing can be applied to seams made by arc and gas welding. The intense heat of welding burns off the coating of zinc and exposes the bare metal adjacent to the weld. In most cases it has been impractical to re-galvanize the bare spots by the hot-dip method which requires a heated receptacle containing molten zinc and which is impossible in the case of large structures.

This process of re-galvanizing is quite simple and with a little practice any experienced welder or welder's helper can Galv-Weld a seam. In its barest essentials, the process consists of rubbing over the heated bare spots a stick of low melting galvanizing alloy to form thereon a smooth coating of metal which will have all of the corrosion resisting properties, as well as the wearing qualities of the original galvanized coating. The material may be used in bar, powder or liquid form but usually a bar is found to be the most practical for structural work.

After a weld is made it is rubbed briskly while still red hot with a brass wire bristled brush to clean the weld. Then a bar of the low-melting alloy is rubbed along the hot weld and over the adjacent surface to fix a deposit of the alloy and while this galvanizing alloy is in a liquid state the wire brush is again applied to spread the alloy evenly over the entire weld. Although this galvanizing alloy can be applied by utilizing the stored up heat in the welded sections, re-galvanizing can also be done by re-heating the weld to approximately 600 deg. F. The alloy itself melts at 450 deg.

One interesting feature is the fact that where there is enough heat to damage the original galvanizing there also is enough heat to re-galvanize with the Galv-Weld process. It was further discovered that the melting temperature of the residual heat extends fully as far from the actual position of the weld as the outside edges of the bare spots. The importance of this is apparent when one considers the fact that the bare spots may extend as much as 1½ to 2 in. from the position of the weld. It is claimed that no deleterious effects will be produced at the welds and bare spots which may develop during the welding will be left with a galvanized coating. The coating is said to be not only as good, but actually superior to the original coating insofar as toughness, long wear, quality and appearance are concerned.

Comprehensive laboratory tests of Galv-Welded joints also show that the new galvanizing is strictly a continuous layer with no holes or fissures therein, and is of equally good corrosion-resisting quality as the original zinc layer. During these tests it was found impossible to peel or pry the galvanized coating (Galv-Weld) from the foundation metal, nor could it be removed by abrasion employing a stiff steel brush. The coating would yield only to a cutting operation. Photomicrographs of the coating structure are shown in Fig. 1.

The Galv-Weld process was originally developed by the Artkraft Sign

FIG. 2—Skips and burnt galvanized areas on ammunition boxes are salvaged with Galv-Weld alloy which is much more economical than stripping and then re-hot dipping.

Co., Lima, Ohio, and prior to the war was used as a secret technique. It has since been released by Artkraft for the benefit of the shipbuilding and allied industries in wartime. A free license is being granted on all government work by Galv-Weld, Inc., Dayton, Ohio, which holds the patent on the process. Although it will not be available to all manufacturers until after the war, the peace time uses are numerous since every fabricator of galvanized structures will be able to offer a rust proof weld.

Applications in Shipbuilding

In the shipbuilding industry, generally speaking Galv-Weld alloy is used for re-galvanizing welded seams and pipe joints. In some extreme cases where the structure is too large for hot-dip galvanizing tanks, this alloy is used to galvanize the entire structure. One Cleveland builder of submarine chasers, for example, has employed this method to protect I-beam engine mountings against salt water corrosion.

Other applications in the shipbuilding industry were uncovered by a customer use survey conducted in 1943. A few of these uses are: repairing damaged areas of cadmium plated pieces; filling pin holes in castings; coating of sinks, steam tables, bakery proofers and sanitary drains; fuel and water tanks; re-galvanizing bolt and screw holes and repairing doors and hatches.

A typical example of the application of this process is a job in a large Philadelphia shipyard. A weld on the inside of a large tube had to be made corrosion proof. In applying the process about 12 in. of the weld was brought up to heat with a heating torch from the outside. Heating was then carried on slowly around the tube. A man working inside the tube applied Galv-Weld, brushing it on to cover the weld, and following closely behind the heating torch. About 40 ft. of weld was covered in 20 min. The action of the Galv-Weld stick was used for temperature control. Since it was melted by contact with the heated weld, this worked out well, for when the weld was too cold the stick would not melt. When the weld was too hot the alloy drossed and could not be spread easily until the plate cooled. By watching these conditions, the plater could direct the heater as to the proper heating time, until the heater was able to judge for himself.

Fig. 2 shows Galv-Weld being applied to seams on galvanized 14-gage ammunition boxes made in the Artkraft Sign Co.

. . . Forecasting Tool and Ga

By SERGIUS D. BROOTSKOOS
Mechanical Engineer
Washington, D. C.

° ° °

THE preceding article illustrated that certain rules blended with personal experiences when applied to the problem of tool purchases can accurately determine the quantities of tools that must be held at various points in the plant in order to assure continuous production. In the use of gages the reserves which are indispensable for continuous production of interchangeable parts in any mass production manufacturing plant can be divided into three groups:

A. **Master Gages,** for checking accuracy of all gages in use, as well as of those delivered by the suppliers

B. **Production Gages,** for measuring the parts in production; these gages are usually arranged in sets when delivered to the individual machine operators for measuring the parts at various stages of machining

C. **Inspection Gages,** for checking semi-finished and finished parts before they are transferred to other machines for a consecutive operation or to finished parts bins. These gages are also arranged in sets when sent to individual inspectors.

Production and inspection gages are periodically checked for their accuracy. Many plants have a standing rule that all gages must be replaced either at regular time intervals or after a run of a predetermined number of parts. The replaced gages are carefully re-checked with the help of master gages, and those found in good shape or which have been properly adjusted (in case of adjustable gages) are returned to the gage reserves for future use. The worn out gages are either sent to the salvage department of the plant for hard chromium plating and regrinding or are scrapped altogether. In addition to periodical checkings of all gages in use, many plants employ gage checkers whose duty it is to check all gages in the shop and immediately replace all defective ones.

In order to reduce their investments in gage measuring instruments and in master gages, many plants keep all their gage checking facilities and reserves of gages at a gage store room attached to the office of the chief inspector. This arrangement places the responsibility for interchangeability of all products squarely upon the inspection department of the plant. Furthermore, this arrangement helps to segregate all gages of identical dimensions and limits, irrespective of the parts in the production of which they are used. This results in reducing the reserves of gages in the plant and permits the ordering of gages in larger quantities and at advantageous prices. The distribution of the gages in the plant is illustrated by Fig. 4.

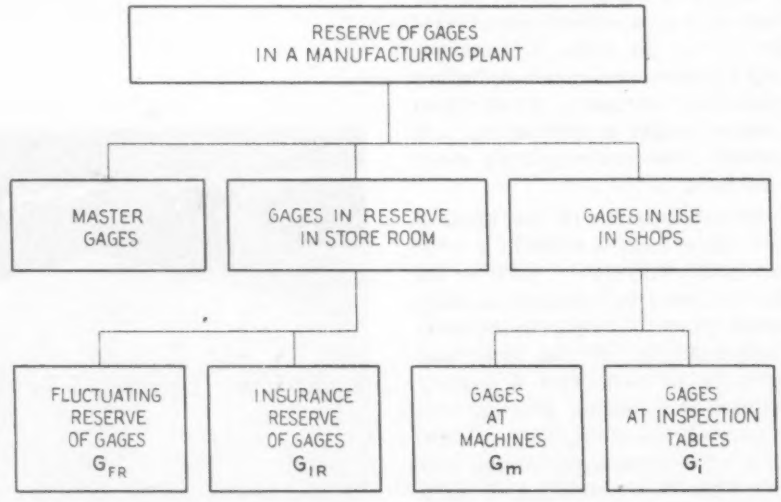

FIG. 4—The distribution of gages in the store room together with gages in use in the shops.

Gages in Use

The number of gages in use at the machines depends on the number of the operators attending these machines. Each machine operator must have a set of production gages irrespective of whether he is attending one or more machines. This number of gages can be expressed by the formula:

$$G_w = \frac{m}{e} \qquad (25)$$

where

G_w = Number of production gage sets at the machines for a particular operation

m = Number of machines performing a particular operation

e = Number of machines attended by one machine operator.

This number lies within the following limits:

$$1 < e \leqq m$$

Parts finished in one machine are usually inspected before they are passed on for the consecutive machining operation or to the bins for finished parts. The number of inspection tables and inspection gage sets depends on the output of the particular machines, and may be expressed by the following formula:

$$G_i = \frac{m}{f} \qquad (26)$$

where

G_i = Number of inspection gage sets at the inspection tables

f = Coefficient, the value of which depends on the number of parts produced by the machines, and which value is within the limits:

$$0 < f \leqq m$$

The total number of gages in use in the shop is then:

$$G_u = G_w + G_i \qquad (27$$

Gage Requirements . . .

. . . This concluding section of a two-part discussion outlines the procedure that should be followed when using the author's formulas in setting up gage purchases. An example shows how the rules of tool and gage procurement are applied to a broaching operation in which the number of broaches in use and those held in reserve are accurately determined.

where

G_u = Number of gages in use in the shop.

Gages in Reserve

When carefully handled, the useful life of gages is long. Therefore, in case of a relatively small production program the number of gages at work in the shop G_u practically determines the number of gages to be procured. In case of a large production program, the number of gages used in the shop serves to determine the adequate sizes of the fluctuating and insurance reserves of gages which must be held in the gage store room and which insure uninterrupted production of the plant. In the following discussion we shall exclude all adjustable gages since their useful life may be considered as indefinite for all practical purposes.

For determining the sizes of the fluctuating and insurance reserves of gages in the gage store room of the plant, let us assume that at the periodical check-ups of the shop gages some are missing and others are worn out and are therefore sent to the salvaging department or scrapped altogether, and that these losses amount in general to l per cent. The number of re-checked gages which can be returned to the gage store room then equals:

$$G_u\left(1 - \frac{l}{100}\right)$$

Let us furthermore assume that the number of individual gages which are brought by the gage checkers for exchange amounts also to l per cent of the total number of gages in the shop. The minimum number of replacement gages which must be held in the gage store room for supplementing the missing gages and for exchanging the defective ones is then:

$$G_u \frac{l}{100} + G_u \frac{l}{100} = 0.02\, G_u l$$

These replacement gages are only a part of the fluctuating reserve of gages in the gage store room. When the average delivery time for new gages in terms of re-check periods is known, the minimum size of this fluctuating reserve of gages can be expressed by the formula:

$$G_{FR} = 0.02\, G_u lz \qquad (28)$$

where

G_{FR} = Minimum fluctuating reserve of gages in the gage store room

Z = Number of re-check periods during the time required for ordering and receiving new gages.

The size of the insurance reserve of gages can be found by using the same method which was described for finding the insurance reserve of expendable tools (see first part of article). Let us assume that the deliveries of the gages are delayed and that a breakage epidemic of gages occurs. In such a case the fluctuating reserve of gages must be of the size:

$$0.02\, G_u lzcd$$

where

c = Coefficient larger than unity ($c > 1$) to take care of breakage epidemics of gages in the shop

d = Coefficient larger than unity ($d > 1$) to take care of the delays in the delivery of gages by the gage makers.

The insurance reserve of gages in the gage store room then equals:

$$G_{IR} = 0.02\, G_u lzcd - 0.02\, G_u lz$$
$$= 0.02\, G_u lz\,(cd - 1) \qquad (29)$$

where

G_{IR} = Insurance reserve of gages in the store room.

o o o

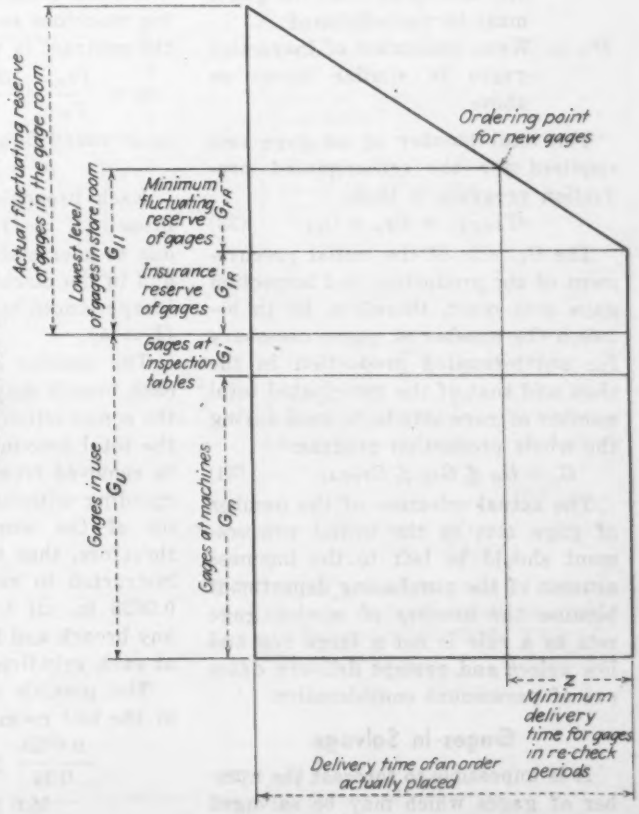

FIG. 5—The classification of gages in a plant illustrating the fluctuating reserve, and ordering point for new gages.

o o o

The lowest level of a stock of gages of one type, size and same limits at the time when a purchase requisition must be issued to the purchasing department is then:

$$G_{ll} = G_{FR} + G_{IR} = 0.02\,G_u\,l_z + 0.02\,G_u\,l_z\,(cd - 1) = 0.02\,lzcd \qquad (30)$$

where

G_{ll} = Number of particular gages in reserve at which level it is necessary to issue a purchase requisition to the purchasing department.

The total requirements of production and inspection gage sets for a production program depend on the number of parts to be produced and on the wear resistance of the gages. Their number, however, must be in multiples of the number of the machine operators and inspectors using them, as follows:

$$G_{TW} = \frac{P_t}{W_w} \qquad (31)$$

$$G_{TI} = \frac{P_t}{W_i} \qquad (32)$$

where

G_{TW} = Total number of production gage sets for a particular operation

G_{TI} = Total number of inspection sets

P_t = Total output of parts in the contemplated production program

W_w = Wear resistance of production gages in terms of the number of parts which may be properly measured until the gages must be reconditioned

W_i = Wear resistance of inspection gages in similar terms as above.

The total number of all gage sets required for the contemplated production program is then:

$$G_{TOTAL} = G_{Tw} + G_{TI} \qquad (33)$$

The G_{ID} size of the initial procurement of the production and inspection gage sets must, therefore, be in between the number of gages necessary for uninterrupted production in the shop and that of the anticipated total number of gage sets to be used during the whole production program:

$$G_u + G_{ll} \leqq G_{ID} \leqq G_{TOTAL} \qquad (34)$$

The actual selection of the number of gage sets in the initial procurement should be left to the business acumen of the purchasing department because the number of needed gage sets as a rule is not a large one and low prices and prompt delivery dates are of paramount consideration.

Gages in Salvage

It is impossible to forecast the number of gages which may be salvaged by chromium plating and regrinding to size. The salvaged gages should therefore be considered as pure savings and they should be deducted from the regular current requisitions.

Table II gives a summary of formulas which are necessary for determining the gage requirements of a manufacturing plant. It also denotes such information and data which are indispensable for solving these formulas. The classification of gages in a manufacturing plant is graphically presented in Fig. 5.

Example

As an example of the application of the formulas presented, let us assume that a plant has a contract for 500,000 parts to be supplied in 10 months. The machining of these parts involves a broaching operation. In calculating the procurement requirements of the plant in broaches, as well as in gages, let us use the same symbols and methods as in the text:

P = Monthly output of contracted parts = 50,000 parts

T_m = Actual working time, in hours per month, of machines in the plant

t_m = Actual broaching time = 3 min. or 0.05 hr.

m = Number of broaching machines to be used.

The plant is working with two shifts, 10 hr. each, 26 days per month and at 75 per cent efficiency:

$$T_m = 0.75 \times 2 \times 10 \times 26 = 390 \text{ hr.}$$

On this basis the number of broaching machines needed for carrying out the contract is (Formula 1.):

$$m = \frac{Pt_m}{T_m} = \frac{50{,}000 \times 0.05}{390} = 6.4$$

or in round figures:

$$m = 7 \text{ machines.}$$

Each broaching machine uses one broach ($K = 1$). The loss of broaches due to poor materials in the broaches and in the machined parts and due to inexperienced help is about 5 per cent ($l = 5$).

The number of grindings g which each broach may undergo depends on the construction of the broach and on the total amount of metal which can be removed from its cutting edges by grinding without impairing the quality of the work. Let us assume, therefore, that the shop tool room is instructed to remove not more than 0.0625 in. all told from the face of any broach and from 0.004 to 0.010 in. at each grinding.

The possible number of grindings in the tool room is then:

$$\frac{0.0625}{0.04} \geqq g \geqq \frac{0.0625}{0.010}$$

$$15.6 \geqq g \geqq 6.25$$

Let us accept that the allowed number of grindings is:

$$g = 9 \text{ grindings}$$

Furthermore, let us assume that the broaches are changed at the start of each working shift, i.e., after 10 hr. of continuous work:

$$t_w = 10 \text{ hr.}$$

The monthly requirements of broaches are then (Formula 9):

$$E_m = \frac{Pt_m K}{t_w\left(g+1\right)\left(1-\frac{e}{100}\right)} = \frac{50{,}000 \times 0.05 \times 1}{10\left(9+1\right)\left(1-\frac{5}{100}\right)}$$

$$= 26.3 \text{ broaches}$$

or in round figures:

$$E_m = 26 \text{ broaches}$$

The working cycle of a broach from the time it leaves the crib and until it returns for regrinding is:

$$t_c = t_w + 2 = 10 + 2 = 12 \text{ hr.}$$

We will assume that the broaches are held in the grinding section of the tool room for a complete working day:

$$t_g = 20 \text{ hr.}$$

The average time for an emergency requisition of the tool room to materialize will be:

$$t_e = 5 \text{ hr.}$$

The values of the coefficients x, y and z are then (Formulas 13, 14 and 15):

$$x = \frac{t_e}{T_m}\left(g+1\right)\left(1-\frac{l}{100}\right) = \frac{12}{390}\left(9+1\right)\left(1-\frac{5}{100}\right) = 0.292$$

$$y = \frac{t_g}{T_m}\left(g+1\right)\left(1-\frac{l}{100}\right) = \frac{20}{390}\left(9+1\right)\left(1-\frac{5}{100}\right) = 0.487$$

$$z = \frac{t_e}{T_m}\left(g+1\right)\left(1-\frac{l}{100}\right) = \frac{5}{390}\left(9+1\right)\left(1-\frac{5}{100}\right) = 0.122$$

Number of broaches at work in the machines (Formula 2):

$$E_w = mk = 7 \times 1 = 7 \text{ broaches}$$

Minimum number of broaches to be held in the crib section of the tool room (Formula 10):

$$E_c = xE_m = 0.292 \times 26 = 6.592$$

or in round figures—$Ec = 7$ broaches.

Maximum number of broaches to be held in the grinding section of the tool room (Formula 11):

$$E_g = yE_m = 0.487 \times 26 = 12.662$$

or in round figures—$Eg = 12$ broaches.

The number of broaches in use which must be held in the tool room at any time in order to assure uninter-

rupted production is then (Formula 6):

$$E_m = E_w + E_e + E_g = 7 + 7 + 12 = 26 \text{ broaches}$$

Let us assume that new broaches are delivered to the tool room biweekly which covers half monthly requirements of the shop in broaches. The fluctuating reserve of broaches in the tool room may then be considered equal to (Formula 5):

$$E_{FR} = AE_m = \tfrac{1}{2}E_m = 0.5 \times 26 = 13 \text{ broaches}$$

The minimum number of usable broaches in this fluctuating reserve when an emergency requisition must be issued is (Formula 12):

$$E_e = zE_m = 0.122 \times 26 = 3.172 \approx 3 \text{ broaches}$$

The maximum number of usable broaches to be held in the shop and the tool room is:

$$E_{max} = E_m + E_{FR} = 26 + 13 = 39 \text{ broaches}$$

and, accordingly, the lowest level of broaches in the shop when an emergency requisition for them must be issued is then (Formula 8):

$$E_{II} = E_m + E_e = 26 + 3 = 29 \text{ broaches}$$

The number of broaches to be held in the main store room depends on the number of identical broaches required by other shops of the plant, on the delivery time usually granted by the broach manufacturers and on the time it takes the purchasing department to receive a requisition to issue invitations for bids, to receive the bids and to place the order. Let us assume that only one shop uses broaches of the above type and that it takes at least 2.5 months for a requisition to materialize. This is represented as:

$$T_d = 2.5 \text{ months}$$

The minimum size of the fluctuating reserve of broaches in the main store room of the plant should be (Formula 16):

$$(ET)_{MFR} = E_m T_d = 26 \times 2.5 = 65 \text{ broaches}$$

The insurance reserve of broaches is calculated on the following basis: first, that the demand for broaches during breakage epidemics increases by 20 per cent ($c = 1.2$), and, second, that the delivery of ordered broaches may be delayed about 1.5 times ($d = 1.5$). The size of the insurance reserve of broaches which should be kept in the main store room of the plant is then (Formula 19):

$$(ET)_{IR} = E_m T_d\,(cd-1) = 26 \times 2.5 \times (1.2 \times 1.5 - 1) = 65 \times 0.8 = 52 \text{ broaches}$$

The lowest level of the stock of broaches in the main store room of the plant when a requisition for additional broaches must be issued to the purchasing department is equal to (Formula 18):

$$(ET)_{II} = (ET)_{IR} + (ET)_{mFR} = 52 + 65 = 117 \text{ broaches}$$

The minimum size of the initial procurement of broaches at the start of the production program is then (Formula 21):

$$(ET)_{1.0} \geqq (1 + a + cdT_d)\,E_m$$
$$(1 + a + cdT_d) = [1 + 0.5 + (1.2 \times 1.5 \times 2.5)] = 6;$$
$$E_m = 26$$
$$(ET)_{1.0} \geqq 156 \text{ broaches}$$

The total number of broaches needed for the contemplated production program (Formula 22):

$$E_T = E_m \times T_p = 26 \times 10 = 260 \text{ broaches}$$

The maximum value of the coefficient b in the formula 17 for calculating the procurement requirements for the fluctuating reserve of broaches in

TABLE II

Formulas and Data Necessary for Determining the Number of Gages for Checking Individual Machined Parts

Description	Mathematical formulas		Necessary Data
	No.	Expression	
Number of working gages	25	$G_w = \frac{m}{e}$	e = Number of machines attended by one operator
Number of inspection gages	26	$G_i = \frac{m}{f}$	f = Coefficient which depends on the output of the machines
Number of all gages in use	27	$G_u = G_w + G_i$	
Number of gages in the fluctuating reserve	28	$G_{FR} = 0.02\,G_u lz$	l = Losses of gages in the shop, in per cents z = Time needed for a requisition to materialize, in re-check periods
Number of gages in the insurance reserve	29	$G_{IR} = 0.02\,G_u\,(cd - 1)$	c = Coefficient for "breakage epidemics" d = Coefficient for delivery delays
Lowest level of gages in the gage store room when a new procurement must be made	30	$G_{II} = G_{FR} + G_{IR}$	
Total number of working gages needed for the planned production	31	$G_{Tw} = \frac{P_t}{W_w}$	W_w = Wear resistance of working gages, in number of measured pieces
Total number of inspection gages needed for the planned production	32	$G_{TI} = \frac{P_t}{W_i}$	W_i = Wear resistance of inspection gages, in number of measured pieces
Total number of all gages required for the planned production	33	$G_T = G_{Tw} + G_{TI}$	
Minimum number of gages in the initial procurement	34	$G_{ID} \geqq G_u + G_{II}$	

the main store room of the plant is (Formula 23):

$$b \leqq \frac{1}{T_d}\,[T_p - (1 + a + cdT_d)]$$

$$b \leqq \frac{1}{2.5}\,(10 - 6) \leqq 1.6$$

The last three figures mark the limits within which the purchasing department may plan its procurement policy for securing the necessary broaches at advantageous prices and delivery terms.

We shall now ascertain the number of gages required for gaging the broaching work. The number of gage sets used by the operators at the machines, on the assumption that each operator attends one machine or the coefficient: $e = 1$ is (Formula 25):

$$G_w = \frac{m}{e} = \frac{7}{1} = 7 \text{ gages}$$

The daily production of parts is:

50,000 : 26 ≈ 2000 parts approx.

This number can easily be handled by one inspector, and thus with the coefficient: $f = 7$ (Formula 26):

$$G_i = \frac{m}{\mathrm{d}} = \frac{7}{7} = 1 \text{ gage}$$

The number of all gages in use is then (Formula 27):

$$G_u = G_w + G_I = 7 + 1 = 8 \text{ gages}$$

Let us assume that the gages are re-checked every week and that the losses amount to 1 per cent ($l = 1$); let us furthermore assume that the shop checkers on their tours in the shop disclose about 1 per cent ($l = 1$) of defective gages. Now let us suppose that the plant management has learned from experience that it takes about 2½ months for a requisition for gages to materialize, or in terms of re-check periods $z \approx 12$ periods.

The minimum fluctuating reserve of gages is then (Formula 28):

$$G_{FR} = 0.02\, G_u lz = 0.02 \times 8 \times 1 \times 12 = 1.92$$

or in round figures $G_{FR} = 2$ gages.

Under conditions where the delivery of gages may be delayed, say by 50 per cent, and a breakage epidemic may increase the demand for new gages, say by 20 per cent, the insurance reserve must then be of the size (Formula 29):

$$G_{IR} = 0.02\, G_u lz\,(cd - 1) = 0.02 \times 8 \times 1 \times 12 \times (1.2 \times 1.5 - 1) = 1.536$$

or in round figures $G_{IR} = 2$ gages.

The lowest level of gages in the gage store room when a new requisition to the purchasing department must be issued (Formula 30):

$$G_{II} = G_{FR} + G_{IR} = 2 + 2 = 4 \text{ gages}$$

Let us assume that a production gage will withstand say 25,000 handlings and an inspection gage, 50,000 handlings before they must be reconditioned or scrapped altogether. Since the contemplated production of parts is:

$$P_t = 500{,}000 \text{ parts}$$

the total number of production and inspection gage sets for the required output of parts is (Formulas 31 and 32):

or in multiples of seven:

$$G_{Tw} = \frac{P_t}{W_w} = \frac{500{,}000}{25{,}000} = 20$$

$$G_{Tw} = 21 \text{ gages}$$

$$G_{TI} = \frac{P_t}{W_i} = \frac{500{,}000}{50{,}000} = 10 \text{ gages}$$

The total number of gage sets which will be needed is then (Formula 33):

$$G_{TOTAL} = G_{Tw} + G_{TI} = 21 + 10 = 31 \text{ gages}$$

The initial procurement must be of the size (Formula 34):

$$G_u + G_{II} \leqq G_{1.0} \leqq G_{TOTAL}$$

$$G_u + G_{II} = 8 + 4 = 12$$

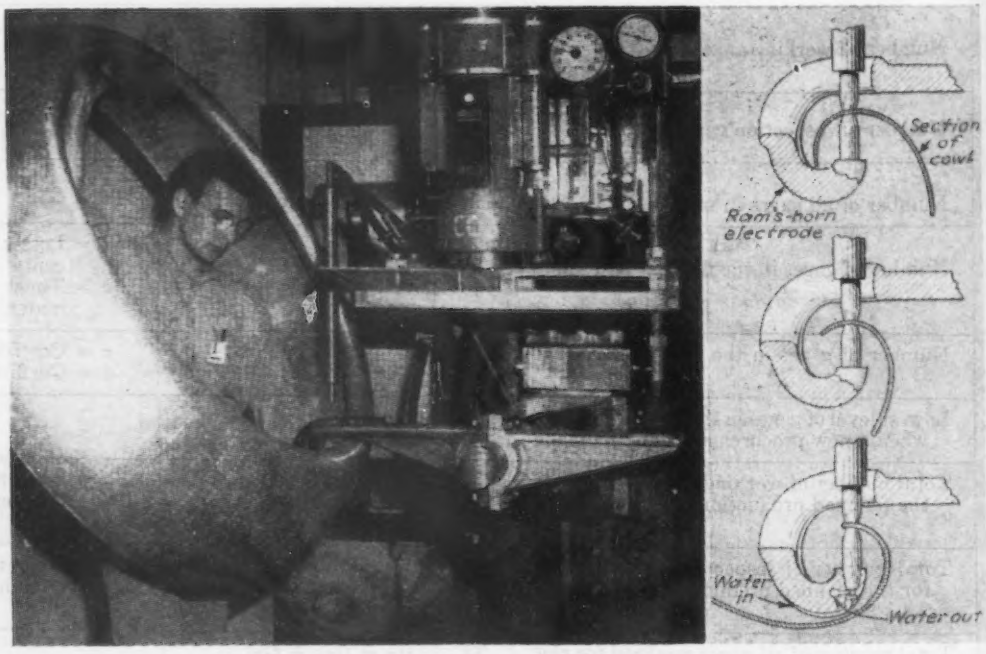
$$12 \leqq G_{1.0} \leqq 31$$

The number of required gage sets is not very large, hence the purchasing department must be given full freedom to order either a part or the total number of the needed gage sets.

Ram's Horn Welds Around Corner

SPECIFICATIONS called for welding reinforcements and joints of an engine cowling made by Miami Division, Consolidated Vultee Aircraft Corp. Most of the welding job was straightforward work, but on the curved inside lip there was no way to do it with standard equipment. The foreman in charge of this work suggested using a "ram's horn" bar, according to the magazine *Wings*. It was tried and is working successfully. Its shape is evident from the accompanying sketches.

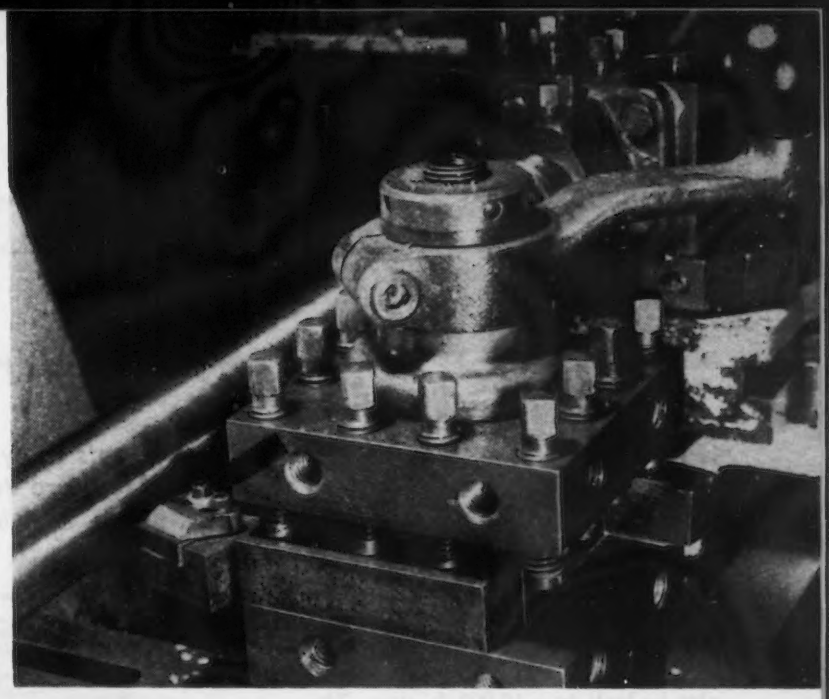
The secret of its success results from the ingenious way in which pressure is applied to the electrodes. If offset electrodes had been used alone, the pressure could not be fully utilized without putting excessive side strains on the welder. Balance arms of the same length are extended to the opposite side. On the upper one is a stud, which can be adjusted to contact a pad on the lower just as the electrodes meet. Thus no side strains are transmitted to the welding-machine head, and pressure at the electrodes can be controlled as though they were directly beneath the center of the head.

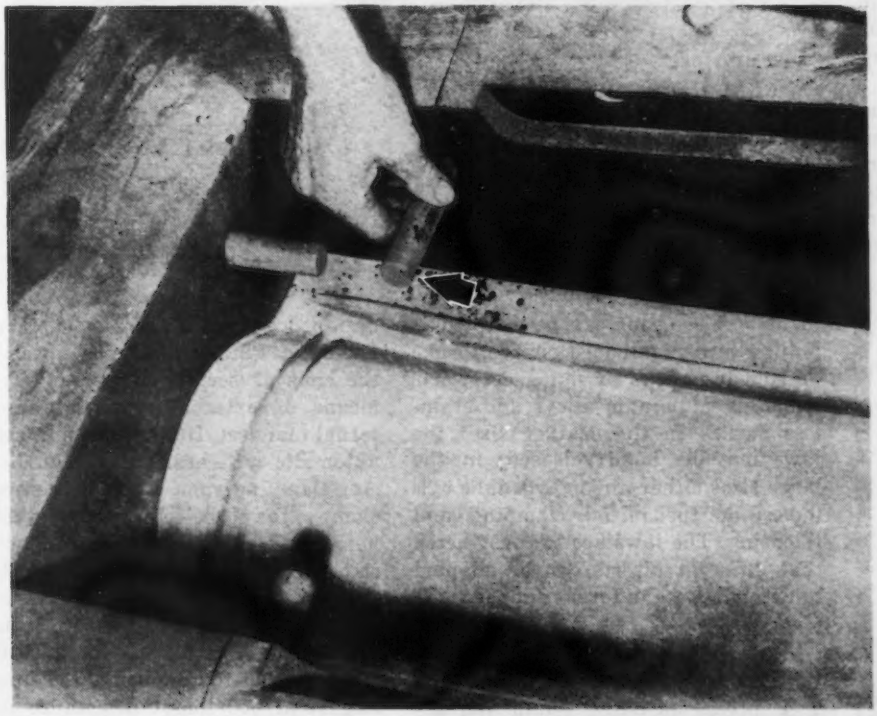


WELDING curved lip on inside of engine cowling. On the left is the welding electrode, on the right the pressure-balance arm. This combination assures perfect control of pressure on electrodes. Cross-sections of the cowl in the sketches at right show how easy it is for the operator to weld all around the curved lip when using this "ram's horn" fitting on the welder.

Production Short Cuts

. . . Employees of North American Aviation, Inc., Inglewood, Cal., and Douglas Aircraft, Santa Monica, Cal., have received suggestion awards for the man and material saving improvements shown here.





o o o

ABOVE

REPLACING the old method of brazing carbide cutting tools to the holder block, this combination clamp and chip breaker, fitted with three set screws, holds the tools to the holder block. A shock shim also is provided. The holder can be used many times longer than was possible with brazing. S. Schimel of the machine shop at Inglewood division, North American Aviation, Inc., devised the clamp.

o o o

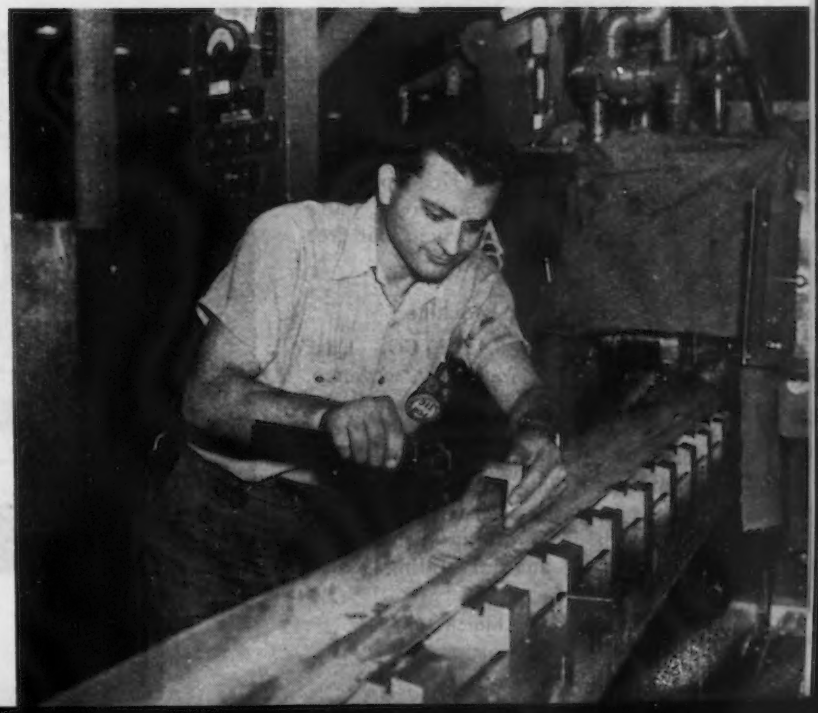
ABOVE

USE of steel chill cores instead of sand saves 5 in. of steel welding rod in each core, as well as the time of drilling the sand cores for lifting pins. The welding rod was formerly used for strengthening the sand cores. The new steel cores are coated with a mixture of clay and graphite and are easily loosened and extracted by a turn of the protruding square shank. They were suggested by Colin D. Matier, molder in the foundry of Inglewood division, North American Aviation, Inc.

o o o

RIGHT

A NEW method of using Kirksite tooling instead of steel to mill spar caps, developed by Ivan J. David, is used at Douglas Aircraft. Blocks of Kirksite are cast and bolted to the bed of the spar cap mills, machined to the proper shape and beveled to hold the spar cap in position for machining. Kirksite tends to dampen out vibrations, resulting in a smoother cut. Obsolete tools can be remelted.

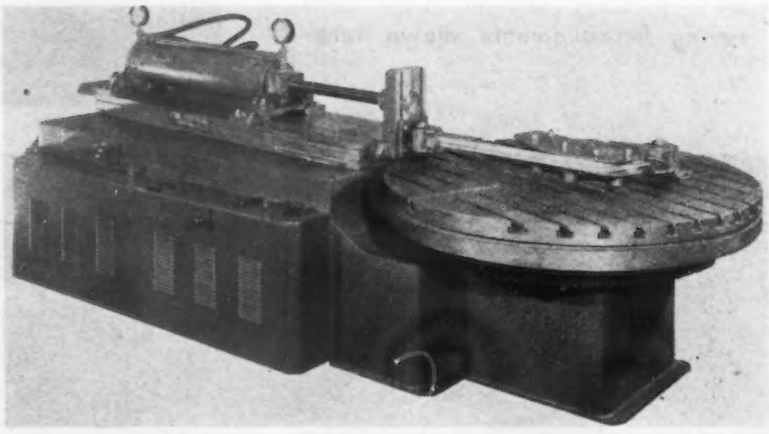


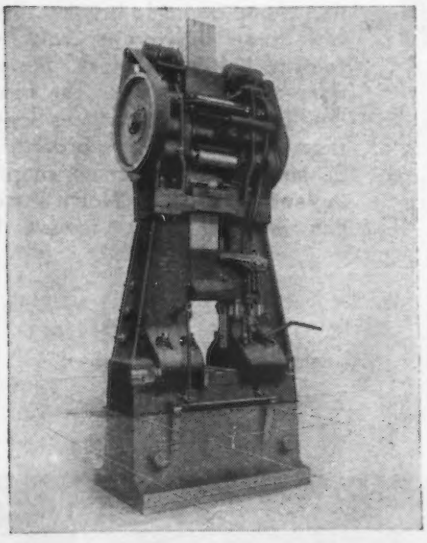
New Equipment . . .

Presses

. . . New developments in hydraulic and hand presses and related sheet metal machinery are described and illustrated in the following pages.

A 7500-lb. four-roll board drop hammer with self-contained motor drive has been brought out by the *Erie Foundry Co.*, Erie, Pa. It can also be built in a 10,000-lb. size. The motors are carried on top of the hammer, thereby avoiding overhanging mountings. The small sheave is above the large one. A gear reduction is placed between the pulley shaft and the roll shafts. While the rolls are free to move in and out to grip and release the board, the center-to-center distances of the gears and pinion do not vary, so that standard involute





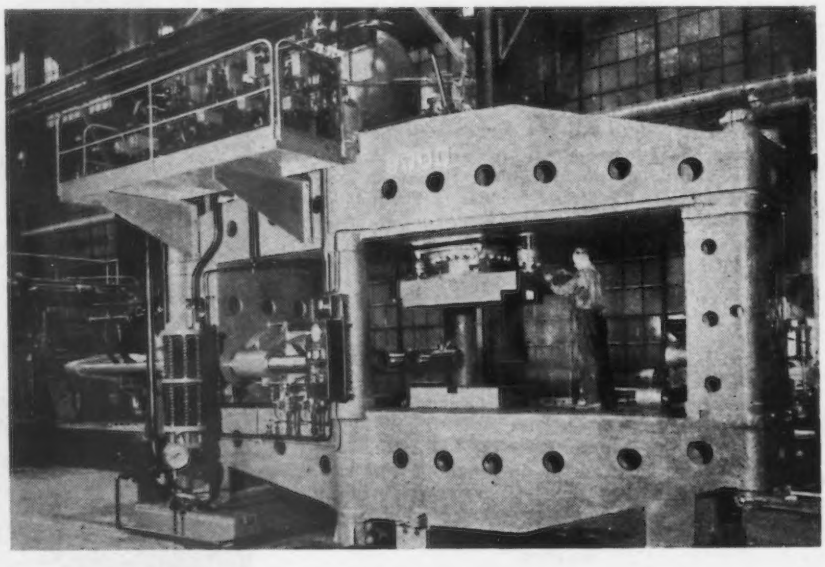
tooth forms can be used. The speed of the pulleys is great enough to provide considerable flywheel effect. The unit uses the patented Erie construction, the rolls being carried in pairs for equalizing frames which float free on the eccentrics.

Stretching Machine

THE CYRIL BATH CO., East 70th and Machinery Avenue, Cleveland 8, has developed a semi-standard stretch head for use in connection with its rotary stretch forming presses. The casing of the head is made in various sizes and may be fitted with jaws giving either two, three or four angular sliding movements. The heads can be adapted to pulling either extruded shapes, brake or rolled sections or flat sheet work, including aluminum alloys and stainless steel. In the smaller sizes the jaws may be hand released; in the large sizes either air or hydraulic cylinders do the initial clamping and releasing. The jaws are so constructed that different inserts can be adapted to accommodate different shapes.

Upsetting Press

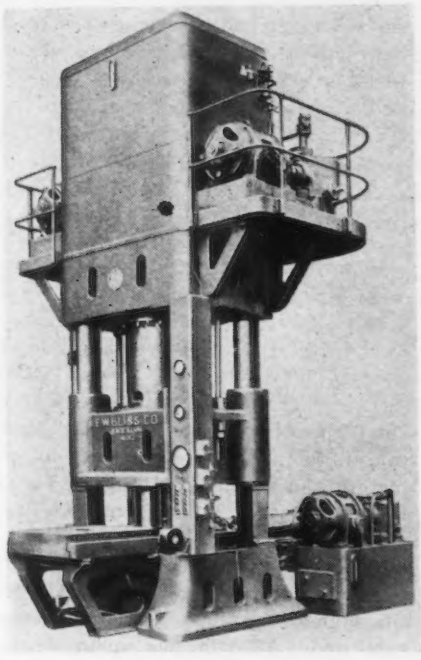
A 600-900-ton hydraulic upsetting press, including pump and accumulator operating system, has been designed by *R. D. Wood Co.*, Wood Building, Philadelphia, for upsetting the ends of seamless steel tubing by means of external dies and an internal mandrel. It operates on a semi-automatic cycle basis. The 28 in. diameter clamping ram, with 12 in. stroke, clamps the tube before the guided horizontal ram can start its work stroke. When the stroke is completed, the 23 x 22 in. diameter horizonal ram strips from the tube before clamp ram pressure is dissipated. Vertical ram has 900 ton capacity, the upsetting ram, 600 tons. Resistance post is provided with adequate adjustment.



An air cylinder is arranged to move a space block into position when the tube is turned around for upsetting the second end. An auxiliary 11 in. diameter horizontal ram stripper strips the mandrel from the tube.

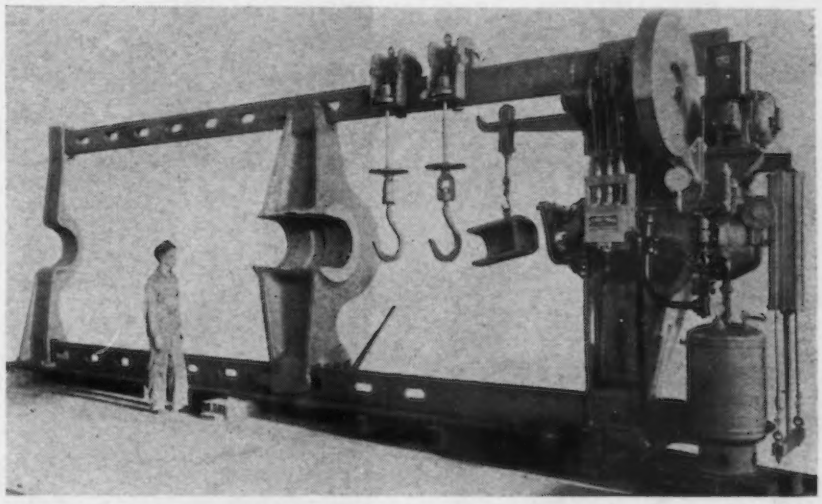
Forging Press

THE 1000-ton self-contained hydraulic forging press built by the *E. W. Bliss Co.*, 53rd Street and 2nd Avenue, Brooklyn 32, N. Y., is equipped with a 35-ton ejector and a sliding die table. It is interlocked by means of an electrical control so that the press, die slide and ejector operations can only occur when the different actions are in their proper positions. The 150-hp. pumping unit permits quick advance speed of 750 in. per min. and return speed of 725 in., with a pressing speed of 37 in. per min. Four methods of operation are provided for the main slide: Semi-automatic cyclic operation; full automatic operation; joggling control by means of a drum type switch; and inching control, permitting small increments of approach.



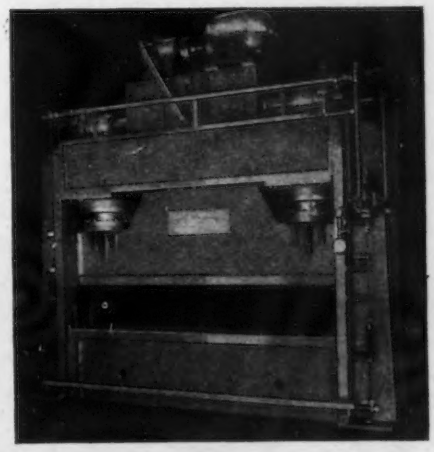
Hydraulic Wheel Press

A SELF-CONTAINED hydraulic wheel press with unique pneumatic pullback, for use in railroad repair shops, machine shops and general industrial work, is being marketed by the *R. D. Wood Co.*, Wood Building, Philadelphia. Openings of 10 in. radius in the resistance post and the end post accommodate the work. The resistance post operates on bearing equipped rollers on the machined face of the base plate. The pump is of the vertical, triplex, two pressure type, having two high pressure and one low pressure plungers, actuated by three eccentrics. The press can be installed flush with the floor. A pneumatic pullback device does away with the necessity of providing a pit to accommodate counterweights.



Forming Press

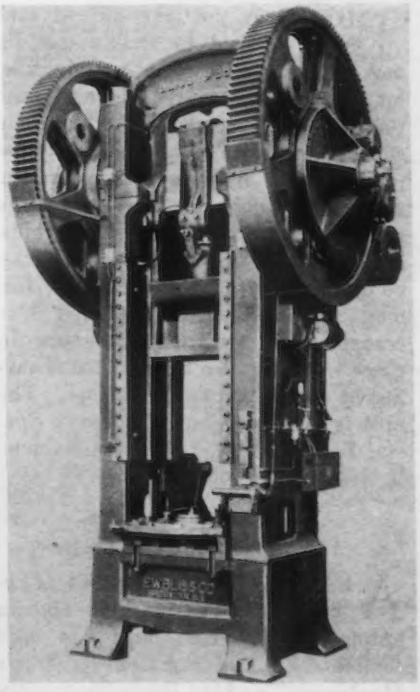
A NEWLY designed, heavily built unit of the closed housing type suited for straightening of armor plate and long lengths of shafting and rolled shapes has been brought out by the *Beatty Machine & Mfg. Co.*, Hammond, Ind. It has a maximum capacity of 400 tons, with an 8 in. stroke. Advance speed is 330, pressing speed 20 and return speed 385 in. per min. Operating pressure is 2000 lb. per sq. in. The units are built in a range of sizes from 100 to 600 tons.

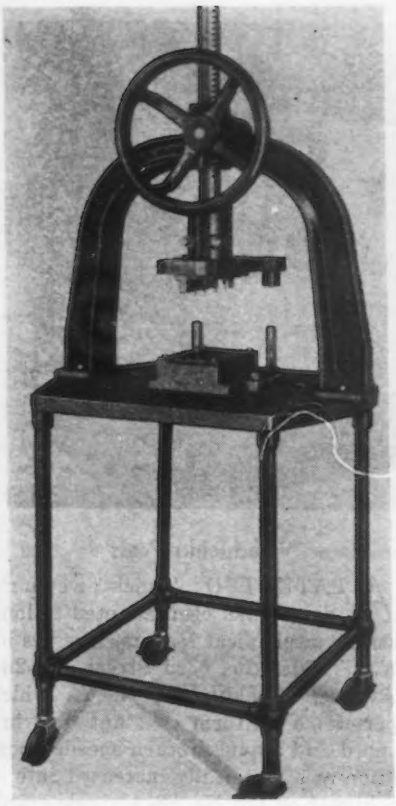


The company has also put on the market a 350 ton integrally built hydraulic press for joggling plates and shapes, heavy forming and bending in shipyards, car and tank shops. This unit is arranged for hand or foot control of the ram movement and is built in capacities from 5 to 350 tons.

Reducing Press

A PATENTED "quick return drive" has been adapted to long stroke mechanical reducing presses by *E. W. Bliss Co.*, 53rd Street and 2nd Avenue, Brooklyn 32, N. Y., which permits a uniform constant drawing speed and a quick return speed. Operation at a materially increased rate is achieved on the No. 88-A single-crank single action press without any increase in the drawing speed. Twin driving gears divide the torsional load between two slides and slabs of the shaft. The machine is of four-piece steel tie-rod frame construction with double gearing and operates at 14 strokes per min. It is equipped with a multiple flywheel type disk, air friction clutch and brake with push button control. For maximum production a six station dial feed is employed.





Die Set Machine

THE Lacey portable die set machine is said to enable the die maker to complete a die set right at his bench and assures faster, truer punch-to-die alinement. With the die shoe clamped to the table and the punch holder fixed in position in the ram, the punch can be removed as often as needed without disturbing alinement. A "one-man" press, it can be operated with one hand under full manual and visual control, and it is transportable with the die shoe in place. It may also be used for shearing in certain types of punches. The unit is distributed by the *Moore Special Tool Co., Inc.*, 740 Union Avenue, Bridgeport 7, Conn.

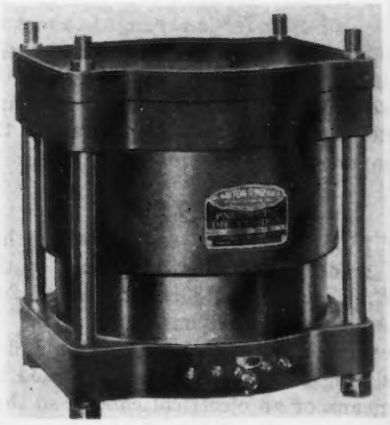
Hydraulic Extrusion Press

A LABORATORY type 12-ton hydraulic extrusion press and an automatic wire feed unit has been combined in one machine by *Moslo Machinery Co.*, 2443 Prospect Avenue, Cleveland. While designed primarily for the extrusion of welding rods, the press may be had with dies for extruding powdered metals, carbon and certain plastics. Pressure of 10,000 lb. per sq. in. is achieved, which, combined with the automatic wire feeding, makes the machine suitable for small scale production of welding electrodes. A separate cylinder is used for slugging. The extrusion die head

is at a 45 deg. angle. Deflection in the wire guide is said to be minimized by this design, due to the fact that the flux is forced in a direction more in line with the wire guide.

Die Cushion

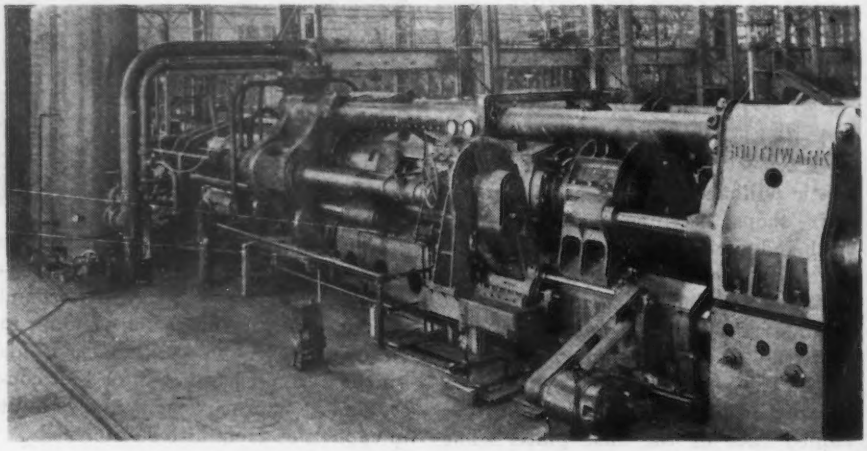
FOR direct mounting to the bolster plate of practically any power punch press, the Model CB pneumatic die cushion has been developed by the *Dayton Rogers Mfg. Co.*, 2835 12th Avenue South, Minneapolis. A hardened and ground pin pressure pad can be machined and fitted to the individual press bed opening, replacing the springs and rubbers on dies already in use. The units are built in sizes from 6 to 24 in., having a drawing capacity from 2 to 12 in. Ring holding pressures of from 1½ to 23 tons are developed on 100 lb. air line pressure. The company has also designed a hydraulic release mechanism which protects the machine frame and crankshaft of a punch press in the event of overload. The connecting link between crank and slide is made up of



a hydraulic cylinder and piston with integral pump and relief valves. Under overload conditions, the safety relief valves crack at the maximum working pressure of the press, shortening the strap and allowing the crank to go through its cycle without damage to the machine.

Extrusion Press

A 3500-TON extrusion press, designed for both direct and indirect extrusion, has been completed by the Baldwin Southwark Division of the *Baldwin Locomotive Works*, Philadelphia. The press is equipped with a 250-ton hydraulic billet shear, two coarse tooth saws driven by 40-hp. motors and a billet handling device to take the heated billet from the furnace and deposit it in front of the extrusion container. It is of the four-rod type, with forged tension rods 16 in. diameter. The 59-in. diameter ram, under 3200 lb. per sq. in. working pressure, will handle billets up to 24 in. in diameter and up to 36 in. long. Its working stroke is 7 ft. Main ram is rapid traversed to working position under a low pressure of 200 lb. The press is operated from two 500-hp. multiple plunger pumps in connection with a hydro-pneumatic accumulator system.



'Round and 'round it goes

OILGEAR

n this rotary casting
achine Oilgear Fluid
ower solved 4 diffi-
ult design problems.

and where it stops only Oilgear knows!

ONE of the many places in which Oilgear Fluid Power has been applied to solve long-standing power application problems has been on the drives of paper-making machines. Here it has provided the means of closely synchronizing many motions so that the fragile web of paper under manufacture can be handled at much higher speeds without rupture.

Oilgear Fluid Power has supplied the now-it-can-be-done happy ending to many another long story of getting machinery to do the seemingly impossible. Among the many functions it provides are steplessly variable speed control of a moving member . . . traverse and return at different speeds . . . synchronizing of intricate sequences or cycles . . . a combination of straight-line and rotary motions.

It is almost certain you will find a solution to *your* design problem in the versatility of Oilgear Fluid Power and the long experience of Oilgear Engineers with hundreds of companies building machines and mechanisms of widely diversified use. *Now* is the time to find out. The Oilgear Company, 1303 W. Bruce Street, Milwaukee, Wisconsin.

ARE YOU TRYING TO:

1. Apply large forces through long . . . or short . . . strokes at variable speeds?
2. Obtain automatic work cycles, variable speeds in either direction . . . with or without pre-set time dwell?
3. Apply large forces through continuous or intermittent reciprocating cycles at constant or variable velocities?
4. Obtain extremely accurate control of either position or speed of a reciprocating member?
5. Apply accurately variable pressure either static or in motion?
6. Closely synchronize various motions, operations or functions?
7. Apply light . . . or heavy . . . forces at extremely high velocities through either long or short distances of travel?
8. Obtain continuous automatic reversing drives at constant R P M or over a wide range of speed variation?
9. Obtain accurate remote control of speed and direction of rotation, rates of acceleration and/or deceleration?
10. Obtain constant horsepower output through all or part of a speed range?
11. Obtain automatic torque control?
12. Obtain accurately matched speed of various rotating elements?
13. Obtain constant speed output from a variable speed input?
14. Obtain full pre-set automatic control, elimination of problems of shock, vibration, etc.?

You Need Oilgear!

Assembly Line . . . STANLEY H. BRAMS

• The Detroit scene is a wonderland today of facts and fancy, one in which the concrete progress of the times is mingled with events startling in wartime.

DETROIT—The scene in Detroit this March, to borrow from a versifier, has been various. In and out of the public eye, industry has been agitated, intrigued, stimulated and depressed by strike disorders, draft hysteria, technical developments, reconversions, layoffs, hirings, senatorial chest-beating, and plain stupidity.

It has been, to put it gently, a busy fortnight. To wit:

Strike Disorders. The Pratt & Whitney building at Ford's Rouge plant was the scene of slugging of a plant protection man by a worker goon squad engaged in wrecking the office of a labor relations man with whom they had differences. Subsequently the 10 leaders of this curious "demonstration" were discharged and 10 more suspended by the company, with the UAW concurring.

This building has been a troublesome spot for many months. Discipline has gradually evaporated as employes discovered that—until now—the union would back them up in virtually any action they undertook. At Christmas time, for instance, an epidemic of celebratory tie-snipping reached upward from the help to supervision and management; anyone who started off in the building the day before Christmas with a tie lost it. One man lost considerable blood, into the bargain, when he fought to save his tie, failed, and in the process got a good deal of his neck in the path of the shears.

This kind of horseplay, akin to the episode at Continental Motors when a "hotfoot" ignited the greasy overalls of one man and cremated him, is posing a serious problem for many Detroit company officials. A firm management hand is needed, and unless the UAW backs up severe disciplinary action as it has in the 20 Ford cases it will have established beyond doubt what its critics have long maintained —that its end-objective is to disrupt production so completely, war or peace, that it can move in to take charge of the shambles.

Draft Hysteria: Orders from Washington to reconsider occupational deferments led Michigan draft boards to weigh down the postman with 1-A notices early in March, delivered to essential and non-essential men alike. Companies protested and hoped the appeal boards would bear with them. The Automotive Tool and Die Association sharply challenged the statement of state selective service officials that the scarcity of toolmakers was ended, making them fit draft candidates.

The calling up of so many deferred men was expected to be inevitably followed by the induction of at least a fair proportion of them. Companies expected to have to face resultant problems in their engineering rooms as well as in their shops; some said simply that if and when they lost some of the personnel classified 1-A they simply would have to operate in lower gear, because the day of replacements of such top-bracket men has long since passed by.

Technical Developments: Very quietly the war is bringing forth most significant changes not only in products, but in the equipment to fabricate them. Consider, for instance, these three new machine tools which have lately been completed in Detroit:

First, a machine that all but eliminates drill breakage by automatic reversal of the head when chips pile around the flutes.

Second, a machine which shapes gear teeth in a fraction of the time formerly required, and does all teeth around the circumference simultaneously.

Third, a machine which broaches to spherical dimensions.

Reconversion: The Norge Division of Borg-Warner Corp. has resumed production of kitchen gas ranges at Muskegon Heights, Mich., to meet WPB authorizations for civilian goods. This manufacturing is being done on production lines alongside of others producing gun turrets for dive bombers and bottom cowl and other special assemblies for Thunderbolt fighters.

More notable rearrangements were necessary to resume output of tires at Goodyear's Jackson, Mich., plant, which is now in near-capacity volume on casings for essential civilian and military passenger cars and trucks.

Other plants are likewise undertaking jobs akin to their prewar assignments. This leads to the possibility that the return to civilian goods production may not be the abrupt about-face generally expected on Victory Day, but perhaps will have been preceded by a gradual creeping toward this goal in a pre-peace period now being approached.

Layoffs and Hirings: Substantial layoffs are coming to light here and there, beyond others already announced. Olds, in Lansing, has dropped a considerable number of men working on gun jobs which have been cut back. Similar soft spots exist on gun work at Pontiac. In Detroit, Ford has quietly laid off some men since early February.

Hirings, meanwhile, are being made in other plants increasing unspecified aircraft schedules. The overall effect points to what was said here last Dec. 23—that Detroit employment in Michigan dropped 1 per cent in January from December levels, and probably fell slightly in February also.

Ineptitude: The story concerns an officer in one of the services who came to Detroit for certain discussions and, on seeing pictures of some sub-zero cabinets to contain airframe rivets, inquired whether the purpose of such storage was to test the rivets for the high altitudes which they would see in aircraft use. The question assumed grotesque proportions a few minutes later when the officer dropped the remark that he was selected for the work he was doing because of his "technical knowledge."

Senatorial Chest-Beating: Senator Homer Ferguson aroused the ire of his home state's auto industry some days ago when he complained loudly that 70 per cent of auto industry contracts were on a cost-plus basis. The Automotive Council maintains that the proportion was only 25 per cent, and then mostly on types of items on which there was no previous production experience or on which specifications were rapidly changing.

Last week the ebullient senator,

TOOLS FOR
Accurate
THREAD CUTTING
Here you see a small portion of one day's harvest of dies from Pratt & Whitney's Small Tool Division. These round split dies are but one of many types of accurate thread cutting tools we make, including thread-rolling dies.
All over the nation, P&W thread cutting tools of various kinds are turning out top-notch threads . . . rapidly . . . at low cost. Other Pratt & Whitney small tools include cutters, reamers, taps, dies, punches, drills, counterbores, special tools of all kinds. Mechanics everywhere know and like P&W Small Tools . . . precision made by master craftsmen . . . of highest quality uniform steels . . . scientifically heat treated to maintain their keen cutting edges.

who evidently conceived a love for front page ink when he did a capable job of operating a Detroit graft inquiry grand jury, sounded off again over the "wrist slapping" punishment meted out to Army officers involved in the sale of surplus cutting tools by the Air Forces last summer (THE IRON AGE, Sept. 30, 1943, page 66).

In the thirst for stern retribution, senses of proportions have apparently been lost by the good senator and a Detroit newspaper which has sensationalized the incident since it came to light. Else they would have inquired why the heaviest punishment—honorable discharge from the Army—should have been meted out to a second lieutenant who appears to have been a perfect version of an innocent bystander. This shavetail was in charge of the storeroom in which the tools were being kept and inventoried. Certainly no one with an iota of realization of Army processes could think that this second lieutenant had a voice in the actual sale of the surpluses.

Discharge from the Army seems to be a high price to pay for the inadvertence of happening to be on a job on which direction from above was undoubtedly stupid, but otherwise clear of wrongdoing. Let the chest-beaters think along those lines for a while, and their indignation might become more justified.

RESIGNS: *Charles E. Sorenson, vice-president of Ford Motor Co. resigned his post last weekend after 40 years of association with the manufacturing end of the company.*

Magnesium Smelter at Ford to Close

Detroit

• • • **The magnesium** smelter at Ford Motor Co., built by the Defense Plant Corp. in 1942, has been closed down and probably will be held in readiness as a standby plant. The shutdown was ordered by the government in the light of the satisfactory magnesium supply situation today.

The Ford plant, built at a cost of several million dollars, had a capacity upwards of 1,500,000 lb. of magnesium per month. Fires were lighted in it April 20, 1942, and the first magnesium was drawn on May 10 of that year. Since then a total of 94 furnaces have been placed in operation.

The Ford plant was largely experimental at all times, being one of two units planned for operation in this country utilizing the ferrosilicon process. The National Academy of Science was understood to have figured in the developing of details of the process for application at Ford, and River Rouge technicians later made important improvements in the methods.

Simultaneously with the erection of the smelter, the cement plant at River Rouge was converted for burning dolomite limestone ore. The kilns converted for this purpose at the cement plant are, as a result of the smelter's closing, idle at this time.

WPB Advisory Committee

• • • **The WPB Office** of Industry Advisory Committees announced the formation of the Metal Cutting Hack and Band Saw Industry Advisory Committee. William C. Teare, Tools Division, has been appointed the government presiding officer.

Members of the committee are:

H. G. Aldridge, Huther Bros., Rochester, N. Y.; Jacob S. Disston, Henry Disston & Sons Co., Philadelphia; R. F. Ellis, E. C. Atkins & Co., Indianapolis; J. H. Flavell, W. O. Barnes Co., Inc., Detroit; William J. Greene, The L. S. Starrett Co., Athol, Mass.; Ralph K. Lawrence, Simonds Saw & Steel Co., Fitchburg, Mass.; Donald McQuillan, Spartan Saw Works, Springfield, Mass.; Daniel K. Northup, The Henry G. Thompson & Son Co., New Haven, Conn.; Verne Olson, Contour Saws, Inc., Des Plaines, Ill.; and Phillip Rogers, Millers Falls Co., Greenfield, Mass.

Soaking Pit Capacity Cut, Ford Open Hearth Goes Down

Detroit

• • • **One open hearth** in the steel mill at Ford Motor Co. has been closed down due to shortages in soaking pit capacity pending rebuilding of the pits.

It was expected that two or three months would elapse before reopening of the renovated pits would make possible the absorption of all furnace capacity at Ford. The shortened space in recent weeks has built up an inventory of several thousand tons of steel ingots, and reduction of the furnace capacity in the weeks ahead will permit the working down of this stock.

OPA Mailing Simplified Financial Report Form

Washington

• • • **Mailing of a revised,** condensed, and simplified form on which many business concerns are asked to make annual financial reports to OPA has started. This revised annual financial report form, known as form A, has been reduced from 19 to four pages, and convenient 8½x11 in. sheets are used instead of the former legal size. This year's instructions are printed on one single sheet, which is the same size as the sheets in the form. The single sheet replaces last year's 12-page instruction booklet as well as some additional instructions that occupied several pages of the form.

Form B, the interim financial report, also has been simplified and shortened. Mailing of this form started March 10.

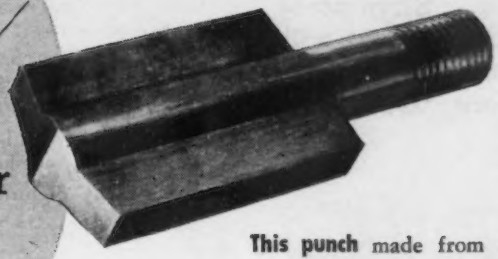
Only those concerns receiving the forms from OPA are being asked to file a report. Since OPA's information must be kept curent, those companies asked to file are also asked to make every effort to file form A within three months after the close of their fiscal year. Form B should be filed within one month after the close of each quarterly period.

The information contained in the returned forms gives OPA the basic background on trends in industry as well as specific information on differerft industry groups and for individual companies. Current information of this type is necessary for the continuance of a fair price control program. It also helps OPA to make quick and accurate decisions on many price problems.

The reports are confidential.

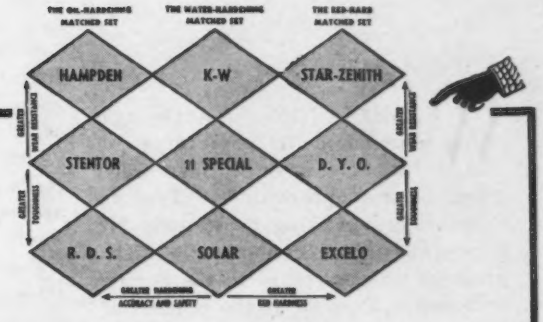
This tool for punching 3/16" thick O. H. steel sheet was made from a tool steel that promised to provide the *toughness* needed on the job. But excessive wear meant that the punch had to be reground after 190,000 holes had been punched.

Which OF THESE TWO TOOLS Will Stay On The Job Longer and Increase Machine Output Per Month?



This punch made from *Stentor* tool steel provided just the right combination of toughness and wear resistance for the job. With it, production jumped over 100%—to 387,000 holes between grinds!

here is WHY one tool does a better job...



The Carpenter Matched Set Method. It points the way to the tool steel properties you need for almost any job. Result — better tools, more output from machines and presses, lower production costs.

For example, you start with the diamond in the center of the diagram, *No. 11 Special* straight carbon (water-hardening) tool steel. But when you want greater *wear resistance,* you travel *north* on the diagram. For greater *toughness,* you go *south,* etc. Each of the *Matched Tool Steels* on the diagram picks up its job where another leaves off, so you know in advance just what results to expect.

A tool giving 100% more production isn't just a stroke of luck! The tool room foreman knew what he needed for the job. He had found a *definite system* for picking the one tool steel that would do the job best. And as the heat treater had complete, easy-to-use instructions, they got real results from the very first.

You can do the same thing, by following the Matched Set Diagram. Carpenter can give you a definite system for finding the best tool steel for each job. And when you put Carpenter's heat treating information to work, you get real results. Full information on the Matched Set Diagram together with an 80-page tool index and steel selector is given in the Carpenter Matched Tool Steel Manual. Free to tool steel users in the U. S. A. Write for your copy today on your company letterhead.

The Carpenter Steel Co., 121 W. Bern St., Reading, Pa.

L. W. MOFFETT

• Truman Committee pushes postwar reconversion plans . . . Answers defeat of tax amendment by saying advantages outweigh objections . . . Says postwar bond proposal will provide more cash for government use . . .

WASHINGTON — Although eliminated in conference on Jan. 21, after it had been given Senate approval, the Truman Committee is sticking to its guns for a postwar reconversion plan. The proposal was presented to the Senate by Senator Truman at the request of Senator Hatch, Democrat, of New Mexico, a member of the Truman Committee. It was offered as an amendment to the tax law designed to meet the postwar expense problem and was outlined in THE IRON AGE of Jan. 20, page 103.

The Truman Committee's recent annual report, emphasizing the necessity of postwar reserves for private enterprises, said that it is sincerely hoped that further consideration will result in the adoption of some such plan in the near future in order that the individual businessmen and corporations may use their individual initiative in planning a continued prosperity after the war.

The defeated amendment would have permitted the setting aside as reserves up to 20 per cent of the normal net income tax to be invested in a special issue of non-negotiable, non-interest-bearing government bonds, redeemable 18 months after the war. Upon redemption the income from the bonds would be subject to the Federal tax in effect at that time.

The report says that the vast majority of the men who manage our industries have no desire to be war profiteers, and that the renegotiation law has afforded them a convenient and systematic means of readjusting prices and profits to a mutually agreeable and fair basis.

"But," says the report, "industry does want a reasonable opportunity to preserve itself after the war; an opportunity to convert to full-scale peacetime production as rapidly as war contracts are terminated; an opportunity to make quick readjustments which will cushion the shock of discharges to millions of returning soldiers."

THE principal objections to the plan, the report said, seemed to be: 1—A fear that all taxpayers would claim the full 20 per cent deduction in figuring their current taxes, which would reduce the current tax receipts of the government by several billion dollars; 2—A fear that there would be a reduction in tax rates even within the first 18 months after the cessation of hostilities, which would mean that when the proceeds of the projected postwar bonds are returned to income that income would be taxable at a lower rate; 3—A fear that some of the money so set aside might be used by some taxpayers for expenses not strictly of a "reconversion character."

The Truman Committee, however, maintained that the advantages of the proposal far outweigh these objections and is expected to press for legislation putting the plan into effect.

The first objection was dismissed as being without merit because the government's present need is for cash to meet necessary wartime expenses. The committee pointed out that it makes no difference for current purposes whether the cash is derived from taxes or in another manner, provided the basis of obtaining the cash is in accord with principles of sound economics.

THE postwar bond proposal, it was explained, would provide more immediate cash than the amount of taxes, which would be lost because the full amount of the taxpayer's net income used for acquisition of these postwar bonds would immediately go into the Treasury, free of interest charges, whereas the highest tax rate applicable to such income is still substantially under 100 per cent.

The second objection—that there might be a tax reduction within 18 months after hostilities ceased—was declared to be one wholly within the control of Congress. If taxpayers are provided with the means for coming out of this war in a financially sound condition, the report said, it may not be necessary within the first 18 months after the ending of hostilities to reduce taxes materially.

"It may be easier on the taxpayers, whose solvency has been preserved, and sounder national economy," the committee tersely observed, "to keep taxes at a relatively high level now and for a time after the war, than to kill the taxpaying goose that lays the golden eggs now, and plan to do nothing more in the postwar period than weep over the corpse. There is something to be said for beginning now to consider reduction of our national debt in the years immediately following the war. Even if it should be possible to make such an immediate postwar tax reduction, however, a provision could be inserted in the proposed amendment which would prevent any windfalls to taxpayers receiving the proceeds of postwar expense bonds. The proceeds, to the extent that they are not used for purposes deductible as expenses under the then current tax law, could be subjected to tax at the same rate at which they would have been taxable

DR. WILLARD H. DOW: *Appearing before the Truman committee, Dr. Dow, of Dow Chemical Co., charged the Justice Department with falsely accusing his company of being linked with a German cartel.*

BULKY LOADS are easy to HANDLE with AMERICAN MONORAIL LONG SPAN CRANES

American MonoRail engineers solved the problems of long span multiple runway and inter-connecting cranes, furnishing plants of mammoth size with overhead transportation systems for the movement of massive loads. These remarkable installations, some equipped with over thirty miles of runway, may mean little to the average plant, but the tricks our engineers learned and their ability to solve such problems may be of real value to you. It will pay you to consult with the American MonoRail Engineer. Send for copy of book C-1.

in the year in which they were earned."

AS for the fear that some taxpayers might spend money for purposes which might not be deemed strictly "reconversion expense," the committee said that it is believed that an effort to police the spending of businessmen after the war would completely defeat one of the basic purposes for which this war is being fought.

Businessmen have tolerated, and in many cases welcomed, stringent regulations of their business in the interest of winning the war as quickly and economically as possible, said the report whose blasts against government regimentation must make the old Blue Eagle revolve swiftly in the grave to which it was consigned by the Supreme Court in the early New Deal days of setting business to a goose-step tempo.

"One of their reasons for being willing to do so is to preserve in this country the traditional American freedom of business enterprise and initiative," the report continued. "The tax law and the interpretations respecting the preceding tax laws for the past 30 years have developed a great body of precedents as to what expenses are properly deductible in computing taxable income, what expenses are to be treated as capital investments, and thus subjected to the tax obligations of invested capital, and what expenses are to be treated as purely personal and therefore not entitled to tax benefits.

"Insofar as net incomes are radically reduced in the first 18 months after the cessation of hostilities in this war, it is perfectly reasonable to assume that substantially all of such reduction will be the direct or indirect consequence of economic conditions brought on by the end of the war. It is believed that the existing regulations under the tax law are adequate protection against the possibility of such reserve funds being spent in a manner not contemplated by the proposal. It is further believed that any attempt to set up a machinery for government policing of the purposes of individual and corporate expenditures after the war would involve a basic change in the American system and should not be tolerated."

Draft Boards Irate at New Ruling

Pittsburgh

• • • Local draft boards here, it is said, are incensed at a recent ruling of the State Selective Service, that review of industrial Manning tables is the prerogative of the state organization. A few weeks ago, drastic instructions had been sent out by the state, calling for review of occupational deferments. Most local boards at that time took this as authority to review for the purpose of reclassification all occupational deferments, regardless of whether they were included in Manning tables or not.

It is understood that a considerable number of Manning table deferments had been reviewed by the local boards before the state organization ordered local boards to refrain from any further action along this line until the state had completed reviewing industrial Manning tables.

Local boards here have indicated that they will not now review any more Manning table deferments until the state has completed its study. There is definite indication, however, that when the state has completed its review, local boards who claim they have the authority to do so may start their own reclassification.

On March 11, the State Selective Service director said that 600 of the state's 1940 industrial replacement schedules had been cancelled, that many others have been revised downward, and that cancellations and revisions will be continued indefinitely. It was also said that many schedules, which are allowed to run to their expiration date, will not be renewed. In all cases, it is said, that the local boards can consider the cases of men released through cancellations and revisions of manning tables.

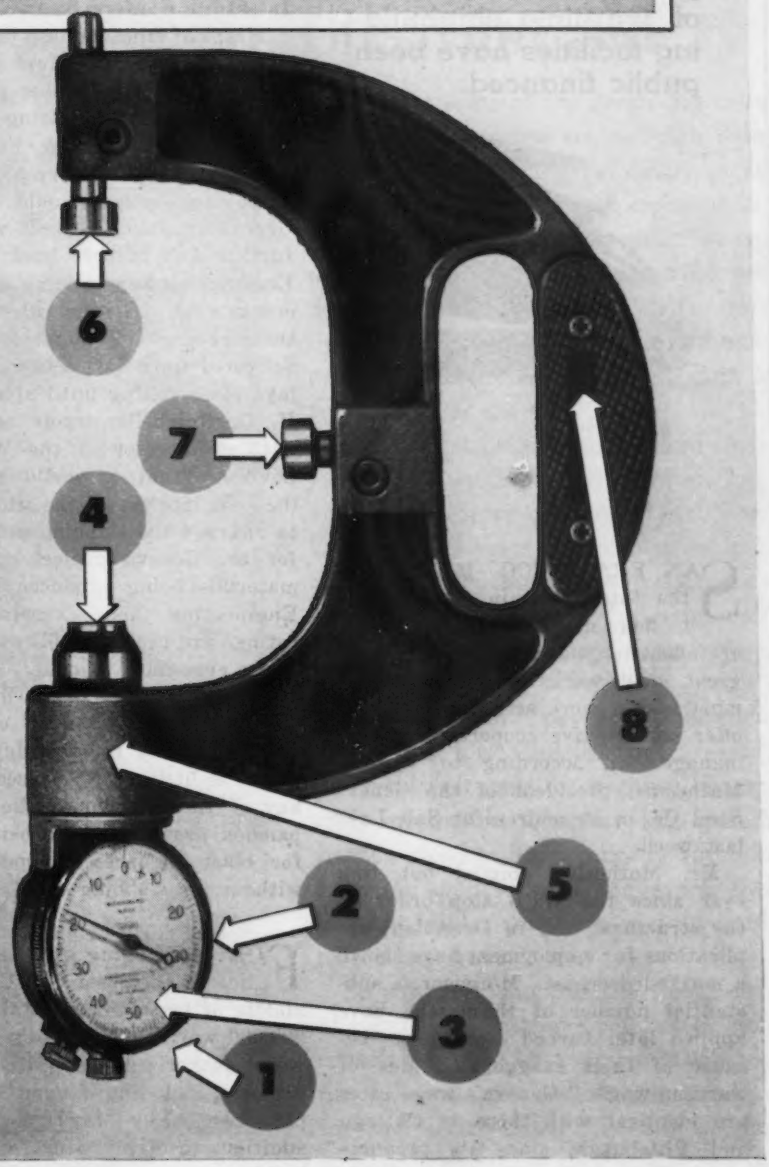
Midvale Nets $2,046,658

• • • The Midvale Co., Philadelphia, reported a net profit for 1943 of $2,046,658 after provisions for taxes, renegotiation of war contracts, and contingencies.

SHEFFIELD

DIAL INDICATOR SNAP GAGE

FOR INSPECTION AND CLASSIFICATION



1 Gage may be used with dial either at the bottom or the top, whichever is more convenient.

2 Dial is adjustable radially and can be swung through 360° to facilitate reading.

3 Scale has a range of .005"—each graduation .0001".

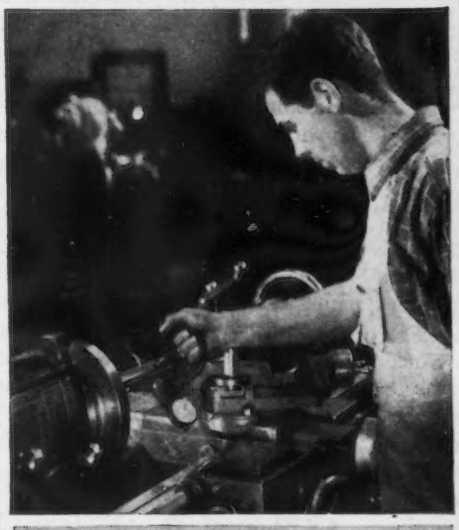
4 Movable anvil is spring urged for constant gaging pressure, but spring has no effect on indicator. Special spring pressures available.

5 Movable anvil bearing is long enough to preserve alignment with the fixed anvil.

6 Fixed anvil is adjustable to a maximum of one inch.

7 Adjustable backstop has a cylindrical face for accurate line contact.

8 Comfortable handle with plastic grip to insulate gage from heat of inspector's hand.



Work may be gaged to the accuracy of a one "tenth" indicator without removing it from the machine.

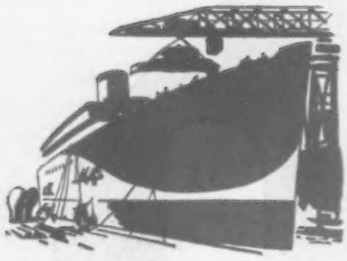
WEST COAST . . . OSGOOD MURDOCK

• If Utah and the Far West expect to hold heavy industry without subsidy, manpower and wages must be competitive . . . 96 per cent of war-time shipbuilding facilities have been public financed.



SAN FRANCISCO—If Utah and the Intermountain states expect to flourish henceforth in an age of industrial maturity, based on the great steel works at Geneva, they must take a more active interest and offer constructive cooperation to the management, according to Walther Mathesius, president of the Geneva Steel Co. in an address at Salt Lake last week.

Mr. Mathesius pointed out that ever since the WPB stop order on the structural mill in December, applications for employment have shown a marked decrease. Moreover, a substantial number of those who have applied later turned down jobs "because of their exaggerated idea of wartime wages." Geneva's wage rates are identical with those in Chicago and Pittsburgh, since its products must sell on the same market and for the same base. Although only 2500 workers are now employed there will be need for 6000 when the plant goes into full production. If local help is not available, it will be necessary to recruit and import men from other sections involving the possibility of social and racial conditions which have not hitherto existed in Utah.

At Salt Lake last week, Utah's Attorney-General Grover A. Giles released copies of correspondence between the U. S. Steel Corp. and the WPB which he had received from president B. F. Fairless of U. S. Steel Corp. to counter charges of delay and half-hearted management which had been made at the recent Interstate Conference at Carson City.

Most of the correspondence was concerned with the effort of the Corporation to obtain higher priority for the slabbing mill being built by United Engineering & Foundry Co. First scheduled to be completed so that plate production could start at Geneva in June, 1943, it was pushed further and further back as United Engineering kept getting government orders with higher priorities. Actually the slabbing mill materials were not delivered until last month which delays plate rolling until after April 1. H. G. Batcheller wrote on Jan. 13, 1943 as director of the WPB Steel Division "that it would not be for the best interest of the war program to upgrade the slabbing mill required for the Geneva project, since other materials being produced by United Engineering and carrying higher ratings are needed to fill war requirements even more critical." In March, 1943, Mr. Fairless advised the Steel Division that unless it could give higher priority for the slabbing mill "there is little use in proceeding with any of the balance of the steel expansion program, there being no use for blast furnaces or open hearths without the slabbing mill."

FOR shipbuilding expansion facilities on the West Coast up to the middle of last year, a total of $542,900,000 worth of materials and labor were authorized by WPB for 113 projects, including a number of complete new major Maritime yards and additions to other yards for all shipbuilding purposes except Navy Yards. Of the total, $20,900,000 or 3.9 per cent was privately financed and 96.1 per cent was publicly financed. Since 1939 contracts for 2500 cargo vessels and warships have been let and approximately half of this number had been delivered by the end of 1943, including approximately 14,000,000 deadweight tons of ships for the Maritime Commission.

Some 600,000 workers are employed by 200 concerns in the three Pacific Coast states and an additional 100,000 work for suppliers and subcontractors. Construction contracts through December, 1943, have totalled 6½ billion dollars with an additional 1½ billion in project orders to Army and Navy establishments, so that the total wartime value of Pacific Coast built ships now in prospect during the war is about eight billion dollars.

A PLANT to reduce bauxite ore to alumina with capacity of approximately 1800 tons per day, similar to the Bayer-bauxite plants in Arkansas, St. Louis, Baton Rouge, and Mobile is being actively sought for the Pacific Northwest to assure continued operation of aluminum reduction plants there situated. Since imported bauxite ore could enter the Columbia River just as well as the Mississippi River, it is suggested that the plant be situated on the lower Columbia between Longview and Vancouver. A wartime emergency transcontinental trainload freight rate of $8.65 per ton on alumina now applies, but since it takes two tons of alumina to make one ton of aluminum, there is a penalty of $17 per ton against aluminum produced in the Northwest, even under the wartime special freight rates. Production of aluminum in the Pacific Northwest is approximately 900 tons per day with present capacity, and, assuming that the war in the Pacific will last another three years, the immediate construction of the Columbia Bayer-bauxite plant is cited to release railroad equipment, save in freight costs and make self-liquidating the federal government's investment of nearly $1,000,000,000 in plants and power developments in the Pacific Northwest.

It is further pointed out that in normal peacetime trade, trans-Pacific ships return in ballast and could economically bring bauxite from the Dutch East Indies or Guiana, returning empty after delivering lumber, wheat, canned goods and the other outgoing shipments from Pacific Northwest ports.

AS normal decades of economic history and industrial development continue to be compressed and accelerated into mere months out on the far western border, with the pace continually faster and the end

Twin Disc Power Take-off Units provide machines like concrete mixers with power links that are easy to operate, have exceptionally long wear life and are simple to adjust.

Streamlining

THE STONE AGE

Even today, some of the things this country does with concrete are well-nigh unbelievable. Our towering buildings, gigantic dams and broad, smooth highways are among the world's wonders—and they represent herculean effort. Machines that produce man-made stone must be able to stand the gaff of construction work that brooks no delay. Their every part has to carry its full load all of the time.

Twin Disc Clutches are standard equipment on thousands of concrete mixers, large and small. Hence the Twin Disc Clutch Company's 25 years of specialization in industrial clutch design and manufacture has played no small part in fulfilling man's dreams of better housing, cheaper power, finer roads.

The point it will pay you to remember about Twin Disc Clutches is this. Besides power take-off units for machines like concrete mixers, the complete line includes friction clutches for practically any other industrial application. There are also Twin Disc hydraulic couplings and hydraulic torque converters.

So whenever you consider the question of clutches for machines you buy or build, consult the Twin Disc specialists who have the skill and experience to give you most for your clutch dollar. To find out how you can benefit from their advice and suggestions, just drop us a line today. TWIN DISC CLUTCH COMPANY, Racine, Wisconsin, (Hydraulic Division, Rockford, Ill.).

not yet for some time, assessors and tax collectors, boards of supervisors, and state legislatures are scratching their heads even more viciously than they did in the depression or in the year of the big wind. Instead of a landslide they are threatened with a land hide, insofar as tax liability and assessability are concerned.

In Multnomah County, Oregon, the Federal Maritime Commission pays no local taxes on a $46,000,000 investment in shipbuilding improvements and facilities. If privately owned, the personal property tax would be at least $1,000,000.

In San Francisco it is estimated that the city's annual tax loss, through federal appropriation of formerly taxable real estate and inability of the city to collect a personal property tax on materials and equipment in publicly owned war plants, is at least $1,625,000.

Los Angeles officials put the amount of taxable real estate and personal property taken off the books at $700,000,000.

In King County, Washington, it is estimated that 42 per cent of the actal property value is tax exempt.

Land owned by the federal government in nine central California coast counties, tributary to San Francisco Bay, now exceeds 1,100,000 acres according to a recent compilation by the State Chamber of Commerce and assessed valuation of federally owned property in this district is estimated at $43,524,733. In Monterey County alone 579,731 acres are federally owned, representing 27.25 per cent of all land in the area with estimated assessed valuation of $3,500,000. In little San Francisco County measuring seven miles square, the estimated assessed value of Federal real estate is $28,198,270.

Part of this huge total in real estate and improvements represents military and non-commercial operation but an increasing amount is in port and harbor facilities, shipyards, magnesium plants, aluminum plants, aircraft factories, and actual commercial production, transportation, communication, and distribution facilities, not to mention recreational areas, agricultural projects, and irrigation — reclamation — hydro-electric power ventures to which Paul Bunyan would point with pride and awe.

While the present honeymoon whirlwind is in progress, the problem is only academic, for other tax sources are productive and initial development brings easy money and bulging payrolls to each community. But the strain of readjustment on local government threatens to be disproportionate in this area, because of the concentration here of federal development. There is, therefore, unanimous approval of pending legislation to permit political subdivision to tax certain federal land and installations under mutually agreed circumstances.

Akin to the assessment problem is the total tax take. Just as take-home wages are the actual measure of the workers' income, so total taxes paid by everybody to everybody should be the final measure of drag on income. One-third of California's estimated $11,000,000,000 income for the fiscal year 1943-44 will go for payment of federal, state, and local taxes, according to an analysis by the California State Chamber of Commerce. The federal government is expected to collect $2,870,000,000 in taxes in California, the state government $470,000,000 and local governments $320,000,000.

Eric Johnston Warns Labor To Improve Its Policies

• • • **Warning labor** that it will be "socked" by laws and public feeling, Eric Johnston, president of the Chamber of Commerce of the United States, said that labor was headed for the same downfall as overcame management back in 1933, if it did not overcome many bad practices. In his talk March 13 at the Founder's Day dinner of Boston University, Mr. Johnston outlined "seven sins of labor" and then explained how management was once guilty of the same thing.

The sins to be overcome, he said, are: 1. Arbitrary refusals to accept workers into union membership; 2. Arbitrary crushing fines imposed on union members; 3. Unions who do not hold regular meetings or regular conventions or regular and free and fair elections of officers; 4. Failure to make public proper financial accounts; 5. Too many strikes; 6. Violence on the picket line; 7. Restraints on production.

When management rode high, Johnston said, it too was guilty of these sins as applied in its own field. In conclusion, he pointed out to both labor and management that they could do one of two things: "1. Go ahead and turn this country into a continuous brawl, and government will chain you both; 2. Make a better choice. Work together and stay free."

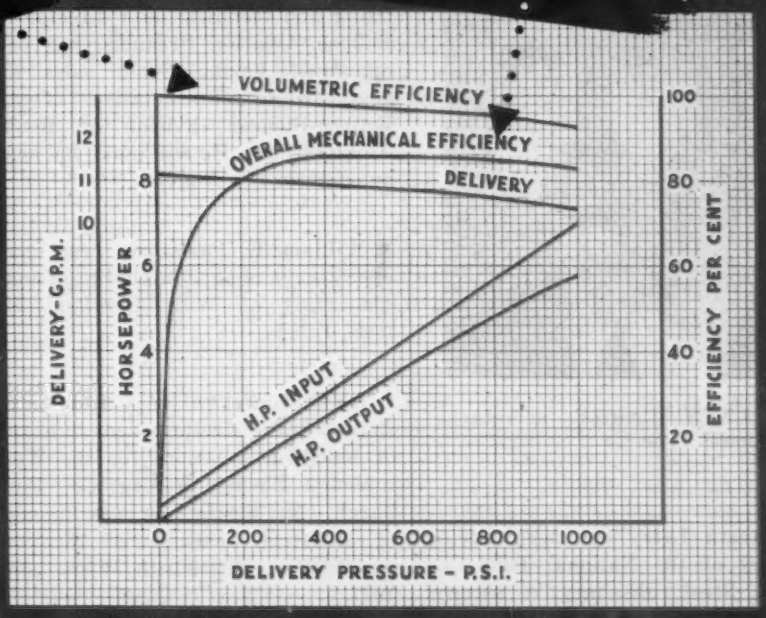
HIGHER VOLUMETRIC EFFICIENCY...

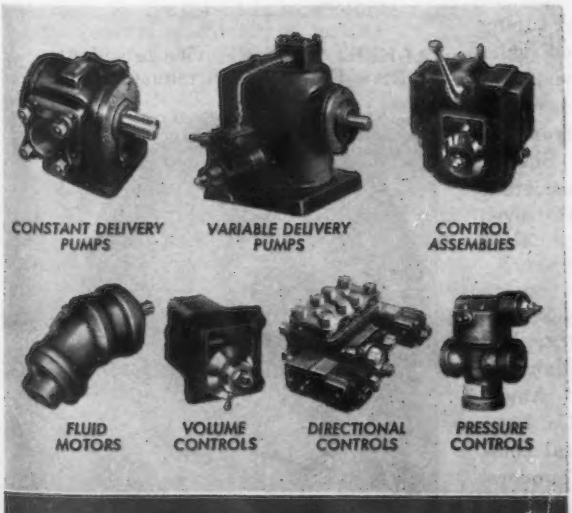
HIGHER MECHANICAL EFFICIENCY:



Typical curves shown are for V-104-D pump at 1200 rpm; curves for other models are similar. Above curves are for oil having viscosity of 150 S.S.U. at 100° F., temperature of 120° F.

VICKERS

BALANCED Vane Type PUMPS



Representative of More than 5,000 Standardized Vickers Units for Every Hydraulic Power and Control Function

These performance curves merit careful consideration when selecting constant delivery pumps for oil hydraulic power and control systems. The overall mechanical efficiency is extremely high throughout the important working pressure range. Note that pump delivery and efficiency are not reduced appreciably as pressure is increased. These features, together with the 1000 psi continuous working pressure that is possible, effect an important reduction in pump size and cost. This higher working pressure also means a substantial saving in first cost and in space occupied by cylinders, valves, piping, tank, etc. for a given speed and power.

Other important advantages of Vickers Balanced Vane Type Pumps include: (1) Hydraulic Balance which cancels out bearing loads and means much longer pump life, (2) cartridge assembly contains all pumping parts that move and is important to the simplicity, easy inspection and minimum maintenance of these pumps, (3) compact, yet rugged, (4) automatic wear take-up, (5) temperature adaptability, etc. Ask for Bulletin 40-25a for all the facts about Vickers Balanced Vane Type Pumps.

Vickers Application Engineers will gladly discuss with you how Vickers Pumps and Vickers Hydromotive Controls can be used to advantage.

PERSONALS

R. HEATH LARRY, secretary, National Tube Co.

• **R. Heath Larry** has been elected secretary of the National Tube Co., a U. S. Steel subsidiary, to succeed the late E. W. Criswell. Mr. Larry was formerly assistant secretary. Prior to his present connection he was with the law firm of Ruslander & Kaufman.

• **Anton Erhardt** has been appointed plant superintendent of National Tool Co., Cleveland, in full charge of its production of precision metal-cutting tools. He started with the organization 36 years ago as a punch press and lathe hand, and has since that time worked on every operation in the shop.

ANTON ERHARDT, plant superintendent, National Tool Co.

• **Sidney H. Webster,** former advertising and technical data director for Eclipse Aviation Products, has been appointed Pacific Coast sales and engineering representative of the Eclipse-Pioneer division of Bendix Aviation Corp. He will make his headquarters in Los Angeles.

• **William E. Paris** has been made operating manager in charge of manufacturing at Willys-Overland Motors, Toledo.

• **Ira B. Stiefel** has been made an assistant to the vice-president in charge of industrial relations for the Westinghouse Electric & Mfg. Co., Pittsburgh. Mr. Stiefel has been manager of industrial relations at the company's East Pittsburgh Works since 1937.

• **T. E. Marston** has been appointed manager of ring sales for the Edgewater Steel Co., Pittsburgh.

• **B. L. Weaver** has been elected a vice-president of American Wire Fabrics Corp., a subsidiary of the Wickwire Spencer Steel Co. In his new position he will have direct charge of all operations at the Mt. Wolf plant, Mt. Wolf, Pa.

• **Robert A. Campbell** for nearly 15 years associated with the steel tubing industry, has been appointed sales manager of the steel tube division of Talon, Inc. Mr. Campbell, a native of Youngstown, Ohio, comes from the Ohio Seamless Tube Co. of Shelby, Ohio, where he had been assistant sales manager for the past seven years.

• **Wallace Levi,** metallurgist, Lynchburg Foundry Co., Lynchburg, Va., and **Dr. R. A. Flinn** of the Mahwah, N. J., research laboratory of American Brake Shoe & Foundry Co. have been appointed to the technical committee of the Gray Iron Founders' Society.

• **Harlan P. Ross** has been appointed vice-president of the Upper Merion & Plymouth Railroad Co. with headquarters at Conshohocken, Pa. He succeeds Nicholas L. Moon, deceased.

RICHARD P. FIERST, treasurer, Superior Steel Corp.

• **Richard P. Fierst** has been elected treasurer of Superior Steel Corp., Carnegie, Pa. For the past 15 years he has been connected with the Bureau of Internal Revenue, Treasury Department, Pittsburgh office.

• **Leon F. Miller** has been appointed sales manager of the Osborn Mfg. Co., foundry machine division, succeeding **R. F. Lincoln,** who has resigned to enter another field.

• **W. S. Bowser,** controller, has been elected director of the Blaw-Knox Co., Pittsburgh. **Frederick Baker,** assistant treasurer, was named treasurer, and **Albert L. Cuff,** secretary and treasurer, was elected a vice-president.

ALBERT L. CUFF, vice-president, Blaw-Knox Co., Pittsburgh, Pa.

GEORGE A. SLOAN, member of finance committee, U. S. Steel Corp.

•George A. Sloan of New York has been elected a member of the finance committee of U. S. Steel Corp. to fill the vacancy caused by the recent death of William J. Filbert. Mr. Sloan has been a member of the board of directors of the corporation since Jan., 1937. He was president of the Cotton Textile Institute from 1929 to 1935.

• **Hardy B. Reisfeld** has joined Allis-Chalmers Mfg. Co.'s general machinery export department in Milwaukee. He is prepared for his present position by many years of representing industrial firms in Turkey, Sweden, the Balkans and Belgium.

HARDY B. REISFELD has joined the general machinery export department of Allis-Chalmers Mfg. Co.

• **George D. Wick,** executive vice-president since August, 1939, has been elected president of Fort Pitt Bridge Works, Pittsburgh. He succeeds **James M. Straub,** who has been elected vice-president in charge of production and costs.

• **John F. Budke** has been elected president of the Parkersburg Iron & Steel Co., Parkersburg, W. Va. Since 1924 he has been vice-president, counsel and director. **Charles F. Niemann, Jr.,** formerly assistant to the president, was elected executive vice-president and treasurer.

• **James Thomson,** former cost analyst at Gary works, Carnegie-Illinois Steel Corp., has been appointed assistant supervisor of the Carnegie-Illinois statistics division. **James W. Kettle** succeeds him. Mr. Thompson began his association with Carnegie-Illinois in 1933. **Gaston Estep** has been promoted to the position of supervisor of the analytical cost bureau with headquarters in Pittsburgh, and **Charles C. MacDonald** has been promoted to district supervisor of the analytical cost bureau, succeeding Mr. Kettle.

• **Walter S. MacNabb** has been appointed division superintendent of blast furnaces, Gary works, Carnegie-Illinois Steel Corp. He has served continuously since 1910 with the Gary organization, heading various plant departments.

• **J. Paul Oliver** has been made administrative technical assistant of the Research division of Cardox Corp., Chicago. For the last two years he has been superintendent of the Cardox electrochemical plant at Claremore, Okla. **Dr. Laurence M. Liggett** succeeds Mr. Oliver as plant superintendent.

• **George L. Davis,** who was formerly vice-president of the Diamond Power Specialty Corp., Detroit, has joined the Carnegie-Illinois Steel Corp., Pittsburgh, as general staff manager, sales. In the past, he had been in the employ of the American Steel & Wire Co., Donora, Pa.; Pressed Steel Car Co., McKees Rocks, Pa., and the Oliver Iron & Steel Corp., Pittsburgh.

• **George D. Sells** has been appointed superintendent of blast furnaces of Pittsburgh Steel Co., Monessen, Pa., and **Charles D. Steele** has been appointed assistant superintendent. Mr. Sells was formerly connected with the American Steel & Wire Co., at Duluth, Minn., and Mr. Steele has been with the Pittsburgh Steel Co. in the capacity of blast furnace foreman for a number of years.

• **H. P. Munger** has been appointed plant manager at Olean, N. Y., of two of the plants of the Van der Horst Corp. of America. Before taking over his present responsibilities, Mr. Munger was superintendent of the new electrotinning plant of Republic Steel at Niles, Ohio.

• **Frank J. Hirner** has been appointed manager, St. Louis district, of the Harnischfeger Corp. Mr. Hirner has served in various capacities in engineering and sales at the company's plant and field offices.

• **J. D. Glatz,** chief of the crane and hoist section, tools division, WPB, for two years, has been appointed manager of the repair sales division, Harnischfeger Corp., Milwaukee.

OBITUARY...

• **D. J. Higgon,** superintendent at Canadian Furnace Ltd., died March 5. He was 59 years old.

• **Jesse S. Draper,** former Detroit representative for American Cable & Chain Co., died recently. Mr. Draper was one of the founders of Hudson Motor Car Co.

• **Newton S. Taylor,** 55, an executive in the switchgear and control division of the Westinghouse Electric & Mfg. Co., died Feb. 21 at his home in Wilkinsburg after an extended illness.

• **Marvin J. Steele** died at Detroit Feb. 29. He was assistant chief engineer of the Marine Engine division at Packard Motor Car Co., which he joined 32 years ago.

• **William E. Hyatt,** retired manager of U. S. Steel Export Co. of New York, a subsidiary of U. S. Steel Corp., which he served for 50 years, died March 6 at the age of 76.

• **Bert G. DeWitt,** superintendent of the enameling department of Geuder, Paeschke & Frey Co., Milwaukee, and with the firm 33 years, died March 2 at his home there.

Fatigue Cracks . . . .

BY A. H. DIX

Ingenious, Uninhibited

• • • A constant marvel to us is the inventiveness of the artist who illustrates *The Mainspring*, Wallace Barnes Company's house magazine, a Baedeker of spring lore.

While the text is serious, as befits the subject, the illustrations are not. The artist is given free rein in drawing sketches that will sharpen the points brought out in the reading matter, and he performs his assignment in an ingenious and highly uninhibited manner.

"Outdoor exposure and constant handling"

For example, when confronted with the job of illuminating the line, "Nickel plate will tarnish under outdoor exposure and constant handling," he produced the bathing beach love scene at the right. It seems to us a perfect fit.

Aptronyms

. . . The retiring president of the Canadian Jersey Cattle Club is Duncan O. Bull.

—*Robert Trowbridge, Arvida, Quebec*

How about "Air Surgeon," the new book by Frank G. Slaughter?

—*G. M. Swanson, San Francisco*

Head of the Toledo, Ohio, diocese is Bishop Karl Alter.

—*E. J. Ehret, Chicago*

Clean Hit

. . . As to the versank-versenkt controversy, since both John H. Van Deventer and Ingo Maddaus are old friends of mine, I cannot be accused of being partial when I tell you that Ingo is right.

In the sense used by John H., the announcement comes from the submarine captain who would report: "The ship was sunk (= wurde versenkt), while the captain of the victim would report the fact that his ship sank (= versank). In other words, it depends on the point of view.

—*G. H. Zimmer, Buffalo Forge Co., Buffalo 5, N. Y.*

He went Back 921 Years

• • • A "T" for Timeliness to whoever handles publicity for Detecto Scales, Inc., 1 Main St., Brooklyn, N. Y., for sending us this medieval painting of scales in use about a thousand years ago.

The timeliness comes from the fact that the painting is in an encyclopedia completed in 1023 by the monks of the Monastery of Monte Cassino.

No Esses

. . . We have a problem. For purposes of filing applications for allocations of copper oxide, we would like the plural of ship-bottoms paints.

I am putting the form through as "ships-bottoms" paints, but somehow it doesn't seem right, as it implies a ship has more than one bottom. But "ships-bottom paints" I translate to mean only one bottom for all the ships. Or should it be "ship-bottom paints"?

—*E. A. Bostrom, Pope Trading Corp., New York*

"Ship-bottom paints" wins by a 5 to 2 vote of the brains department's marine division, hull section. The minority opinion holds that the requisition should read "Enough paint to coat hull of a .....-ton ship." If several hulls are to be painted, follow the example of the tailor who solved the problem of ordering more than one tailor's goose by adding a postscript, "Better make it two."

Second Taker

• • • An English manufacturer writes us that he was threatened with violation of copyright because he drew upon data in an English publication in preparing some publicity material. Recalling vaguely that he had seen the same information some place before, he went through some old copies of your favorite family journal, and found that the English publisher had lifted the data almost bodily from us.

Inasmuch as so many of the industry's new developments are first published here, THE IRON AGE is a favorite source book, a situation we view more with satisfaction than alarm. So when we run across an echo of a shout of ours that broke the silence on a given subject, we are inclined to glow rather than glower.

A cry of anguish escapes us only when whole pages of the brains department's deathless prose are copied, complete with drawings, without even a fine type bow in our direction.

Blurb

• • • As an example of an uncommon information carrier's contribution to the literature on a given subject, we cite the 20-page report on direct casting in the Feb. 24 issue. This, together with the previous report that appeared in our Apr. 4, 1940, issue, constitutes practically the whole of published literature on this epoch-making development.

Stopper

• • • Buxom Bertha Knows Her Batch Control.—*Toledo Scale Co.*

Kremlin Favorite

• • • Knife-sharp, trim-figured, magnetic Eric Johnston, head of the U. S. Chamber of Commerce, says Russia will be a major postwar market for American goods. If so, those who are smart enough to advertise in your family journal will have a lead of many versts on their less astute contemporaries, for this is one of the U.S.S.R.'s favorite foreign industrial journals.

Back in the '20s, when that country's industrial program was just getting under way, we were one of the dozen or so American publications on the approved list, despite our frequent divagations from the straight party line. The Russians are hard buyers and their love for us is due solely to our high information-roubles ratio.

The love persists, for last year when we feared that paper rationing would force us to reduce the number of copies going to Russia, Moscow cabled us:

INSIST YOUR FILLING TOTAL QUANTITY REQUIRED. PLEASE WIRE CONFIRMATION.

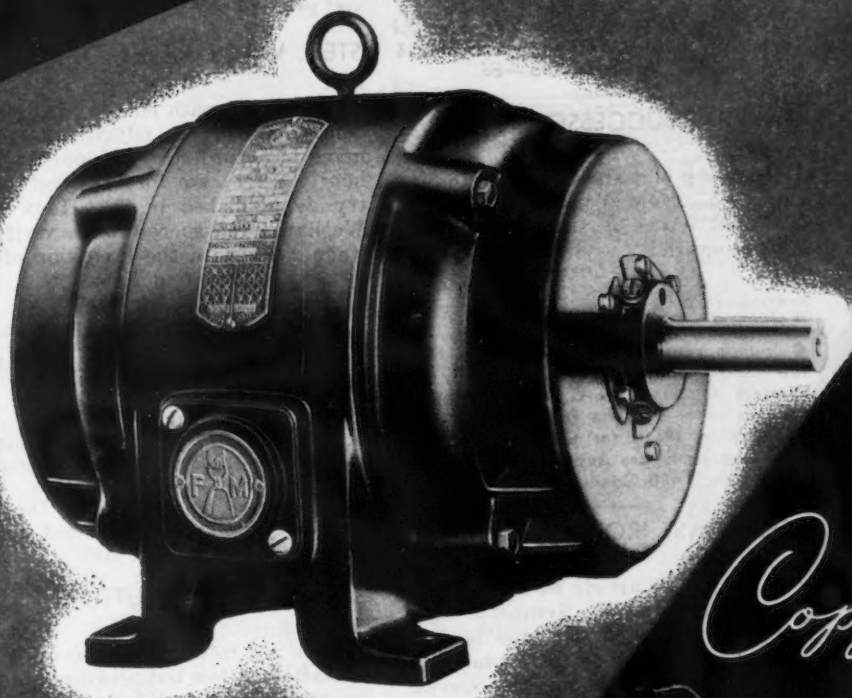
Puzzles

Last week's butcher uses these weights ½, 1½, 4½, 13½ and 40 lb.

You should get this in five minutes:

The owner of a small tool and die shop, having 13 employees, wishes to give an Easter turkey to all but one trouble-maker. But he does not want the trouble-maker to know he is being discriminated against, as that might cause trouble with the union. So he arranges the 13 in a circle and says "Every ninth man gets a turkey." As soon as a man gets a turkey he steps out of the circle. Where did he place the trouble-maker to keep him turkeyless?

A Challenge to the Future ...in Motor Design



Copperspun ROTOR

Here is the new Fairbanks-Morse general purpose, continuous duty motor—designed for the future—available now! Never have more stamina, versatility and protection been built into a motor housing!

BUY WAR BONDS

NOTE THESE FEATURES

- **It is a 40°C. motor.**
- **It is a protected motor.**
- **It has an optional conduit box assembly.**
- **It has cross-flow ventilation.**
- **It has ball bearings—sealed in cartridge type closures.**
- **It has exclusive Fairbanks-Morse *COPPERSPUN ROTOR.***

Dear Editor:

MUSLIN RUST PREVENTIVE

Sir:

Page 58 of your Feb. 3 issue states that clean iron surfaces protected by a muslin cage do not rust freely. We have been dipping these muslin cloths in oil. Have any experiments been made along this line? The thought that occurs is whether the oiling operation on our part is unnecessary.

JOHN C. KERR,
Chief Inspector
Wayne Pump Co.,
Fort Wayne 4, Ind.

● Our news item was based on a corrosion investigation made at the National Physical Laboratory, England. Whether or not immersion of the cloths in oil helps or hinders, we do not know. Has any reader had experience with this?—Ed.

WELDING STRESSES

Sir:

In regard to the locked-up stresses due to welding, the Lincoln Electric Co. has referred me to your Sept. 2 article, "Control of Residual Stresses Through Welding Sequences." Are reprints available?

L. S. BEEDLE,
Lieut., U.S.N.R.
Norfolk Navy Yard,
Portsmouth, Va.

● No reprints were made but a clipping is being sent.—Ed.

BRICKBAT

Sir:

I quit reading the editorials as they play only one tune, namely, labor strikes and business is holy and righteous, and professors are not practical. I happen to work for a living and as a sideline I even teach school (you know, long hair, New Deal, professor type), so I resent your aspersions as to my practicability just because I happen to be educated. Do you have to be a moron to be eligible for office in Washington? Also, by the way, does free enterprise consist of the right to sell defective materials to the Government if you can get away with it? A harp has many strings, why don't you play the low notes awhile? My ear is tired of the high notes. For every union there is a cartel. For every lousy leader there is an unscrupulous business executive, and I thank God there are a few long-haired guys with a grade of intelligence a little higher than a moron who can offset organizations like N.A.M.

ASST. CHIEF ENGINEER

● That all business is lilywhite and all unions uniformly black is no contention of ours. In both groups there are intermediate shades.—Ed.

HIGH CONDUCTIVITY PLATE

Sir:

We have read with a great deal of interest the article on page 47 of your Feb. 3 issue regarding the new metal plating process using ingots made of copper, tin and zinc for providing high surface conductivity.

Where can we get more information?

J. H. KRAEMER,
Superintendent
Brier Manufacturing Co.,
Providence, R. I.

● From Hendley Blackmon, Director of Technical Publicity, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.—Ed.

GARVIN'S SUCCESSORS

Sir:

How long is it since the Garvin Machine Co., New York, went out of business? Was it succeeded by another concern?

J. LOUIS SCHRADE,
President
Schrade Cutlery Co.,
Walden, N. Y.

● Garvin suspended business about 1923. The Garvin tapper is now made by the Western Machine Works, Holland, Mich., and the miller by John Frew Machine Co., Philadelphia. Parts for Garvin millers and screw machines are supplied by John B. Stevens, Inc., 480 Canal Street, N. Y.—Ed.

COLD-BLAST IRONS

Sir:

J. E. Hurst's article on "Cold-Blast Irons Duplicated by Synthetic Mixtures" in your Feb. 17 issue is very interesting but somewhat tantalizing, because the context does not reveal whether the "cold-blast" pig irons were made with charcoal, raw coal, or with coke. In this country all "cold-blast" pig irons were made with charcoal.

The author mentions "cold-blast" and "charcoal pig irons" in his second paragraph, apparently differentiating between cold-blast pig iron and charcoal pig iron. Throughout the balance of his article he refers only to "cold-blast pig irons" and "ordinary refined iron."

Until this question of what blast furnace fuels were used in producing the two kinds of pig iron which were tested by Mr. Hurst is answered, it would be futile to come to any conclusions as to what extent his interesting laboratory experiments can be used in discovering the "It" in charcoal pig iron referred to in the article on "Charcoal Pig Iron" in your July 1, 1943, issue.

RALPH H. SWEETSER,
Blast Furnace Consultant
7 Mitchell Place,
New York

● Will Mr. Hurst, to whom a marked copy of this page is being sent, please say what fuel was used?—Ed.

COMPARABLE TOOL STEELS

Sir:

Do you have a chart showing the comparative relationship of various steels? For example, if we have one brand of Ketos steel, with a chart of this sort we could determine what other brand would be relatively similar. We are trying to set up a chart whereby we can place our steels for instruction in speeds and feeds.

W. H. SKINNER,
Purchasing Agent
Perfect Circle Co.,
P.O. Box 331,
Richmond, Ind.

● See the "Chart of Comparable Tool Steel Grades," in our Aug. 28, 1941, issue. Reprints are available and one has been sent you.—Ed.

STEEL WAGE RATES

Sir:

A contract with one of our vendors calls for a price adjustment to be made in accordance with our average hourly wage rate for the steel industry as published in THE IRON AGE. We have been successful in verifying wage rates with the exception of the months of Jan. and Feb., 1943. Can you tell us what they are?

R. D. McCALL,
Chief Clerk,
Material & Supply Division
Hercules Powder Co., Inc.,
Sunflower Ordnance Works,
Lawrence, Kansas

● The American Iron and Steel Institute from which we obtain our data states the average hourly wage rate for Jan., 1943, was $1.107 and for Feb., $1.105. The average hours per week were 39.8 and 41.6 respectively.—Ed.

COLD TREATING CUTTING TOOLS

Sir:

We are interested in securing information on low temperature quenching and hardening of steels.

The process as described to us is as follows: take the steel article such as a drill and place in a refrigerator and cool to a low temperature and let remain for a few hours, remove tool from refrigerator and allow to come to room temperature. The tool is then supposed to be several points harder. In fact one heat treating shop claims that the effect is equal to that of nitriding.

Any data you can furnish us will be appreciated.

J. R. GAGE,
Research Department
Goodyear Tire & Rubber Co.,
Akron 16, Ohio

● Some information on the cold treatment of cutting tools is given in the article, "Cold Treatment of Metals," which appeared in our Feb. 25, 1943, issue. For further data see "Some Effects of Sub-Zero Cooling" in next week's issue.—Ed.

GALVANIZING

Sir:

Do you know of any good books on hot dip galvanizing?

RAYMOND MATTE,
Engineer
Canadian Tube & Steel Products, Ltd.,
P. O. Box 67,
Montreal, Quebec

● The best book we know of is "Galvanizing" by Heinz Bablik, a German engineer. The English translation has been published by the Chemical Publishing Co., 148 Lafayette St., New York, $8. Wallace G. Imhoff, Vineland, N. J., consultant on hot-dip galvanizing, has also published data on the subject.—Ed.

The Steel Age

MORE than ever, industry, people and governments realize the vast importance of steel—for matériel of war and for a better peace. Transue, too, places its faith in the future and finer things for living in America's utilization of steel. For strength, lightness and adaptability, Transue deep drawn steel stampings again will contribute to the superiority of many products for civilian use.

This Industrial Week . . .

- **Steel Demand and Production at Frenzied Levels**
- **Loaded Order Books, Manpower Shortages Appearing**
- **Maritime Indicates Heavy Needs in Third Quarter**

DEMAND and production of steel for war are at such frenzied levels that problems of inadequate manpower, overburdened equipment and badly congested order books are returning rapidly and perhaps more forcefully than at previous periods in the past two years.

Deluged by plate and sheet orders, several flat rolled producers report that their carryovers of scheduled but unrolled tonnage have risen recently despite record output. In addition to forcing acceptance by mills of large tonnages of sheets and plates, WPB is giving mills large amounts of semi-finished products to be produced during second quarter for Lend-Lease.

The manpower pinch is growing tighter. The big drive by Selective Service, responding to the urging of the President, has resulted in cancellation of industry replacement schedules and other severe steps in some areas. The serious shortage is in common labor. With employee ranks being depleted, inefficiency, which is already estimated at 23 per cent above normal by at least one representative steel maker, will rise higher. Repairs are now taking longer to complete than was formerly the case, a situation which presents a threat if all-out production is to be required over any length of time.

In the Buffalo area, the manpower shortage is making it impossible for two large steel plants fully to meet schedules, particularly in the open hearth maintenance departments. Lack of labor also has hampered blast furnace repairs.

"WE have been able to produce as well as we have only by men working long hours, 16 hr. per day or seven days a week, but there is a limit to human endurance," said the manager of one Buffalo steel plant.

Foundries, struggling with the manpower stringency, are endeavoring to sublet castings contracts through the aid of pig iron salesmen, who are in touch with plants which might handle additional business.

OPA is reported to be drafting an announcement regarding carbon steel prices after a meeting held last week in New York with the Steel Advisory Committee. Apparently, both sides have exhausted discussions on what the confidential figures have shown, and it now appears that the possible slight downward revisions and some upward adjustments may have to be fitted into the general stabilization picture. OPA also is working on its alloy steel, merchant iron, and merchant ore studies.

WPB has decided to revoke its order stopping construction of the structural mill at Geneva, Utah. At the same time it is reported that completion of the South Chicago plant of Republic Steel Corp. has been approved. The first action is a source of good news to the western bloc in Congress, which has been exerting pressure against the stop order. The second action will give DPC a completed plant through expenditure of only a small amount of money, since the Chicago installation was almost completed, with its coke ovens consuming much gas.

Highlights include: Donald M. Nelson's statement of WPB reconversion policy in which he admitted that the services have not always consulted with WPB on contract cutbacks; the dragging on of the WLB steel wage hearings with little being accomplished from day to day so far; cancellation by the Navy of its 16 gage cold rolled sheet container program; the appearance of strong indications that 1945 airplane production will be larger than ever; and the Truman Committee report that magnesium output is at a point where its use in more civilian goods is warranted.

ADMIRAL Emory S. Land on March 9 said that this year's shipbuilding program will run into 1945, although it is yet uncertain what exact tonnage will be built in the first half of next year. While it is conceded by WPB officials that the Maritime Commission will have all of the steel needed for 20,000,000 tons of shipping, the production goal for 1944, by the beginning of July, tentative discussions with WPB indicate that the Commission will require about 475,000 tons of plate a month in the third quarter. This would indicate a shipbuilding program of at least 10,000,000 tons is in prospect for next year, provided Maritime succeeds in building 2000 ships this year. While first quarter allocations of plates to the Maritime Commission amounted to about 560,000 tons monthly, second quarter allocations were an estimated 525,000 tons monthly.

Latest information on the new all-metal shell container program currently being placed by Army Ordnance is that production may center in the Cleveland and Chicago areas. Four sizes of a tubular shell container which will be water-tight and reusable are being made in Cleveland and at least four additional sizes of a different type are reported being made in the Chicago area. The four tubular types

will hold respectively 57 mm. and 81 mm. mortar shells, and 90 and 105 mm. high explosive shells. Steel specifications are calling for both hot and cold rolled SAE 1010-20 sheets and strip. A great deal of idle and excess steel is expected to be pressed into service. The tubes for the body are welded from formed sheet. It appears that approximately 70,000 to 75,000 tons of sheet and strip will be used in the Cleveland district. Estimates of the sheet tonnage by the entire program are said to exceed by 35 per cent the sheet requirements of the automotive industry for the comparable quarter of best peacetime year. Some 1732 miles of 6-in. welded sheet tubing will be required in Cleveland and 2763 miles of all size tubing in this area. Smaller mills not closely tied in with plate production are getting a majority of sheet orders.

AFTER analyzing the Murray plan for assisting 20 of the smaller steel companies, opinion in the industry seems to be that legal problems concerning the use of DPC furnaces would be formidable, that shipments of such pig iron would be at the expense of other tonnage, and that the small steel companies still would have no guarantee of adequate orders. It is pointed out that the history of the steel industry shows that when supplies are in balance or in excess of demand, so-called premium prices cannot be realized. Some executives assert that the Murray plan might be an entering wedge for wide-scale government participation in the steel industry.

Several of the smaller steel companies in the Illinois-Missouri area, queried concerning their reaction to the Murray plan, denied that they were confronted with a disastrous scrap shortage and pointed out that increased labor rates had been as great a factor in raising their overall production costs as had the cost of raw material. An overall price increase would be a better solution than the Murray plan, it was said. Two of the mills mentioned by Murray are reported to have offered indirect price concessions recently on wire product sales.

Corrollary to the expected farm equipment boom which is leading many firms who have never before made farm equipment to consider entering the field as soon as possible, is the tremendous increase in farm demand for steel and particularly wire products. Priorities cut the farm market in half in 1942 but last year sufficient steel was released to farmers to enable close-to-normal sales. This year is expected to be 50 per cent better than 1943.

Sidelights of Week's Market Summary

• • • The WPB Steel Division is slated to have a new director, according to unofficial Washington gossip. . . . One of the large new plate mills was turned over for the first time recently but still lacks its shear . . . Several steel companies are showing distinct interest in Mexico as a postwar market . . . WPB is reported to have cracked down upon a steel company by installing a compliance officer at the main office . . . Trying to build 10,000 caterpillars proved far more difficult than a locomotive manufacturer ever imagined and some of the work may be farmed out . . . The U. S. is slated to furnish 73 per cent of the soldiers to be used in the invasion of Europe, Congress has been told . . . WPB is muttering about firms which haven't been making their full quota of repair parts for civilian appliances . . . DPC's magnesium smelter at Ford Motor Co. has been ordered closed . . . The entire matter of experimenting with civilian output in Philadelphia, Kansas City and Cleveland is a source of great embarrassment to WPB in view of the setbacks which the program has received . . . Trade sources expect that a billion beer cans will be made this year, mostly of electrolytic plate . . . Some of the most sensational material uncovered by the Truman committee investigating war production has never been made public . . . One question being asked unofficially in Washington is whether Great Britain might begin returning machine tools and other equipment under lend-lease provisions.

Every HOBART WELD is a "STRONG" Argument for...

Industry everywhere is turning to "Simplified" Arc Welding to help them reduce prices, meet accelerated production schedules and produce a better, stronger product.

Construction engineers are finding more uses each day for "Simplified" Arc Welding. No job too small, no job too large to benefit from its advantages.

Remote Control, an exclusive Hobart feature, lets the operator get fine adjustments right at his work no matter how far he may be removed from the Welder.

Hobart "Simplified" Arc Welders are now available for immediate delivery to industry, repair shops, construction companies, etc., for needed work. Ask us for details.

HOBART "Simplified" ARC WELDING

Hobart Welds are strong welds . . . consistently . . . because Hobart engineering and design has "simplified" Welding Control. Weld quality depends upon proper current selectivity, which you get in a Hobart with radio type accuracy and ease. Just select the proper one of ten ranges by turning the "steering wheel," then get it down to fine adjustment on the small control dial. This quick operation gives you the selection of 1,000 combinations of voltage and amperage . . . the big answer to quality welds. And it's this accurate selection that you need to compensate for the other variables in welding . . . the various metals, positions of welding, thickness of metal, type of weld desired, etc.

Plenty of copper, two-way ventilation, separate four-pole excitation, plus many other design features, give Hobart Welders the ability to carry the load through grueling hours of steady work.

Hobarts have done much for the war effort. What they have done for others, they can do for you. Use the convenient coupon for full details.

HOBART BROS. CO., Box IA-333, Troy, O.
"One of the World's Largest Builders of Arc Welders"

Know Modern ARC WELDING

516 pages and 512 illustrations. Latest techniques, methods and procedures. Handy reference index.

Used by leading Training Schools and Colleges. Great aid to experienced operators, designers, superintendents and students. Tells how to use latest rods, equipment, and methods to obtain maximum production. Clearly, expertly written. Most modern book on subject available today. Sent subject to your approval. **$2.00** postpaid

Time Rolls on; WLB "Hearings" Badly Mired

Washington

• • • No law, no reason, no logic—these are the rules governing the farcical travesty of the WLB hearings involving the United Steel Workers, the steel industry and other allied industrial unfortunates who have signed USWA contracts.

The panel which is supposed to clear all extraneous questions aside, has held practically a week of "hearings" since March 8 which to date have fostered only more questions. Panel members are: David L. Cole, chairman; N. P. Feinsinger, vice-chairman; Hugh Morrow and Edwin D. Bransome, industry members; and John Despol and Stephen Levitsky, labor members. "Procedures" are so confused the hearing on the merits has been postponed from March 14 to March 22.

These are the questions to which there has been no answer or substantial agreement from the panel, USWA, nor from the heterogeneous hundreds of companies included in CIO's basketed demands.

How many panels shall consider the case, and what are the divisions of industry before each panel?

Has WLB the authority to consider a wage demand which will wreck the "stabilization program," and bury the "Little Steel" formula already killed by the bituminous coal case? This point was raised at a "procedural" hearing on March 9 when Attorney John C. Gall, representing Youngstown Sheet & Tube Co., startled the panel and USWA counsel by suggesting that the 17c. an hour wage increase be excluded because it would violate the stabilization policy.

Should panels consider the case from a plant or company basis?

What is the definition of the "basic" steel industry, and if an acceptable definition is arrived at through industry and union agreement, what difference will it make in WLB policy?

What instructions, if any, shall be given to the Regional Boards concerning steel cases now before them?

What issues or groups of issues shall the panel consider and in what order?

The reason for all of the confusion is the panel's failure to establish its own procedure as all other administrative tribunals do. Instead, these questions have been thrown open to a series of so-called hearings which at best have turned into declamation contests with the panel as a group of too-puzzled onlookers.

The union would like to have one panel hear all of the issues involving 1000 companies and several scores of issues. So far CIO-USWA has confined its idea of issues to its demands and the demands industry may make have not had any place in discussion. It is assumed that mere disagreement with some issues which CIO has batted at a miscellaneous group of industries will not satisfy many industrial groups which may have issues of their own to present.

Imagine the futility of a crowd of 500 sitting together for days playing the game of "What is the question?"

Thus far, the formula is something like this: WLB sends out telegrams to various companies which have USWA contracts to come to Washington to discuss procedures because CIO said so. About 500 people turn up representing hundreds of conflicting industrial concerns and industrial conditions. CIO General Counsel says it should have been 128 and Steel Panel Chairman Cole allows it should have been about 900 to discuss the procedures WLB has said will be discussed.

At the opening of each day's hearing, union representatives exchange glances confidently; steel men look at each other knowingly and at the panel members expectantly. Panel members either look quizzical or poker-faced.

Then comes a weary several hours of speaking by industry groups who do or do not want to be included in the "basic" steel industry's case. Thousands of words of testimony are put into a record which when finished promises to be as voluminous as an encyclopedia. Time staggers on, and when the day is over, 500 men have accomplished exactly nothing.

Utah Steel Plant May Be Completed, WPB Says

• • • **WPB** has made a new decision on the structural steel mill at Geneva, Utah. Because the supply of structural shapes had exceeded demand, WPB decided last December not to permit the completion of this plant of the Geneva Steel Co., but on March 13 WPB said that construction of the structural mill is being permitted to proceed to completion.

This mill has a rated capacity of 200,000 tons annually. The total cost was estimated at $17,250,000, of which the work remaining to be done should come to approximately $1,350,000. It is believed that it will take approximately three months to complete the work remaining, WPB officials said.

Completion of the Republic Steel Corp. plant at South Chicago has also been approved. See page 109.

Murray's Plan Seen by Some Persons As Inducing Government Participation

By TOM CAMPBELL
Pittsburgh Editor

o o o

• • • **No matter** which way you cut it, Phil Murray's plan to "save small steel" still means a combination of government subsidy, possible government control, lack of realistic planning, and forced support from larger steel producers, according to a cross-section of opinion in Pittsburgh.

The Steelworkers' Union plan, to aid 20 or more small integrated steel plants by suggesting a lower price for pig iron and scrap than now constitutes the going price, is symptomatic, according to reliable opinion here, of a problem which goes far deeper than the more or less superficial program set forth by Philip Murray.

For the past several years, wherever steel men gathered, a major point of discussion has been: "How will the little fellows hold on?" Just as timely a subject has been the question: "How long will the big fellows continue to sell raw materials or raw steel to smaller firms, which compete on the finished steel basis?" The latter question is not involved in Mr. Murray's plan, except that he overlooked the fact, apparently, according to authorities here, that any iron produced in DPC plants would have to come out of the hide of either larger steel companies or small merchant blast furnaces, who previously had been furnishing such iron. This viewpoint, it is said, is predicated upon public statements by WPB that sufficient pig iron is available, so that the operation of five DPC blast furnaces is not necessary.

Mr. Murray, as well as steel companies, big and small, have all been of the opinion that if war demands did not completely utilize iron and steel making facilities, then WPB should take up the slack by expanding civilian requirements.

If the above situation is true, as all reliable reports from Washington indicate, then the steel companies, which Mr. Murray is championing, would probably not obtain any more orders than they are now obtaining; and if his plan were adopted, these companies would obtain special operating cost concessions, not available to other steel makers. In the meantime, the producer of the pig iron made in DPC plants would ship such pig iron either at the expense of tonnage from his own blast furnaces, or at the expense of small merchant furnaces who may have been supplying the iron. The latter, who have been clamoring for higher prices, would then, it is said, be in a precarious position themselves. If the supplier of the DPC pig iron happened to be a larger steel company, it would not make any difference whether it came from their own furnace or the DPC unit. But it would mean that if it came from their own furnace they would be denied a profit on the iron, which they had been obtaining, and if it came from the DPC plant they would have to use their own raw materials, pay a royalty tonnage figure to the government, and pass out the iron at practically no return to themselves.

On the question of supplying battlefield scrap at lower than ceiling prices to the small steel companies mentioned, it is recalled that such scrap is being handled entirely through dealers, who have taken on the momentous job of segregating it. Even though these dealers were ordered by WPB to follow Mr. Murray's plan of selling at lower prices, the difference, theoretically, would have to be made up by a government subsidy. Practical scrap observers know, however, that higher scrap prices for any item last just long enough for buyers to find a cheaper price.

Some steel people, and they do not all come from large companies, see in Murray's plan an entering wedge for governmental participation in steel industry.

Critical Analysis of Portions of Murray's Small Steel Plan

Pittsburgh

The pig iron should be sold at that discount below the current OPA ceiling prices as is found necessary to enable the small producers to be competitive, but not less than the cost of production to the DPC.

If the DPC agents sell this pig iron, it is they who are selling it and not the DPC, since they pay the latter a stipulated amount per ton of pig iron produced as rental for utilizing equipment. Their cost is their cost of making pig iron, plus the per ton royalty paid to the DPC. The latter, in most cases, runs from $3.00 to $4.00 a ton.

Reference is to huge steel corporations "whose plants have benefited from the addition of modern government-built low-cost producing facilities during the war."

Most of these facilities are still owned by the government, and the steel companies pay a royalty for using them. Steel companies are now trying to get higher steel prices because of increased costs.

Of the 20 small steel producers confronted with disaster, one is on the verge of suspending steel producing operations, another is operating at only 40 per cent, and several others are confronted with having to abandon operations before the war is won.

Apparently, WPB is powerless to expand civilian requirements at this time. Lower costs might not enable these companies to obtain any more business than they now have, but would better their financial position, even though not adding to actual operations. Ingot supplies are now more than plentiful and seem to be balanced with finishing facilities, under present restrictive WPB measures.

Reference is made that jobs of 27,000 wage earners are possibly endangered, due to the inability of these small firms to compete with larger companies.

Under present WPB restrictions, orders which might be shifted to other steel companies would still mean less man hours at the plant from where the orders were shifted.

Small companies, which had been granted price relief by OPA at above the ceiling price, are losing business now because material can be purchased elsewhere at the ceiling price. These companies have had to reduce their selling prices, or lose the business to huge steel corporations who can sell for ceiling prices.

The history of the steel industry has been that when supplies are in balance or in excess of demand, so called premium prices cannot be realized.

Reference is made that the employees of the 20 small producers have given the companies an annual wage subsidy of more than $4,000,000. The workers of these small producers have straight-time hourly earnings of 94c., compared with straight-time hourly earnings of the entire steel industry of $1.02 an hour.

This situation could result from the steel union either granting a lower basic rate to these companies than to the steel industry generally, or it could be due to a greater number of higher skilled workers in the industry than was proportionate in the small companies, or it could be due to both.

In submitting entire cost of production figures to the Small Steel Commission (one steel man, one government representative, labor representative), the participating producer must meet the following set of standards:

1. ***No executive officer shall receive total compensation that, after taxes, nets him more than $25,000 a year.***
2. ***Dividend payments to stockholders should not be above a reasonable level.***
3. ***All outstanding federal laws and regulations affecting labor shall be adhered to by the participating producer.***

1. None is believed to even reach this standard, but would like to.
2. All steel stockholders claim they have not reached a reasonable level.
3. The answer to this is obvious.

Smaller Midwest Companies Indicate Murray's Argument Errs

Chicago

• • • **Smaller** steel companies in this area named by Philip Murray as "confronted with disaster" because of a scrap shortage were not consulted before being taken under the CIO wing and moreover deny that any scrap shortage exists.

Most of the companies named by Murray depended chiefly upon low cost local scrap for sustenance before the war, and are using a larger proportion of pig iron in their overall melt than in the prewar period. However, the higher operating rate has to some extent offset the higher production costs engendered by the necessity for larger iron purchases. In recent months the scrap situation has become easier rather than more diffcult for most mills mentioned by Murray, and in no case have operations suffered for lack of scrap. The general trend now is toward an increasing scrap ratio in melting. The St. Louis area shared in recent scrap shipments from the West Coast but because of shipment on government bill of lading delivered costs were not excessive. It is emphasized universally that these shipments were not necessary to carry the mills through the winter. It is pointed out that shipments from the West Coast had the effect of bolstering the market there; yet Murray expressed concern for an independent mill there whose scrap costs must have been bolstered by these government shipments while inferentially endorsing them.

One independent mill named by Murray said that his statement had "aroused our curiosity" for its workers are represented by an independent rather than a CIO union.

Although a St. Louis mill recently was forced to shut down, other small midwestern mills show no signs of being on their last legs. In fact, indirect price concessions have been offered on wire product sales by two of the mills Murray mentions.

None of the mills named expressed eagerness for the plan proposed by Murray, pointing out that increased labor costs had been as great a factor in raising their overall production costs as had the cost of raw material. It was generally felt that an overall price increase would be more desirable.

• • • **Commenting** upon the Murray plan for small steel companies (THE IRON AGE, March 9, page 96) which included a proposal that the government should sell returned battlefield scrap to certain steel mills in order to make them more competitive with the larger producers of steel, Edwin C. Barringer, president and executive secretary of the Institute of Scrap Iron & Steel Inc., Washington, said:

"Whether the government subsidizes any steel mills is entirely a matter of government policy, but the scrap industry is concerned over the implication in Mr. Murray's statement that the mills he would have subsidized can no longer buy low cost scrap. . . . It is incorrect to state that any mill faces disaster because of a shortage of scrap, as some mills have been restricting their intake of scrap recently. . . . Returned battlefield scrap is only a fraction of 1 per cent of the total of open market scrap now being consumed, and certainly has no great influence on the supply problem. Whatever may be the merit of subsidizing one group of steel mills, the scrap industry regrets that it should be drawn into the picture and the supply situation distorted."

H. K. Porter Co. Buys Illinois Freight Car Firm

Pittsburgh

• • • **Entering the freight** car manufacturing field and greatly expanding its Process Equipment Division, H. K. Porter Co., Inc., Pittsburgh, has purchased Mt. Vernon Car Mfg. Co. and its subsidiary, J. P. Devine Mfg. Co., Inc., both with plants at Mt. Vernon, Ill.

Acquisition of Mt. Vernon Car Mfg. Co., representing approximately 10 per cent of the nation's freight car manufacturing capacity, is said to make Porter the largest independent in this industry. J. P. Devine Mfg. Co. is a maker of heavy chemical, food, and oil refinery equipment.

An active expansion program is planned for Mt. Vernon Car Mfg. Co., with new types, including a line of tank cars, being added to its present line of box cars, gondolas, refrigeration cars and cabooses.

LABOR GETS THE SUNSHINE: *Management and labor welcome Mrs. Roosevelt on her study of women in war industry as Packard president Geo. T. Christopher (left), and Norman Matthews (right), president of Packard Local 190, UAW-CIO, greet the first lady on her arrival recently at the Packard Motor Car Co.*

Navy Contract Termination Bill Introduced; Bars GAO Interference

• • • **Proposed** legislation which would give the Secretary of the Navy major authority in settlements of Navy war contracts was introduced in the House March 13.

Chairman Vinson (D., Ga.) of the House Naval Affairs Committee called it "the Navy Department's bill." He said his committee would start hearings on it this week with Navy officials the first witnesses.

The bill would authorize the Navy Department to make prompt and final settlements of claims on termination of its contracts. It would bar the general accounting office from Navy termination settlements except to determine whether fraud existed and whether payments to contractors carried out terms of agreements.

The Secretary could authorize interim payments to contractors or the government could guarantee private loans.

As to disposal of surplus property —a classification from which ships, aircraft and real estate would be specifically excluded—the Secretary would determine methods of selling with a view to avoiding glutting markets or promoting monopolies.

In establishing standards for settling claims, the bill would direct:

1. Full payment at contract price for all completed items accepted, cost of work done and materials acquired, less specified adjustments.

2. No costs would be allowed for expense of conversion to uses other than the performance of the contract of for losses except normal spoilage.

3. Claims would be barred unless filed with the Secretary within one year after the contract termination date unless the time was extended for not to exceed six months by the Secretary.

4. Contractors would be given 180 days in which to appeal decisions of the Navy negotiators to an appeals board established by the Secretary.

5. Settlements in excess of $50,000 would have to be approved by a settlement review board of three or more members named by the Secretary; those in excess of $500,000 would have to be approved by the chief of the settlement bureau, and those exceeding $1,000,000 by the Secretary of the Navy.

Appeals could be taken to courts as well.

90,000 Planes Made by Britain, Report Discloses

• • • **Britain** has produced more than 90,000 planes from the beginning of the war to the end of 1943, it was disclosed recently in a report by British Production Minister Oliver Lyttleton, who also gave hitherto secret figures of British war production. Combat type planes mainly were produced and naval construction, he said, has more than replaced losses.

The Production Minister said that from the beginning of the war to the end of 1943 "we have made for the army alone 83,000 tanks, armored cars and carriers; over 115,000 guns of cal. larger than 20 mm.; 150,000,000 rounds of gun ammunition; nearly 5,500,000 machine guns, rifles, submachine guns and automatic pistols and nearly 7,000,000,000 rounds of small arms ammunition."

Agricultural Machinery Programmed by U. N. R. R. A. for European Distribution

• • • Perhaps the most interesting thing about the proposed distribution of farm machinery to Europe, shown below, is that delivery of portions of this equipment was set for Aug. 1, 1944, according to Calvin Johnson, Illinois Congressman, who introduced these data before Congress. He says some of the equipment, which includes 13,000 tons of spare parts, is scheduled to be sent to areas where machinery of this kind never before has been seen. Later, Senator Reynolds of North Carolina, protested against the U.N.R.R.A. plans. Committees of both Houses indicated they would clamp down on the general plans.

"Patman to Maverick to Jones" Newest Play by Small Business Group

Washington

• • • The report of the Patman (House) Small Business Committee on surplus property can be described as a new all-Texas triple play of "Patman to Maverick to Jones."

Legislation recommended by the report would give: To Texan RFC chief Jesse Jones, the job of Will L. Clayton as Surplus Property Administrator; to Texan Smaller War Plants head, Maury (lame duck) Maverick, a place on the new Surplus Property Policy Board; to Texan House Small Business Committee chairman, Wright Patman, the political credit for sponsoring a bill which provides for the lease or sale on terms of war surpluses to returning service men.

While agreeing with the Baruch report in general, the Committee makes the following recommendations:

1—Studies should be made before sale of the government-owned plants as to possibilities of sub-dividing the very largest units to make them available for acquisition by small business.

2—An easement to the patent right covering the products manufactured in any government-owned plant during wartime shall accompany the sale of the plant or any parcel thereof when the plant and its manufacturing facilities have been established for some specialized manufacturing use.

3—Provision shall be made for the "temporary enjoining" of surplus sales through appeal to the Surplus Property Board in those cases where it may be held that the holding of such sales would prove detrimental to the best interests of any firm in the industry in question or where "large interests were apparently about to be given undue preference over small firms through the holding of such sales."

4—The patents and other properties now held by the Alien Property Custodian for which there is no obvious military use shall be declared surplus and transferred as to title to the central disposal agency and treated in the same manner as other surpluses.

The aims of the Committee are captured in the following summary:

"The House Committee on Small Business feels that the time has come for a careful review of all pending legislative proposals relating to surplus property disposal. It feels that such review should be taken not only in the light of the Baruch report and its accompanying executive action but especially from the viewpoint of the small businessman. The committee feels that it would be delinquent in its appointed duty at this time if it did not point out that it feels that much of the proposed legislation on this subject fails to provide adequate guarantees designed to protect the small businessman and assure him proper consideration in the disposal of these surpluses.

"Further, with not intended reflection on either the integrity or the ability of the one just appointed to the post of Surplus Property Administrator, the committee feels that it has not yet seen visible evidence that the Administrator has been provided with or has prepared any book of procedures designed to give adequate protection to small business. He is working under an implied mandate in the Baruch report which says, 'the Surplus Administrator should sell all he can as early as he can.' Much of the physical detail of selling is apparently still to be vested in some of those Federal agencies which have shown definite evidence of ineptness and disregard of small business interests in the past. The very magnitude of the problem precludes the personal supervision of all sales and their statements of justification by the Administrator."

ASU Chief Warns Against Unnecessary Changes in Forge Shop Schedules

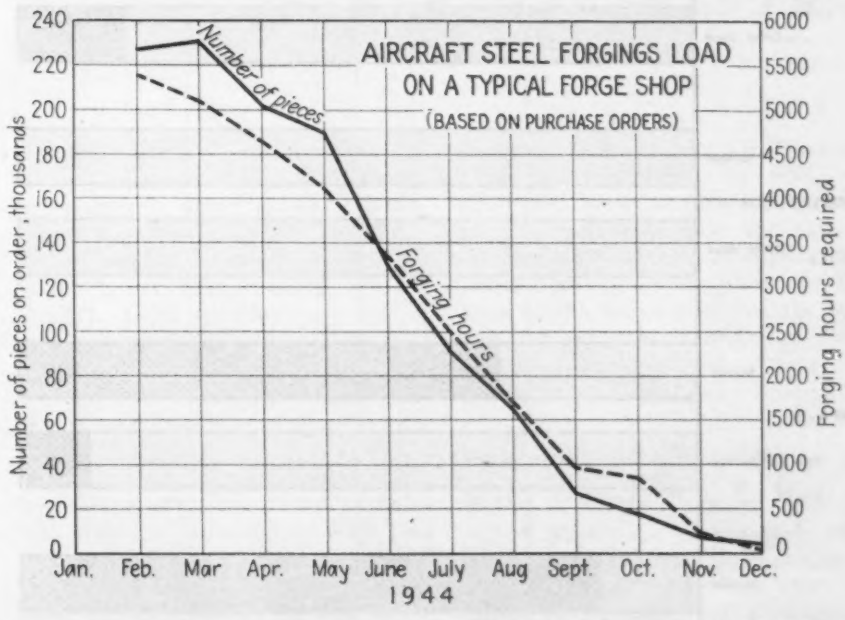
Dayton, Ohio

• • • **Satisfactory** delivery of aircraft steel forgings will become increasingly difficult to obtain unless aircraft manufacturers take steps to avoid unnecessary changes in forge shop schedules. This fact was emphasized by Col. E. W. Rawlings, Administrator of the Aircraft Scheduling Unit, in a recent interview.

Steel forging shops are being asked to break all existing production records during the coming months. This load is the result of substantial increases in various programs. Aircraft needs alone in 1944 will be up 33 per cent.

Manufacturers can take the following steps to forestall time-consuming changes in forge shop schedules, Col. Rawlings points out:

1. Extend purchase orders to the full extent of all contracts.
2. Indicate, wherever possible, what forgings will be needed beyond present contracts. (The accompanying load chart on an actual forging shop shows graphically the scheduling problems engendered by manufacturers' failure fully to extend their purchase requirements.)
3. Check—in the case of prime contractors—the ordering procedure of subcontractors.
4. Set up proper inventory and material controls for insurance that clerical errors do not cause changes in requirements.
5. Confirm all verbal instructions by letter.
6. Allow forge shops sufficient flow time.



• The scale units on this chart are in terms of "forging hours" and "number of pieces" in a typical forge shop and the scale unit on the aircraft steel forgings requirements chart is in net tons. The two cannot be compared directly, but the trends are comparable and show that immediate placement of aircraft steel forging orders to the full extent of all contracts is required if 1944 aircraft requirements are to be met.

Note: Chart is based upon Forgings for following planes:

A-20, A-30, A-35, B-17, B-24, B-25, B-26, B-29, B-32, C-47, F-6-F, F-7-F, J-2-F, P-38, P-40, P-47, P-51, P-61, PBM, PV-1, PV-2, PV-4, SB-2D, TBF, TBM

Even Broader Decentralization of Priority Applications Believed Likely

By D. C. MacDONALD
Cleveland Editor

• • • **A review** of the degree of decentralization of WPB authority to its field offices and a check of the attitude displayed by the field office representatives reveals not only that decentralization has progressed satisfactorily so far, but also that much broader decentralization is in view. Industry, which has long been handicapped with delays caused by the necessity to forward applications to Washington for various types of approval, now appears to have a bright outlook in broader authority of individual district and regional offices which have gained stature rapidly within the last year and promise to take on new powers from month to month.

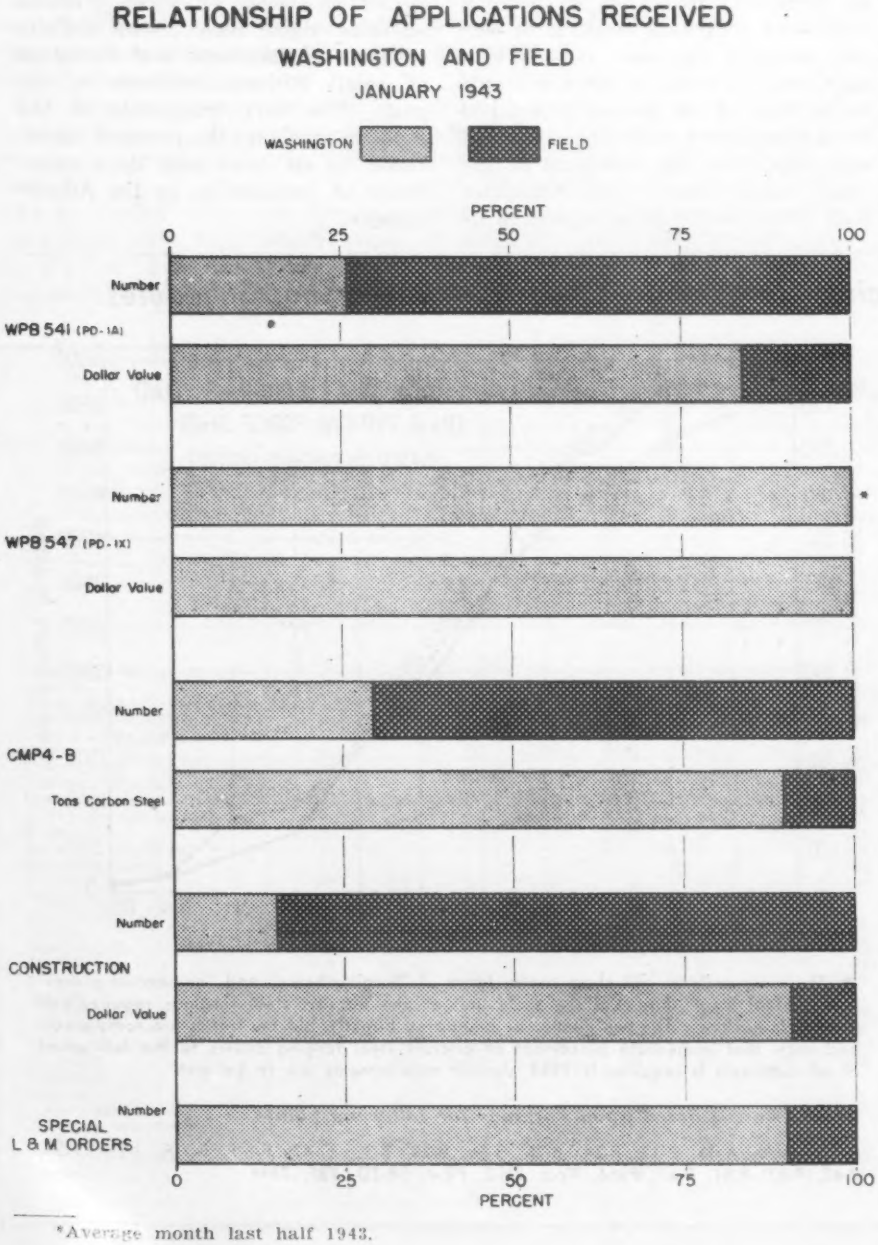
An analysis of the degree of decentralization which has been achieved by WPB since the planned inception in March of 1942, when the humble power to process PD-1-a applications valued up to $100 was permitted, reveals that the bulk of processing as measured by both number of applications and dollar volume still remained with Washington at the beginning of 1943. During 1943 many of the major decentralization steps have been taken. The continuing trend and aims of the field offices is toward an ever enlarging field of authority, a goal which seems likely of achievement and highly beneficial to industry.

As a measure of the balance between field offices and Washington receipt of all types of priority applications, WPB statistics show that during January, 1943 Washington received applications at the rate of 208,000 as compared with 84,000 at field offices. These figures include all types of applications.

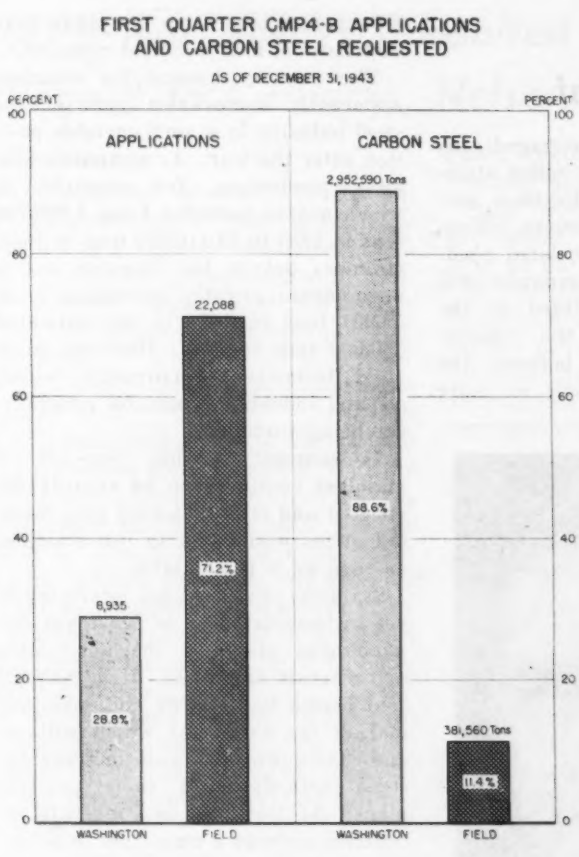
During this same month Washington was receiving and processing approximately 29 per cent of all PD-1-a applications totaling nearly 85 per cent of the dollar value, all of the PD-1-x applications, approximately 30 per cent of the CMP 4-b applications controlling at least 95 per cent of the carbon steel allotments on this form, about 18 per cent of the construction applications controlling 95 per cent of the dollar value and probably 90 per cent of the special applications applying to L and M orders.

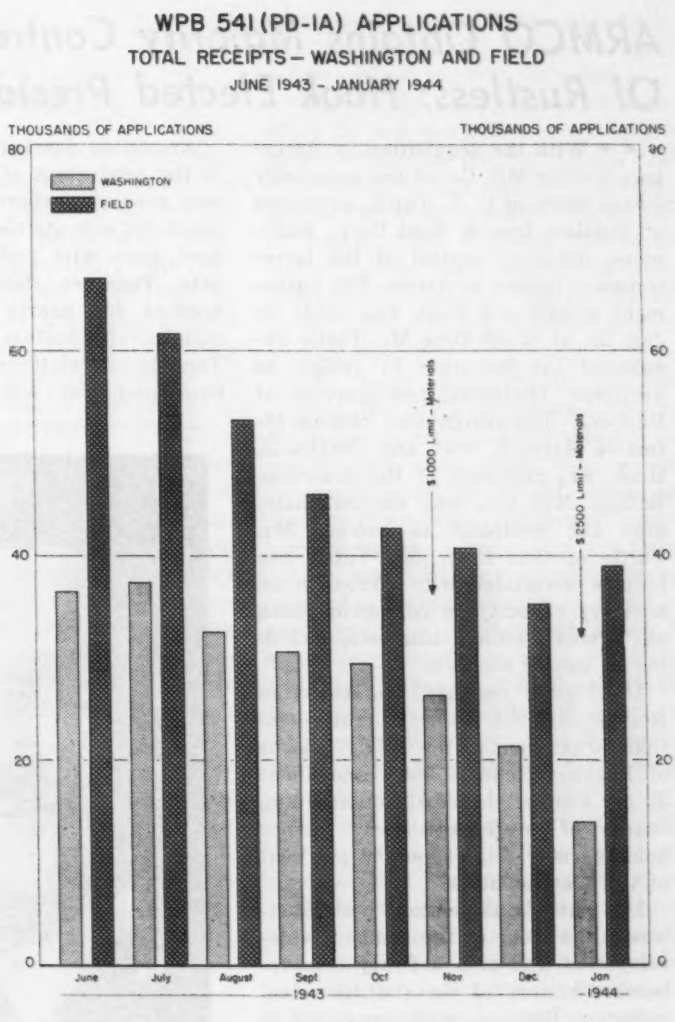
Although the general trend in the receipt of PD-1-a applications is generally predominantly downward, by January of 1944 the ratio between the two sources of receipt had changed to Washington receipts of only about 14,000 applications as compared with 39,000 applications by field offices during the month. At this point the limits of PD-1-a applications had been increased from $100 to $1000 and later to $2500, a limit which was in effect during January, 1944. Because of this low top limit on PD-1-a applications suitable for field application, the dollar value still overbalanced in favor of Washington for the month with a total of $118,000,000 processed at Washington as compared with about $21,000,000 processed in the field.

An estimate as to the possible effect of an increase to $25,000 as a top limit for field processing of the PD-1-a applications is estimated to change the ratio per month to about 400 cases valued at $59,000,000 for Washington compared with 52,600 cases valued at about $80,000,000 which would be processed in the field. A further value increase to $100,000, which is not considered unlikely, could boost the ratio to an all-time low of 70 applications per month at Washington totaling only $11,000,000,



*Average month last half 1943.





while nearly 53,000 cases valued as high as $128,000,000 could be processed in the field. Thus the aim and ultimate goal of the field offices for further decentralization are within reach if these limits can be increased.

First quarter CMP-4-b applications for carbon steel as of Dec. 31, 1943 show that 8935 or 28.8 per cent of the applications were handled by Washington. This, however, controlled 88.6 per cent or 2,952,590 tons of the carbon steel involved. Field processing of the applications, which handled 71.2 per cent or 22,088 applications, controlled only 11.4 per cent of the steel involved or 381,560 tons.

The report on PD-1-x applications indicates that approximately 33,000 applications per month are now being directed to Washington. All these, the field offices contend, could and should be processed in the field. However, it is pointed out that the field offices would favor a simplification of both the forms and the routine of processing before wishing to take on the task. Local rating would also be asked.

On construction permits Washington handles about 91 per cent by dollar volume but probably only 15 to 16 per cent by count.

Special applications applying to operations under the L and M orders are overwhelmingly handled by Washington in view of December, 1943 statistics recently revealed showing at least 90 per cent handling by the Capitol. Local estimates are that a ratio of about 96,000 in the field against 20,000 per month in Washington could be attained if decentralization is permitted to expand sufficiently during this year.

Summarizing the goals for decentralization which are being mentally established in the minds of WPB field offices the following aims are being set up: The limit on PD-1-a applications for field processing should be increased from the present $2500 to $25,000; PD-1-x which is considered essentially a local problem where decentralization would materially aid distribution for the wholesaler and retailer should be totally handled in the field; the limit on construction permits should be advanced to $100,000 except for increased production facilities in which Washington should take the lead; the handling of all war and non-war housing by NHA through FHA thus eliminating the WPB entirely and broad and distinct powers to pass on customary applications having to do with special applications under L and M orders. These are the aims of the field offices and the outlook for government controlled business.

Finished Steel Shipments Break Records at U. S. Steel

• • • **Shipments** of finished steel products by subsidiary companies of United States Steel Corp. for the month of February set a record at 1,755,772 net tons.

February shipments compare with 1,730,787 net tons in January, an increase of 24,985 net tons, and with 1,691,592 net tons in February, 1943. For the year 1944 to date, shipments have set a record at 3,486,559 net tons against 3,377,585 net tons in the comparable period of 1943, an increase of 108,974 net tons.

ARMCO Obtains Majority Control Of Rustless; Hook Elected President

• • • **With the acquisition** by American Rolling Mill Co. of the personally owned stock of C. E. Tuttle, president of Rustless Iron & Steel Corp., Baltimore, majority control of the latter company passed to Armco. The agreement to sell this stock was made on Jan. 28, at which time Mr. Tuttle announced his intention to resign as president, chairman, and director of Rustless. The resignation became effective March 6, 1944, and Charles R. Hook, Sr., president of the American Rolling Mill Co., was elected chairman and president to succeed Mr. Tuttle at that time. Mr. Tuttle has become associated with Armco in an advisory capacity in connection with all Armco stainless interests, including of course Rustless.

Until quite recently, the American Rolling Mill Co. owned slightly less than 50 per cent of the 926,547 shares of Rustless common stock and about 22 per cent of the 36,512 outstanding shares of preferred stock. Armco holdings now total about 60 per cent of the common stock.

Mr. Tuttle's association with Rustless is the story of the company's development and also a fairly comprehensive history of the stainless steel industry. Rustless, while organized in 1924, was non-operating for a number of years. Mr. Tuttle became associated with the company in 1929 and its president in 1930.

Rustless now accounts for nearly 25 per cent of the nation's annual stainless steels in the United States. With a national stainless steel output of about 430,000 tons in 1943, it can readily be observed that Rustless capacity of 114,000 tons played an important role in this record-breaking achievement.

As pointed out, Armco's interest in Rustless is not a new venture, Armco having made its original investment in 1935 and having owned a controlling interest since 1936. Armco representatives have predominated on the Rustless board of directors, but Rustless management has had complete freedom in the management of the company and execution of policies.

Mr. Hook indicated that aside from normal coordination of efforts of the two companies, no changes in the Rustless plans or policies are contemplated nor in the executive or managerial staffs of the organization except that of Mr. Hook assuming the post of president and chairman.

Armco at present is engaged only in the production of flat rolled stainless products, whereas Rustless produces for sale stainless ingots, billets, bars, rods, wire and associated products. Together, these companies will account for nearly a third of the stainless production in the country. The closer relationship between the two companies will result in more effective collaboration in production, distribution, and technical research.

CHARLES R. HOOK, SR., *president of American Rolling Mill Co., was elected president of Rustless at the March meeting of stockholders.*

C. E. TUTTLE, *president and chairman of Rustless Iron & Steel Corp., since 1930, resigned his posts but will remain in an advisory capacity with the company.*

The pent-up demand for stainless apparently leaves this part of the steel industry in a very enviable position after the war. As compared with alloy production, for example, in which output mounted from 1,805,748 tons in 1934 to 13,116,000 tons in 1943, stainless output has likewise had a phenomenal growth, increasing from 55,907 tons in 1934 to an estimated 430,000 tons in 1943. However, alloy steel demands are currently falling off and industry expansion programs are being curtailed.

In contrast to this, the use of stainless continues to be sharply restricted and it is indicated that many industries would like to use stainless as soon as it is available.

Stainless producers are interested in yet unformulated or at least yet unannounced plans of the automotive and aircraft industries. It is believed that herein lies a large and sustained market the extent of which will remain unknown until auto builders become articulate on their postwar plans. As the auto and aircraft industries undergo a transition to peacetime production, the metal manufacturing industries will likewise go back to making the grades and types of metals required by these industries. This transition will not prove difficult for steel producers, as a whole, but specifically Rustless has no serious reconversion problems because the products made for the war are the same as those made before the war and as will be required for peace.

An important contribution made by Mr. Tuttle has been in connection with the development of domestic supplies of chromium ore concentrates. Early in 1934 he undertook exploration of this country's chromite resources and personally financed the development and acquisition of certain properties. Later, Rustless Mining Corp. was formed and acquired Mr. Tuttle's interest in these developments. A mining and beneficiating plant has been in operation in northern California producing substantial quantities of higher grade material.

In 1939 an English subsidiary company was formed, the British Stainless Steel Co., Ltd. A plant site and some equipment were obtained to build this stainless plant in England, but plans were halted by the war.

If these plans had materialized, they would have made a vital contribution to the war effort because substantial quantities of stainless have been exported to England.

WPB Not Always Consulted in Regard to Cutbacks, Nelson Asserts

Washington

• • • Answers to questions affecting WPB's reconversion policy were made public by Donald M. Nelson on March 9. The questions were made in writing earlier in the week by Senator Francis Maloney, Democrat of Connecticut.

Highlights of Mr. Nelson's reply were:

Cancellations—"Up to the present the services have consulted WPB on cutbacks only to a limited extent. The following procedure is being put into effect: The military services determine their requirements and when our rate of production is in excess of requirements, they consult with WPB to determine the advisability of cutbacks in the program."

Cancellation Priority—"So far as possible we attempt to guide the cutbacks in the critical labor areas—to ease the manpower situation in these areas."

Civilian Production Timing—"The availability of manpower, materials and component parts determines the extent to which civilian production can be expanded in concerns whose military production has been cut back. The military services also are concerned over possible adverse effects of an expansion of civilian production at this time on morale both at home and among the fighting men abroad.

"With these factors in mind, our policy is to expand civilian production as it becomes possible to do so without interference with the overall war program, and particularly in concerns whose war orders have been cut back.

"The Office of Civilian Requirements has prepared a number of programs for expanded production of civilian items and has listed their relative order of importance to the economy.

"It is our purpose to put these programs into effect whenever the military outlook and the situation with respect to manpower, materials and parts indicates the advisability of such action."

Maintenance of prewar competitive status—"If without interference with the war effort, we can give a manufacturer in a non-critical manpower area materials and parts to resume production of things the civilian economy needs, I think it is to the public interest that we do so without waiting until another concern in a critical area is permitted to resume production. This policy may seem hard on the manufacturer in the critical area, but it would be at least an equal hardship on the manufacturer in the non-critical area if he were prevented from resuming production, just because a manufacturer in a critical area could not do so.

"Until that happy period when we can resume civilian production on a much broader scale than will be possible so long as direct military production must be maintained in large volume there will be many shortages of civilian products whose importance to the economy demands their production and scheduling with the same certainty as must be applied to war items.

"Repair and maintenance parts, supplies for the service industries and some consumer items whose depletion has left critical shortages in the life of the American household, must be assured production.

"The only way that I can see to do this is to fit them into production schedules wherever it is possible to do so, even though the effects on competitive situations may be painful.

"This is the same method that we apply to war production for military items, where we do not consult the convenience or the competitive interests of the firms involved. I can see no escape from applying the same method to the most essential civilian production so long as we are forced to meet the military requirements of a quick victory."

New Competition—"This question touches the roots of national policy. If the government were to attempt to prevent new competition, there would be clearly grave danger of shackling the country with a regimented economy for a long while to come. Such action would require detailed planning of all production by a government group, a development which I would strenuously oppose.

"In my judgment, it is all important to maintain a competitive economy. I do not believe you can have a democracy and at the same time forbid new competition.

"If with the return of peace, we were to start out with the policy of planning our peacetime economy in detail, as we would have to do to prevent new competition, we would do irreparable injury to the free enterprise system in the United States.

"Restrictions on 'new' companies which want to enter an industry for the first time will undoubtedly be needed until the now critical components and materials are in easy supply. Certainly so long as wartime controls are retained, materials and components should not be allocated to these 'new' firms until firms already established in the affected industries, and which are in position to resume production of their former products, have received their just allocations."

Relaxation of Controls—"It is my view that controls should be relaxed whenever they cease to be necessary to war production. However, the need for controls is obviously going to continue for some time.

"Even in the case of material which is in good supply today, if suddenly the controls were relaxed another shortage would be likely to occur, injuring production for war.

"As for component parts, I would estimate that in the consumer durable goods field there are 20 to 30 industries which require components which are now very critical, such as ball bearings, fractional horsepower motors, heavy castings and engines."

EYE SHIELD ADDED—*Rubber covered eye shields prevent U. S. tank gunners from getting black eyes while peering through telescopes in tanks rumbling over rough terrain. A Westinghouse worker at the Electric Appliance plant, Mansfield, Ohio, is pictured here attaching an eye shield to a three-power telescope.*

Specialty Scraps Sales Made at Prices Substantially Under Ceilings

• • • **Specialty steel scrap** is undergoing marked price deflation and in many areas the demand has dropped off completely, with no sales to amount to anything being made. Demand in virtually all categories of tool and stainless steel scrap, declining since late in the past Summer, is now at very low levels and prices in many cases are at fractions of official OPA ceilings that were standard a year ago. An analysis of open market quotations in the Midwest area substantiate these remarks.

The price of type 1 tool steel scrap is a good example. Ceiling price for solids is $1.80 per lb. of contained tungsten in this class, which embraces tool steels with 12 per cent minimum tungsten and 1 per cent maximum molybdenum. On this basis the ceiling price for 100 lb. of 18-4-1 tool steel scrap is $32.40. Actual sales in the market are at no more than 20c. per lb., or $20 per 100 lb. Type 2 solids, containing from 5 to 12 per cent tungsten, are obtaining about half of the official OPA ceiling of $1.60 per lb. of contained tungsten. Molybdenum tool steels are going for almost any offer.

Tool steel scrap experts explain the slackness in demand in that category by pointing out the immense volume of tool steel ordered in the early stages of the war and made up into blacks. Heavy stocks were thus accumulated at consumer points, and these were backed up by large stocks of bars in warehouses, which are said today to be at disproportionately high levels.

One reason for disinclination to stock up in the light of today's soft prices is the belief that as time goes on tool steels will be specified more and more directly in line with use. This, say scrap authorities in this field, makes indiscriminate stockpiling inadvisable, due to the possibility of continued lack of demand in many classes which might be accumulated. Also looked upon as a factor of some scope in the picture is the increasing importance of powdered metal parts production, which eliminates the need for machining and thereby reduces somewhat the cutting tool market.

Stainless steels scrap grades are also selling substantially under ceiling prices. Steel scrap of the 300 series of stainless, which cluster around a proportion of 18 per cent chromium and 8 per cent nickel, are off 50 to 60 per cent of their ceiling prices, which scale from $80 per gross ton upward. Some sellers report getting only 30 or 35 per cent of ceiling prices. Similarly poor conditions are manifested in the 400 series of stainless steels.

One reason for the weak price condition of stainless scrap is uncertainty as to what the automobile industry will do after the war in its choice of stainless specifications. In the absence of any conclusive information or theories along this line, practically no stockpiling is being done beyond the present substantial inventories.

February Ingot Output Totals 7,188,482 Tons

Production of Open Hearth, Bessemer and Electric Steel Ingots, and Steel for Castings. Source: American Iron & Steel Institute

Based on Reports by Companies which in 1942 made 98.3% of the Open Hearth, 100% of the Bessemer and 87.6% of the Electric Ingot and Steel for Castings Production

Note—The percentages of capacity operated in the first six months are calculated on weekly capacities of 1,518,621 net tons open hearth, 125,681 net tons Bessemer and 87,360 net tons electric ingots and steel for castings, total 1,731,662 net tons; based on annual capacities as of January 1, 1943, as follows: Open hearth, 79,180,880 net tons, Bessemer 6,553,000 net tons, electric 4,554,980 net tons. Beginning July 1, 1943, the percentages of capacity operated are calculated on weekly capacities of 1,531,789 net tons open hearth, 116,494 net tons Bessemer and 94,667 net tons electric ingots and steel for castings, total 1,742,950 net tons; based on annual capacities as follows: Open hearth 79,867,450 net tons, Bessemer 6,074,000 net tons, Electric 4,935,960 net tons.

Eastern Aircraft Firms Will Show Excess Material

• • • **Millions** of dollars worth of fabricated items, component parts and materials that have become excess inventories of large eastern aircraft manufacturers because of change in design of aircraft now being made for the armed forces will be offered for sale at an exhibition to be opened at the McAlpin Hotel in New York on Monday, March 27. The exhibition, in which the aircraft companies have joined voluntarily, is to be conducted under the auspices of the WPB New York Regional Office. It will continue two weeks, through April 8.

More than 5000 different items, covering aluminum, steel, copper, hardware, perishable tools, miscellaneous industrial supplies and materials, and component parts, will be exhibited in the booths and panels to be set up by the aircraft companies.

Completion of Republic Mill at South Chicago Reported Approved

• • • **It was learned** from authoritative sources here March 14 that Washington has approved completion of the 32-in. rolling mill of the South Chicago steel mill under construction by the Defense Plant Corp. for operation by Republic Steel Corp. N. E. Goetz, district manager, was unable to estimate the amount of money involved in the further construction but stated that this project would round out the plants rolling facilities. DPC officials are reported to have instructed James Stewart & Co., general contractors, who hold contracts for the bulk of the construction, to proceed with the work at once.

Construction of the Geneva structural mill also will be resumed. *See page 99.*

Construction of the plant had been ordered suspended early this year by WPB although the plant was then considered 90 per cent completed. Consideration is now reported being given by DPC to the completion of what little work may remain to be done after the present rolling mill project is completed.

The 36-in. and 44-in. mills are known to have been completed. The 32-in. mill will be completed with this project. The blast furnace is completed but awaits lighting and the coke ovens are lighted but not operating. Six of nine electric furnaces are in operating condition and part of them are in operation. Three other electric furnaces are believed to require only wiring. Operation of the plant by Republic Steel Corp. rather than purchase by some outside interest is definitely indicated.

•

Chicago

• • • **Upon completion** of the 32-in. bar mill the Republic plant will be ready to go into fully integrated operation. Some work remains to be done on the sintering and slag handling equipment, but this is insufficient to delay operations once the rolling mill is complete. It is unofficially estimated that the remaining construction now approved amounts to between three million and four million dollars.

Kaiser Made Member of WPB Steel Advisory Committee

Washington

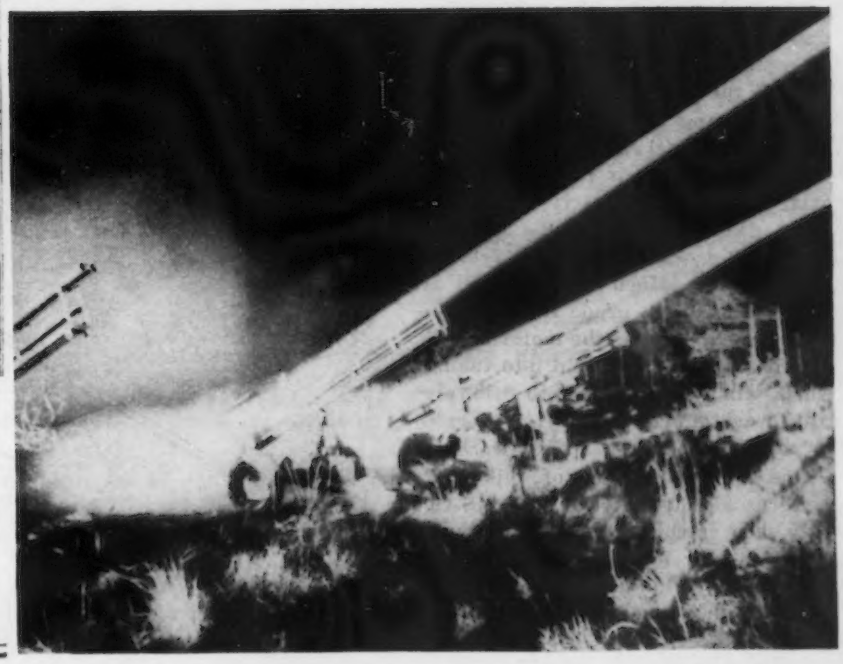
• • • **Henry J. Kaiser** was recently made a member of the WPB Steel Industry Advisory Committee, thus satisfying a demand of west coast interests who had insisted that the west coast steel industry was not adequately represented at board deliberations. However, it is reported that Mr. Kaiser, despite his appointment, is dissatisfied because other engagements will prevent his attendance at the next committee meeting on March 16.

Civilian Tractor Output Not to Be Increased in 1944

Washington

• • • **WPB reported** March 9 that there is little possibility of increasing civilian tractor production in 1944, according to reports given by members of the Tracklaying Tractor Industry Advisory Committee at its recent Washington meeting, although facilities are being prepared to increase production of one model for the Army.

The increased need for repair and spare parts for use by the military overseas was discussed and recommendations were made for assuring an adequate supply of parts for the armed services. Committee members recommended that military requirements by items be determined over a long-term period. The production cycle for parts, it was pointed out, runs from 9 to 12 months and military needs can be filled only if orders are placed far enough in advance to permit proper production scheduling.



ROCKET TARGETS: *A new angle for training anti-aircraft gunner is the rocket target. Above, the launching carriage that fires the targets is being loaded while the photo to the right shows the trail of the rockets traveling more than 450 miles an hr. through the night at Camp Davis, N. C.*

Cleveland and Chicago Share Heavily in New Shell Container Project

Cleveland

• • • **The facts** of the Ordnance Department container program, which has been credited generally with requiring enormous amounts of sheet, came to light March 8 when the collective evidence of several authoritative sources revealed that the prime contracts were let already in the majority of cases, that steel was being ordered and that production soon would be under way.

It has been disclosed that most of the production may center about the Cleveland and Chicago areas, with four sizes of a tubular sheil container being made locally and at least four additional sizes, of a different type, to be made in and around Chicago.

The four sizes to be made in Cleveland will hold 57, 81, 90 and 105 mm. shells and will be tubular in shape. (See illustration). The 57 and 81 mm. sizes will use 4-in. o.d. tubes welded from 16 gage sheet; the 90 mm. container will use a 5½-in. o.d. tube welded from 14 gage sheet and the 105 mm. container will use a 6-in. o.d. 14 gage sheet tube. Some 10 gage and 12 gage sheet is also required by the program for caps and components. Also, a few screw machine products.

Steel specifications are calling for either hot rolled or cold rolled sheet of SAE 1010 or 1020 grades with little or no preference being shown between either finishes or grades, since rush delivery is the foremost consideration. It has been learned on good authority in this connection that the entire container program is scheduled for completion in the first half of the year.

One of the most interesting features of the steel supply in connection with the program is that due to the extreme urgency of early delivery, a great deal of so-called idle and excess steel is expected to be pressed into service. Much of this steel is not of the exact grade or gage required but so long as the material will re-process, form and weld into tubing which will withstand a 2 to 3 lb. air test, every effort is going to be made to absorb this stock.

One known instance of this kind concerns a 1000 ton lot of 8 gage SAE 1025 sheet in coils which is being held by a mill due to a cancellation after processing. This is expected to be rolled to one of the lighter gages required and utilized.

Despite previous estimates of vast tonnages of sheet which would enter into the program, it appears now that approximately 70,000 to 75,000 tons will be used in the Cleveland district's share of the national program. All of this tonnage will be for sheet with the exception of a small amount in bars which will go into certain small screw machine products used with the containers.

Estimates of the sheet tonnage required nationally by the container program are said to exceed by 35 per cent the sheet requirements of the entire automotive industry for the comparable quarter of its best peacetime year.

It is interesting to note that the 6-in. tubing that will be required for the 105 mm. shell cases alone in this area would lay a pipeline approximately 1732 miles in length. About 2763 miles of tubing of all sizes will be used on the area's contracts. The tubing sizes up to 6 in. will be furnished by the steel producers ready for the prime contractors. The 6-in. size, however, is too large for this capacity and is being produced by five sheet metal fabricators in the district.

A check of the steel sources supplying the program indicates that smaller mills not closely tied in with the plate production facilities of the nation are being most heavily relied upon.

Steel orders from this region are reported being placed with American Rolling Mill Co., Weirton Steel Co., Ford Motor Co., Griffin Steel Co., and McLouth Steel Co. in as large quantities as possible with proportionately lesser amounts to Youngstown Sheet & Tube Co., Bethlehem Steel Co., and Jones & Laughlin Steel Corp. All orders are understood being placed in the form of the top urgency rolling directives requiring almost immediate delivery.

•

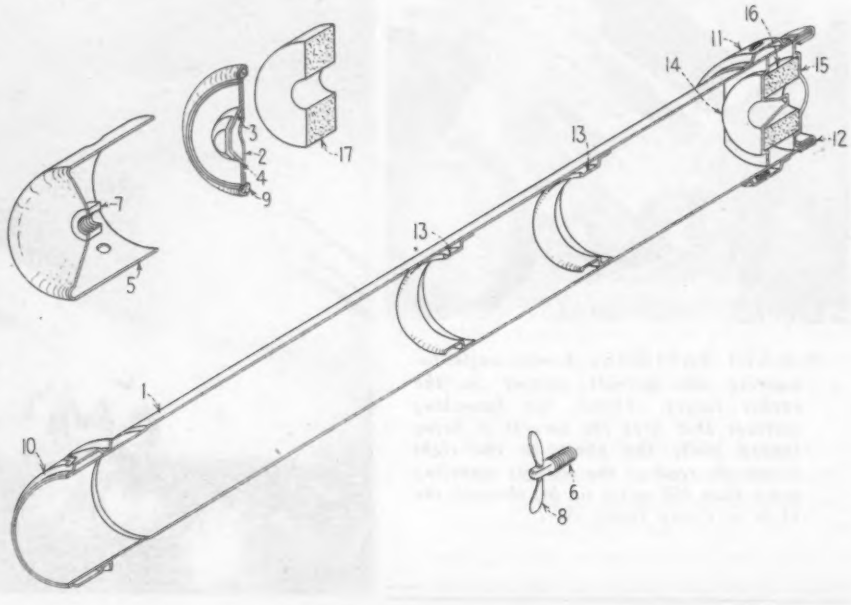
Screw Machine Products Advisory Committee Formed

Washington

• • • **The WPB Office** of Industry Advisory Committees on March 9 announced the formation of the Screw Machine Products Industry Advisory Committee. O. F. Fancey, of the Building Materials Division, is the government presiding officer. The membership is as follows:

Robert Chestnut, Aluminum Co. of America, Edgewater, N. J.; C. P. Dewey, American Screw Products Co., Indianapolis; J. S. Elsby, Screw Machine Products Co., Milwaukee; W. J. Finn, Chicago Screw Co., Chicago; Paul M. Hershey, Hershey Metal Products Co., Derby, Conn.; N. A. Hewitt, the Couche-Uthe Co., Elyria, Ohio; Charles H. Hyde, David Bell Co., Buffalo; W. C. Knight, Knight Screw Products Co., Inc., Detroit; Robert Olson, Olson Mfg. Co., Worcester, Mass.; Ernest W. Schneider, Hudson Screw Products Co., Inc., Chicago; Earl W. Stewart, Federal Screw Works, Detroit; Jesse Robbins, Arpee Products Co., Glendale, Cal., and T. A. Dear, Automatic Screw Machine Co., Los Angeles.

THIS DRAWING *is an isometric view of the new all steel water-tight shell container being produced for the Ordnance Department on the double quick. This is the 75 mm. size container of the tubular type constructed with welded tubing formed from sheet. Certain inaccuracies in the drawing are for the enemy's benefit.*



Foundry Will Study Price Order At Rallies in Boston and New York

• • • **Problems** of the gray iron castings industry, wartime and postwar, will be discussed by eastern foundry executives and many from the east north-central states, at one-day management-marketing conferences, sponsored by the Gray Iron Founders Society and endorsed by eastern groups, to be held at Hotel Statler in Boston March 22 and at Hotel Pennsylvania in New York City March 24. Executives of more than 1400 gray iron foundries have been invited, according to W. W. Rose, executive vice-president of the society.

Both conferences will focus attention sharply on the six recent changes in the provisions of the order governing maximum prices of gray iron castings with an analysis from both government and industry viewpoints. W. W. Welfling, new chief of the gray iron and malleable castings section of the OPA will review and interpret the amendments, designed, according to the agency, "to strengthen and clarify the ceilings and aid in their enforcement."

Industry discussion of the price order and its amendment will be opened at the Boston meeting by A. B. Root, vice-president of Hunt-Spiller Mfg. Corp., South Boston, and at the New York conference, by H. L. Edinger, president of the Barnett Foundry & Machine Co., Irvington, N. J. Mr. Edinger, vice president of the society, is chairman of the recently appointed gray iron castings industry advisory committee of OPA, and Mr. Root, a director of the society, is a member of the advisory group.

Principal speaker at the complimentary luncheon session of the Boston meeting will be J. H. Van Deventer, president and editor of THE IRON AGE, whose subject is the future of the foundry industry. Sights will also be set on postwar potentials at the New England gathering by H. B. McCoy, chief of the industrial economy division of the Department of Commerce, who will discuss after-the-war markets.

Luncheon speaker on the New York program will be Brig. Gen. William C. Rose, chief, executive services, War Manpower Commission.

o o o

Court Action Hits At Hillman Interest In National Supply

Pittsburgh

• • • **National Supply Co.** and Morgan B. Schiller, holder of 1950 shares of National Supply stock, have entered suit in a Federal Court at Pittsburgh, in an effort to separate Hillman interests from the National Supply Co.

The suit demands that Pittsburgh Steel Co. and Pennsylvania Industries, Inc., divest themselves of stock interests in the National Supply, and that J. H. Hillman, Jr., be enjoined from holding simultaneous directorates in the company.

The action, it was said, was filed under sections 7 and 8 of the Clayton Act and the Sherman Anti-Trust Law. Section 8 of the Clayton Act prohibits an individual from serving as a director of two companies, where one has a capitalization of more than a million dollars.

The suit asks that Pittsburgh Steel be enjoined from acquiring stock of National Supply as long as both companies remain in competition. Both companies are large manufacturers of steel pipe and tubular products.

Mr. Hillman is a director of National Supply and Pittsburgh Steel, and is president and a director of Pennsylvania Industries. He is also a director or an officer of many other companies, including Pittsburgh Coke & Iron, Hillman Coal & Coke, Pittsburgh Steel Foundry, First National Bank, and Alan Wood Steel Co.

The court was asked, also, to prevent Pittsburgh Steel and Pennsylvania Industries, pending any divestment of their stock interests in National Supply, from voting their present stock holdings.

This particular suit, it is said in financial circles here, brings to the surface differences of opinion which have existed between the principals for some time.

Price Briefs

• Amdt. 5 to MPR 314 places magnesium powder, magnesium dust, and similar magnesium materials under coverage of the order which provides ceiling prices for magnesium and magnesium alloy ingot. (Release No. OPA-T-1805)

• Amdt. 102 to SR 14 provides specific dollars-and-cents prices for sales to retail dealers and sales at retail by all sellers of approximately 4700 specially-built motorcycles, which the U. S. government will initially sell as surplus commodities. (Release No. OPA-4026)

• Amdt. 2 to MPR 465 adds all vessels listed to the provisions of the regulation setting maximum prices for used storage vessels which allows sellers to charge a portion of the original installation cost when in excess of $100. (Release No. OPA-T-1812)

• Amdt. 11 to RPS 41 establishes ceiling prices for magnaflux and radiographic inspection of steel castings. (Release No. OPA-T-1800)

OPA Railroad Specialties Advisory Committee Formed

Washington

• • • **Appointment of an** Industry Advisory Committee on Railroad Specialties was announced by OPA. Railroad specialties are such items as side frames, bolsters, couplers, and yokes used in the construction of railway cars. The committee is composed of eight steel castings company executives whose concerns together turn out 98 per cent of all railroad specialties.

Members of the committee are:

Frank Cordes, president, Pittsburgh Steel Foundry Corp., Glassport, Pa.; George T. Johnson, vice-president, Buckeye Steel Casting Co., Columbus, Ohio; George E. Scott, vice-president, Scullin Steel Co., St. Louis; James Suttie, vice-president, American Steel Foundries, Chicago; Harold Dunbar, vice-president, McConway and Torley Corp., Pittsburgh; J. A. Sauer, vice-president, Symington Gould Corp., Buffalo; James A. Slater, vice-president, National Malleable and Steel Castings Co., Cleveland; and Russell A. Cannon, vice-president, Birdsboro Steel Foundry and Machine Co., Birdsboro, Pa.

OPA Sets Price Ceiling On Stamped Metal Parts

Washington

• • • **Metal stampings** have been added to the list of articles covered by the regulation establishing maximum prices for machines and parts and machinery services. This OPA action, which becomes effective March 18, 1944, will simplify the determination of maximum prices by the industry by placing all stampings under coverage of a single regulation. Formerly, three price regulations applied to different types of metal stampings. The transfer will mean no change in prices. This action is incorporated in amendment 110 to MPR No. 136.

Indium Prices Reduced

• • • **The Indium Corp.** of America, New York, announced the following price adjustments, effective March 11, 1944.

	Per Troy Oz.
Electrolytic grade (high purity) indium	$12.50
Commercial grade (99.9 per cent indium	7.50
Indium trichloride	4.40

Other indium products are reduced proportionately.

Bearing Production Is Concentrated

• • • **To attain** greater efficiency and save manhours in the production of the larger sizes of anti-friction bearings used in heavy military and industrial equipment, WPB has concentrated production of many sizes in the heavy series of ball bearings in the plants of 10 producers. These producers will manufacture single-row, double E row and angular contact series ball bearings. Authorization was granted by the addition to schedule A of L-145.

The authorized producers for one or more of the specified additional bearing sizes are the Marlin-Rockwell Corp., Jamestown, N. Y.; SKF Industries, Inc., Philadelphia; Fafnir Bearing Co., New Britain, Conn.; New Departure division of General Motors Corp., Bristol, Conn.; Hoover Ball and Bearing Co., Ann Arbor, Mich.; Norma-Hoffmann Bearings Corp., Stamford, Conn.; Bearings Co. of America, Lancaster, Pa.; Torrington Co., Bantam Division of South Bend, Ind.; Ahlberg Bearing Co., Chicago, and McGill Mfg. Co., Valparaiso, Ind.

WPB Boiler Specifications Altered to Save Steel

Washington

• • • **Restrictions on** specifications for power boilers that may be produced were brought up to date by WPB by amending limitation order L-299. The amended order provides that no person shall produce, fabricate, or deliver any power boiler (except boilers for locomotives, marine service, or miniature boilers) having a greater metal thickness or quantity of steel than needed to meet the minimum thickness requirements of section I (Edition 1943) of the American Society of Mechanical Engineers Boiler Construction Code, and Addenda and Interpretations (including Case 968) issued prior to Jan. 15, 1944.

The restrictions previously were based on the 1940 edition of the ASME Boiler Construction Code and Addenda and Interpretations issued prior to July 1, 1943, the date order L-299 was issued. Case 968 defines the safety factor required in the design of power boilers. Exceptions to production and delivery restrictions are continued unchanged in the amended order.

WPB Pipe Specifications Conform with ASTM

Washington

• • • **Specifications for the** manufacture of steel pressure pipe have been modified by WPB to bring them into conformity with recent changes in basic pressure pipe specifications. These changes are made in an amendment to schedule 11 of the limitation order L-211. This order contains the specifications for steel pressure pipe which in turn are based on specifications established by the American Society for Testing Materials. The ASTM recently amended the basic specifications upon which L-211 standards are based, and, consequently, the order has been amended to bring it up to date.

The permissible specifications for steel pressure pipe for general and government use are shown in the amended order, along with the titles of these specifications. Also included with the order is a table of steel pressure pipe sizes permissible for general use.

Idle Government Owned Tool Study Planned by WPB

Detroit

• • • **WPB announced** here last weekend a new plan to make fuller use of idle government-owned machine tools. All equipment worth $500 or more that is "idle" must henceforth be reported every 30 days, starting April 1, on a new WPB form 3475. Idle, for purposes of this report, applies to any tool not working on government jobs or which is not scheduled for work within 30 days. This definition would make machines idle that are at work on civilian goods or farm implements, however essential they might be considered.

WPB regional and main offices will study this information to determine whether idle equipment is such that existing available contracts might be put into the plants housing the unused equipment. That failing, efforts will be made to pair up the excess equipment with requirements for those specific facilities. WPB officials emphasized that they had no intention of going on a "tool grabbing spree," and pointed to the fact that contracting war agencies must give their permission before any plant moves out any of their facilities.

The order does not apply to privately-owned machine tools.

Firth Sterling Reduces Carbide Tool Prices

McKeesport, Pa.

• • • **Firth-Sterling** Steel Co., announced that effective March 1, 1944, the special 10 per cent war discount that has been part of the company's price plan would be discontinued. Prices for Firthite sintered carbides will be based on new lists that the company released. These lists are more than 10 per cent lower than the lists upon which the war discount applied. Quantity discount allowed on the new list is 5 per cent of the carbide value.

Priority Changes

L-41—Dir. 3 provides that blanket authorizations used to permit owners of substantial industrial and commercial establishments to carry on miscellaneous routing construction during a fixed period, will no longer be issued generally. (3-6-44)

L-79—Dir. 1 rules that AA-3 rated orders for plumbing, heating, and cooking equipment placed prior to Jan. 15, will take precedence over lower rated orders which have been rerated AA-3. (3-7-44)

L-107—Sched. I, as amended, further eases restriction on the manufacture of extended surface heating equipment although in the main the former limitations will remain. (3-7-44)

L-126—Sched. II which provided specifications for refrigeration condensing units for industrial and commercial refrigeration, and air conditioning machinery and equipment, has been revoked. Prohibition on the use of steel in the construction of bases for refrigeration condensing units having over 20 h.p. motors has also been removed. (3-10-44)

L-145-a—Sched. A provides a list of sizes in the heavy series of ball bearings with the names of authorized producers of these items. (3-11-44)

L-157—Amended order permits alloy steel to be used in the manufacture of hand tools and other items covered by Sched. I, II, IV, and V. (3-10-44)

L-182—Amended commercial cooking, and food and plate warming equipment order makes several minor clarification changes. (3-11-44)

L-192—Amended order eases restrictions on construction machinery repair parts. (3-7-44)

L-211—Amended Sched. II modifies specifications for the manufacture of steel-pressure pipe to bring them into conformity with recent ASTM changes. (3-11-44)

L-248—Amended commercial dishwasher order makes several minor clarification changes. (3-11-44)

L-292—Amended order permits resumption of limited production of brewery and winery machinery and equipment. Dairy machinery quotas have been shifted and other food processing equipment restrictions are eased. (3-11-44)

L-299—Amended order changes specifications on metal thickness of power boilers to conform with ASME Code. (3-10-44)

M-11-b—Amended order adds a number of items to list of exceptions to limitations on the use of zinc imposed by the order. (3-9-44)

P-43—Amended order clarifies conditions under which priority assistance is given laboratories. (3-6-44)

Kearney & Trecker *Presents...*

the new 50 H. P.

*C. S. M. *Milwaukee*

EXPRESSLY DESIGNED FOR

Negative Angle MILLING!

If you've been looking for a milling machine that's big and rugged, with plenty of POWER — a machine that can take it — the 50 H.P. — C.S.M. was made-to-order for you.

This machine was designed and specially engineered to do *Carbide Steel Milling, but because it's an all-purpose machine, it will handle your regular milling jobs to perfection.

TOPS FOR *Negative Angle* MILLING

For the past year this machine has been handling all of the "Negative Angle" milling jobs in our own plants. If you have a Negative Angle milling problem, we believe this is the machine you need.

NOTE: Our Research Department will gladly help you with problems concerning Negative Angle milling. We invite your inquiries. Write Department C.S.M., Kearney & Trecker Corporation, Milwaukee 14, Wisconsin.

KEARNEY & TRECKER CORPORATION

C.S.M. FEATURES

- ★ 50 H.P. motor
- ★ Impact eliminating flywheel
- ★ Spindle speeds from 50 to 1250
- ★ Feeds — ¼" to 60"
- ★ Electric spindle brake
- ★ Available in both Horizontal and Vertical models

Purchase Orders Frozen by WP

Washington

• • • Purchase orders which hav been frozen under the provisions Priorities Regulation 18 remain fr zen in the delivery sequence that established for them regardless of t fact that order M-293 has been mod fied. The same rule applies to d liveries of Class Y products for whic purchase authorization has bee granted by WPB. Class Y produc are those components and parts ove which WPB exercises purchase orde control. Persons desiring to purchas such products are required to obtai specific authorization from WPB t replace orders for them and for pro ducers of such products to accept suc orders.

A product which has been froze under PR18 remains a part of a fro zen schedule despite the fact that th product itself may be removed fro control of the order under which i originally became a part of the froze delivery schedule. These rules ar explained in Direction 1 to Genera Scheduling Order M-293.

At the same time, WPB announce with the issuance of Direction 2 t order M-293, that the tables appende to it will remain in effect under th amended procedure until such time a they are revised to conform to th new rules. However, the Direction indicates that products which have been Class Z will become unclassifie products for the purpose of the amend ed regulation. This change is in lin with the elimination of the Class Z product procedure from the schedul ing order.

The Class Z product procedure was designed to require users of certain components and parts in products, which in turn were to be used in specific end products for specific claimant agencies, to indicate realistic

★ cutting down time today . . .

—means cutting down costs tomorrow!

Today, time is the world's most valuable commodity. Every time a plane is finished . . . every time a tank is turned out . . . we shorten the time between now and "V" Day.

And time will still be vital in the post-war industrial world. Production facilities will be tremendous. Sales will flow to those plants which can produce at low cost.

Here at Acme, our staff engineers are trained to save time for you today and cut costs for you tomorrow. Do you need a special tool? Acme can design and build it. Is there a problem in your production line? Acme engineers may have the answer to that problem.

Acme products, Acme engineers have helped many metal-working manufacturers with their production problems. Why not see what we can do for you?

delivery requirements on their purchase orders for such components and parts. This was accomplished by a vertical chain of reporting delivery requirements to the claimant agency concerned with the end product programs.

Unclassified products are certain components and parts manufactured by an industry only part of the output of which is subject to scheduling procedure. The plants which are subject to the scheduling procedure are notified by WPB.

Direction 2 also provides that where a manufacturer has, in the past, filed a form for Class X products, he may continue to file the same form in the future for those purchase orders already reported, despite the fact that the required reporting form may be changed by order M-293.

Class X products are those critical components and parts on which WPB requires manufacturers to file monthly order boards showing proposed delivery sequences. When these monthly reports are filed, the delivery sequence becomes a frozen delivery schedule.

Cancellation of Tungsten Contracts Brings Protests

Washington

• • • **WPB's order that** Metals Reserve Co. cancel domestic "eligible producer" tungsten contracts as of March 31 was attacked on March 7 by Senator James E. Murray of Montana, chairman of the Senate Small Business Committee and Senator James G. Scrugham of Nevada.

Under one option, the tungsten producer has the choice of continuing to sell to Metals Reserve at $30 per unit for 60 days and at $24 for a further 60 days, or until June 30. Thus, Senators Murray and Scrugham said, tungsten prices will not parachute as rapidly as mercury prices did immediately subsequent to cancellation.

"The net result will be, however, that after July 1, 1944, the bottom will drop out of the domestic tungsten market and prices will doubtless fall to the foreign level unless Metals Reserve continues to support the $24 price thereafter," said a joint statement issued by the Senators.

"Elimination of the $30 per unit price will close up most of our tungsten mines. If the price falls much below $24, it is likely that the handful of major producers will have to fold up as well."

Disposing of Work In Process Jigs, Delay Termination

New York

• • • **In addressing** the American Management Association at its Financial Management Conference on March 2, J. Tyson Stokes, vice president of Baldwin Locomotive Works analyzed the settlement of termination claims, particularly those of subcontractors. He pointed out that the prime source of delay is in the matter of disposing of work in process, completed but excess component parts, and such production aids as jigs, tools, and fixtures. The Baruch-Hancock report, the George-Murray Bill (S. 1370), Executive Order 9425 of the Surplus War Property Administration, and the appointment of William J. Clayton as administrator are attempts to solve the termination problem. Mr. Stokes' discussion dealt mainly with the matter of delays in contract termination, including the following remarks in his analysis.

Nearly every claim for reimburse-

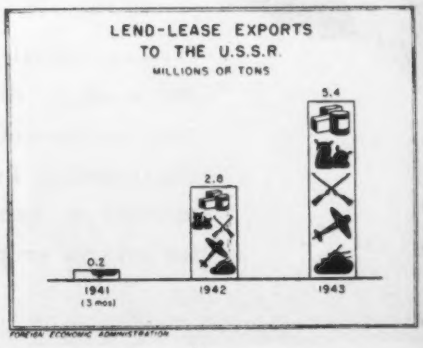
ment of termination charges and expense will, regardless of the method of computation, involve the element of value of special tooling expense, uncompleted work in process, excess components or all three. The percentage varies, depending on the nature of the work performed and the status of performance at the time of receipt of notice of termination, but it is not unusual for 50 to 75 per cent of the total cancellation claim in dollars to be represented by the value of this type of material.

Assume, for example, that the termination claim of a sub-contractor is $10,000 of which $6000 is attributable to the cost of work in process and excess material on hand; that the claim has been processed by all of the parties in interest including the contracting officer representing the government; and that it has been approved as eminently fair, just, and reasonable. To make the example a particularly good case, assume that the sub-contractor has waived all profit and has eliminated certain doubtful items in the hope that by so doing he will be promptly reimbursed.

There would seem to be no reason why this claim should not be paid promptly and in full. This, however, cannot be done without substantial risk to the prime contractor, largely because one fundamental and historic principle of governmental procurement, is "what the government pays for directly or indirectly it must own." Also, this hypothetical case is but one of hundreds of similar ones which will be presented to the prime contractor if a large prime contract is involved. If the prime finally settles and pays $10,000 to the sub while this material is still in the sub's possession and control and if the prime intends to include this disbursement in the prime's claim against the government, the prime will be obliged to account to the government for the



his versatile 250 KVP Jib Crane X-Ray Unit, er presents a soundly engineered apparabased on exhaustive study of the heavyy radiographic requirements of many dise industries.

wide scope of operational efficiency proes comprehensive radiographic facilities ending over a vast spread of materials d section thicknesses, from light alloys to " steel (with screens).

PX

This is the Picker 250 KV self-contained transformer-tubehead. Sixty-four years of experience in the manufacture of high voltage apparatus have gone into its design, which incorporates the following outstanding features:

1 **SELF CONTAINED.** Rayproof X-Ray tube and transformer oil-immersed in sealed, shockproof tank.

2 **NO EXTERNAL HIGH TENSION CABLES.** Improved Picker design eliminates need for high tension leads through U. S. Patent No. 1,334,936.

3 **LOW INHERENT FILTRATION.** Assures increased radiation output.

4 **FLEXIBILITY.** Trunnion-mounted tubehead swings freely in all planes, permitting universal angular positioning.

5 **CONTINUOUS OPERATING CYCLE.** Continuous operation at 15 milliamperes.

6 **HIGH EFFICIENCY COOLING.** Circulating oil pressure system requires no outside water supply.

7 **POSITIVE POSITIONING.** Jib boom is raised or lowered with positive control, by motor-driven chain hoist. Entire assembly locks firmly at any angulation.

8 **WIDE OUTPUT RANGE.** Output range from 30 KV to 250 KVP, with time voltage control, is adapted to radiography of variety of materials, from light alloys to heavy steels.

9 **INSTANT TUBE ACCESSIBILITY.** X-Ray tube is readily accessible for examination or replacement by simply removing special leak-proof access cover. No time-consuming disassembly necessary; no operational tieups required.

STEEL FOR DUCTILITY PLUS STRENGTH

Assembling airfield landing mats—clips made of Thomastrip have ductility, strength, and uniformity for high speed production.

Thomas Strip

COLD ROLLED STRIP STEEL

FOR UNIFORM QUALITY

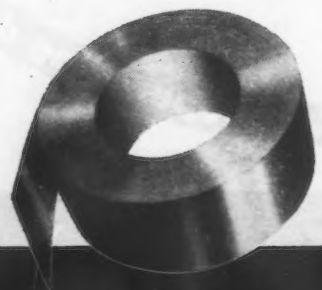
● The combination of ductility and strength found in steel makes it a most logical answer to many design and production problems. Since Thomas cold rolling, subsequent operations, and inspection are executed with great care, you'll find that Thomas adds uniformity, finish, and other product qualities to those other benefits which are inherent in the steel itself.

A few Thomastrip features are:

(1) accuracy to gauge
(2) finishes for painting and plating
(3) uniform tempers from dead soft to hard
(4) non-ferrous and lacquer finishes

Investigate with Thomas engineers the possibility of improving your product and reducing your production costs with Thomastrip. We will gladly send you a book "Classification of Extras—Cold Rolled Strip Steel." Write today.

BRIGHT FINISH NOT COATED, SOLDER COATED, ELECTRO-COATED WITH NICKEL, ZINC, COPPER, BRASS, AND LACQUER COATED—IN COLORS



THE THOMAS STEEL CO. • WARREN, OHIO

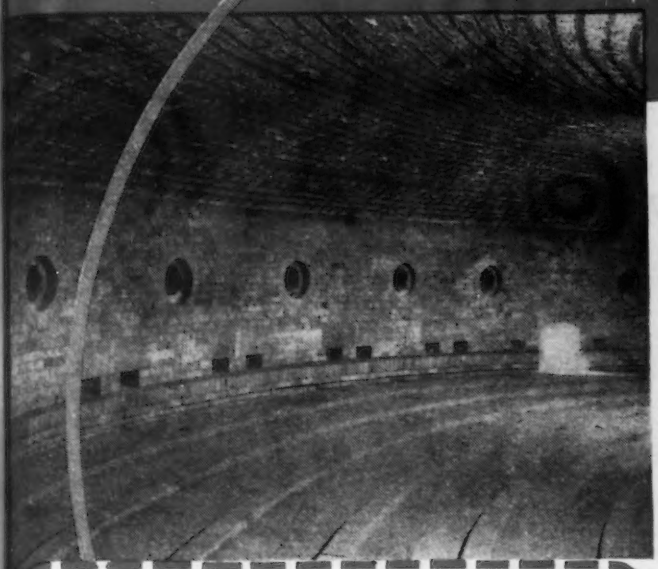
material and to have it available for delivery to the government on demand. If, as is often the case, the excess material is located a thousand miles or more away from the prime contractor's plant, there is no practical way for the prime to inspect it or to check the actual quantities with the inventory submitted. In a busy plant still engaged in war production, material of this type is easily lost, destroyed, or otherwise disposed of, assuming the best of good faith and orderly control on the part of the sub-contractor. The risk to the prime contractor is therefore apparent since if the material is not in fact available for any number of reasons several months after the claim has been settled and the sub-contractor paid in full, the government will refuse to reimburse the prime contractor for so much of his claim as is represented by the value of this material.

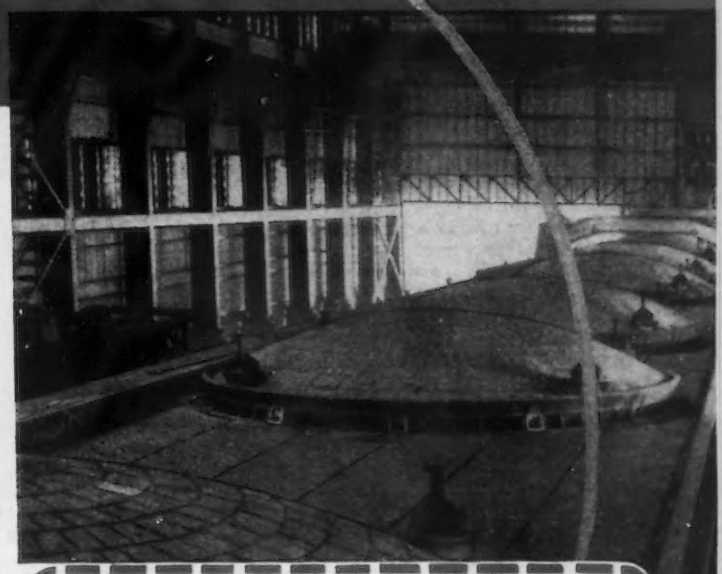
There are two principal procedures whereby, theoretically, the desired result could be accomplished. First, the sub-contractor can be authorized to sell (or buy for his own account) the excess material upon such terms and at such prices as are approved by the contracting officer, and the amount realized by such disposition can then be used as a credit against the termination claim before final settlement is effected. Second, the material can be shipped to a government warehouse where it can be checked, inspected, and thereafter remain in the possession and control of the government. Both of these procedures have apparently involved practical difficulties of administration which tend to delay final settlement for an unconscionable period of time.

As nearly as can be determined no uniform and controlling policies have yet been formulated with respect to surplus items having little or no "market" value. It is believed that contracting officers feel impelled to approach the problem too much from the standpoint of 100 per cent efficiency. The attempt to force the producing contractor constantly to adjust his own requirements in order to absorb material reported from week to week as surplus involves practical difficulties impossible to overcome in spite of the fact that this "economy" appeals to the theorist. In the case of jigs and fixtures, there appears to be a reluctance to authorize a courageous scrapping program because of the great apparent loss in dollars involved and the fear of

ONLY SALEM BUILDS ROTARY HEAT TREATING FURNACES AND CIRCULAR SOAKING PITS . . .

THE WORLD'S LARGEST, IN BOTH CASES, ARE SALEM-MADE





● The inside surface of the outside wall on the world's largest rotary furnace shows the firing and exhaust ports as well as piers of the rotating hearth (effective area of 2100 sq. ft.) on which billets rest.

The temperature for each of the five zones in the furnace is automatically recorded on a dial chart which in conjunction with a loading record chart enables the operator to determine the temperature and locate the position of any billet at any time during the heating period. The hearth is equipped with a variable speed mechanism which gives a range of 2 to 8 hours per revolution.

● These two installations were designed for heavy tonnage—the rotary for heating billets and the soaking pits for heating ingots. Both have these points in common—burn the same type of fuel (gas with oil standby), operate in same temperature range, have finger-tip controls, and a multiplicity of burners. Both installations have been in places long enough to prove our original operating economy claims. In each instance, the customer is enthusiastic about the results.

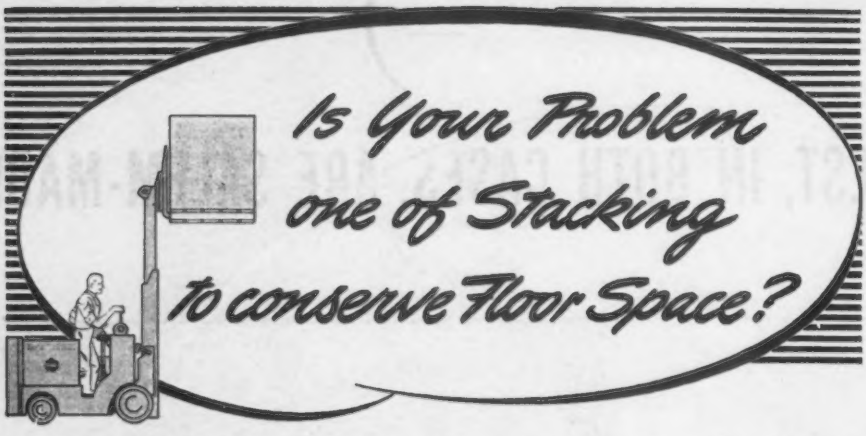
Perhaps you should consider a Salem rotary furnace or a Salem circular soaking pit for your next installation. Our engineers can supply the data.

Write SALEM for Complete Data

● The circular design in a soaking pit provides these sixteen advantages: (1) faster heating rate; (2) remarkable heat uniformity; (3) better rolling; (4) better steel; (5) less scale; (6) less chipping; (7) 1% higher yield; (8) a very minimum of cinder; (9) less fuel consumption; (10) no flame impingement on ingots or the furnace wall; (11) no washing of ingots; (12) less maintenance; (13) lower fuel expense; (14) foolproof cover for greater safety; (15) higher production in a given area; (16) lower over-all production costs.

SALEM ENGINEERING COMPANY

SALEM ENGINEERING CO. · SALEM, OHIO



Hundreds of plants and warehouses have solved this and other material handling problems with Baker Trucks. So that you may profit from their experiences, a large part of our new catalog has been given over to actual installation stories. A few cases in point are listed below:

★ ★ ★

A leading industrial engineer was given the job of designing a large model warehouse for the world's largest paint manufacturer. Baker Trucks and Tractors were specified to bring about top efficiency in the sorting, storing and shipping of the more than 10,000 items handled in this warehouse. Illustration shows one of their fork trucks stacking pallet loads of drums three-high.

One of the problems confronting the planners of this warehouse was to find a way of getting at "buried" loads with a minimum of time and effort. This was solved by steel racks—permitting the fork truck to remove the lower pallet without disturbing cartons above.

A large west-coast processing plant saves thousands of dollars annually through the use of telescoping lift trucks. The Baker Fork Truck illustrated is tiering heavy pallet loads three- and four-high to conserve warehouse space.

In paper mills, print and publishing shops, Baker Trucks have more than doubled the value of warehouse space by permitting stacking to the ceiling. Reductions up to 80% in handling costs are reported. One publisher paid for his truck in 18 months' rental savings alone.

A Baker Material Handling Engineer was called in to make a survey of a large food warehouse. Upon his recommendations, a fork truck plus a conveyor system was installed. Operating costs were reduced from 6.68c to 4.98c per ton, a saving of 25.4%. Gross savings amounted to $153 per week or $7956 per year.

The problem of stacking steel sheets has been successfully met in steel mills and metal working plants through the use of heavy duty fork trucks, handling sheets on pallets—or equipped with rams for handling heavy rolls. A special roll-over attachment tiers rolls either vertically or horizontally.

WRITE FOR YOUR COPY

Plant and production managers, traffic managers, superintendents, purchasing agents and any others concerned with material handling will find the new Baker Catalog No. 52 a valuable reference.

destroying an article of some potential future value.

The second solution, that of creating government controlled warehouses, has not as yet been tried to any great extent, but in any event the warehousing method should be resorted to only as a last resort in special cases and after every possible attempt has been made to dispose of material by scrapping. The cost of shipping and storing may involve far greater cost to the government than could be justified.

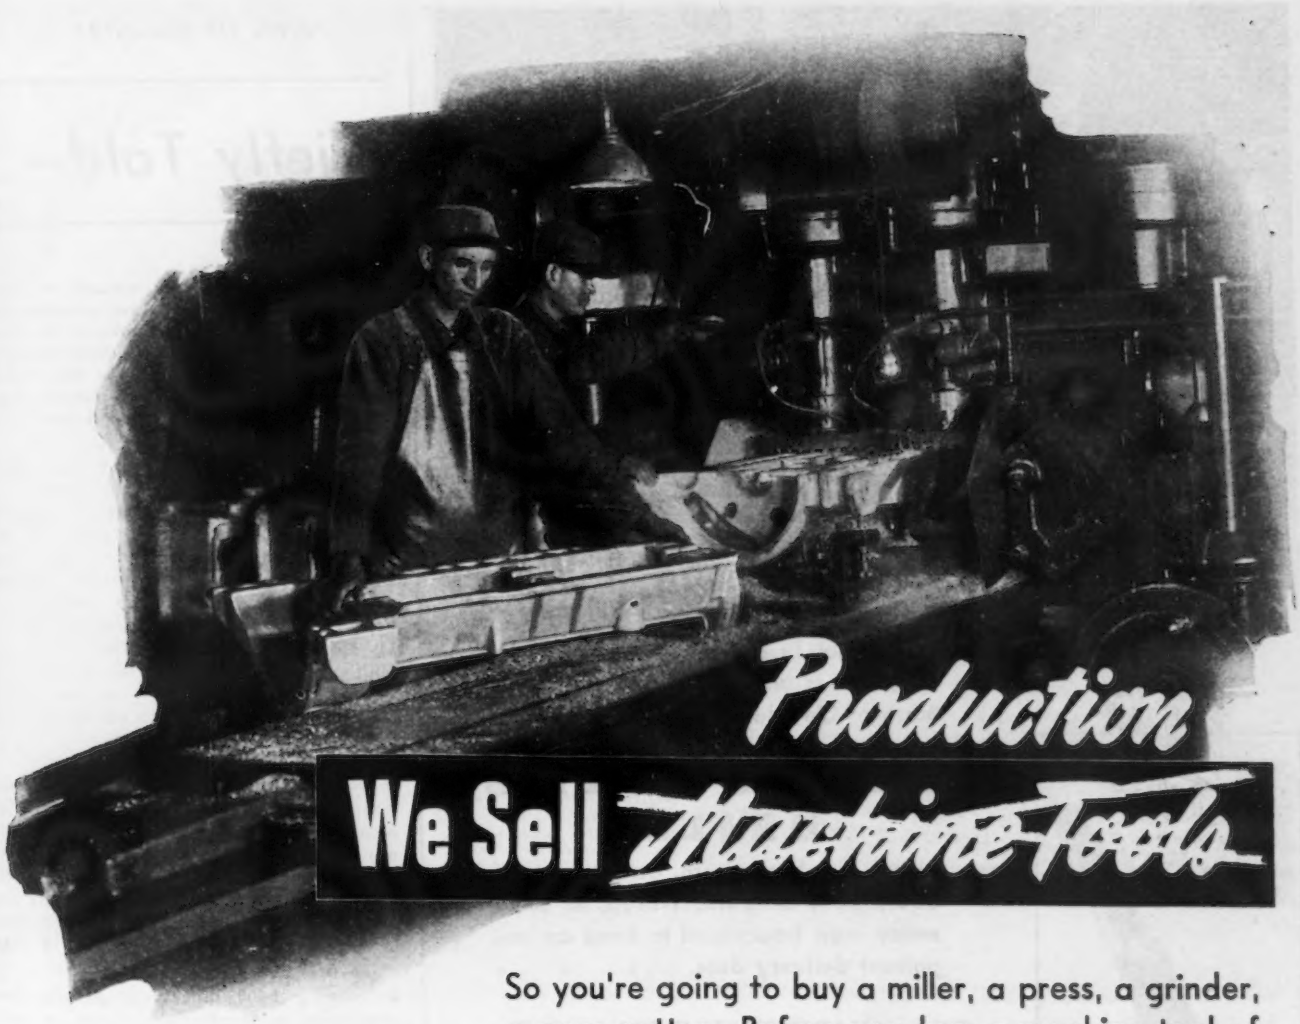
In order to get things moving, the following suggestions are offered as a starting point: 1—Let the agencies responsible for disposition of surplus materials differentiate more clearly between that which must be done to dispose of material of the type referred to, particularly jigs, fixtures, and work in process, and that which should be done to dispose of the durable goods and production facilities owned by the government. A ruthless approach should be made to the former to the extent that termination settlements are delayed by the desire to obtain a disposition price bearing a close relation to cost.

2—All other sources of informed opinion should by concerted effort educate the public to the view that semi-processed and "excess" material should be considered expendable, largely to the same extent as an exploded shell or bomb, and that its cost must be absorbed and written off as a necessary cost of waging total war. It seems unrealistic to assume that government contracting officers will, in fact, carry out the salvage program in a courageous and effective manner if the results accomplished by them are to be tested and criticized in the light of normal industrial, business, or even governmental procurement practices.

3—The passage of legislation of the type recommended in the Baruch-Hancock report should be pushed with all possible speed so that the procurement agencies will have a statement of Congressional policy to back up their efforts. Senate Bills 1718 and 1730, particularly the latter and if certain clarifying amendments are made, deal with this and seem to cover the ground in all essential respects.

Cooper with WPB

• • • **Stanley M. Cooper** has been appointed an assistant director of the Tools Division, WPB announced. Mr. Cooper has joined WPB to handle problems relating to anti-friction bearings.



We Sell *Production* Machine Tools

So you're going to buy a miller, a press, a grinder, a gear cutter. Before you buy a machine tool of any kind—find out if there's a used tool that would serve your purpose.

For the answer to these and many other machine tool requirements—see an MDNA dealer first before you buy. He will make every effort to find you the right machine for the right job at the right price. Invite an MDNA dealer into your shop—so that he may become familiar with your production problems—and catalogue your needs when he is shopping around for available used machine tools. Your MDNA dealer is interested in you as a permanent customer. Hence he doesn't sell just machine tools. He tries to service your production problems. So before you buy any machine tools—new, used or rebuilt—see what an MDNA dealer has to offer.

LOOK FOR THIS SEAL OF INTEGRITY

MDNA

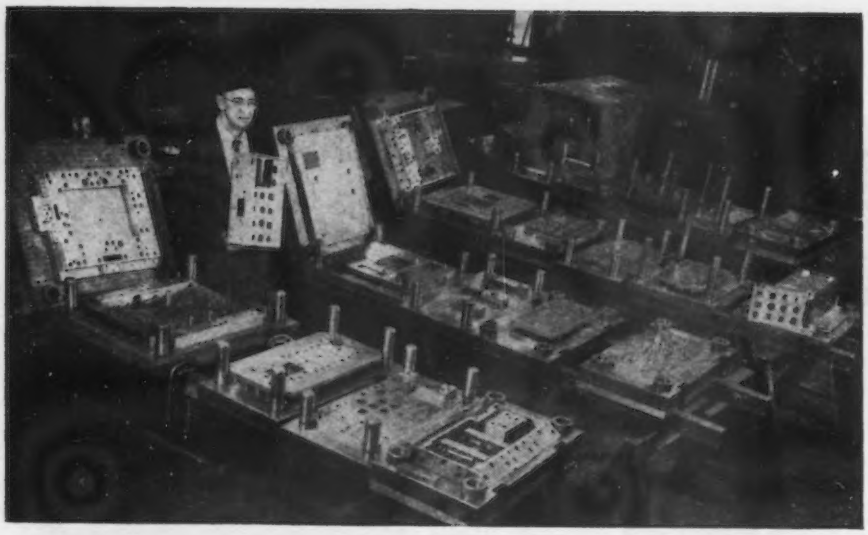
MEMBER

WHEN BUYING USED OR REBUILT MACHINERY

When you see the MDNA seal in the advertising of a used machine tool dealer you have reason to feel unusual confidence in the values which he offers . . . because his display of that seal is public notice that he has subscribed, both in spirit and in letter, to the code of ethics adopted by the National Machinery Dealers Association, an organization of dealers in used and rebuilt machinery.

MACHINERY DEALERS NATIONAL ASSOCIATION

20 NORTH WACKER DRIVE CHICAGO (6) ILLINOIS



From Parts Prints to Press in 8 Weeks

—No small task in these days of priorities, delays and last minute changes. Barth of Cleveland gives high credit to

"HARDSTEEL" DRILLS

which enabled them, on the signal equipment dies illustrated, to save many man hours and to keep an important delivery date. « « «

With a "HARDSTEEL" Drill in an ordinary drill press and following simple instructions regarding speed and pressure, any mechanic can easily drill clean holes through steel hardened by any process—40 Rockwell "C" or harder.

A time saver when last minute emergency changes come through on hardened dies and parts. And the only way to assure matching of hardened parts at assembly—drill after hardening.

Used throughout industry for parts recovery and for production work—made in all sizes ⅛" to 1".

Briefly Told—

• 12,000 tons of copper, enough for more than 1,200,000,000 machine gun cartridges and the equivalent of 1,100,000 miles of telephone wire, was returned to the national stockpile from the telephone plant of the Bell System during 1943, says the Western Electric Company, supply organization of the System.

•

• "Guarantee certificates of re-employment" are being mailed to every employee of Stokes Industries, Covington, Ky., lathe manufacturers, now in the armed forces. According to officials of the company, these certificates declare that the man in military service "is hereby guaranteed, upon presentation of his Honorable Discharge papers from the United States Armed Forces, that he will be re-employed by Stokes Industries at the prevailing wage scale at the time of his re-employment."

•

• Leo A. Sweeney, USES district superintendent, Buffalo, estimates 21,000 workers will be needed in Buffalo war plants in the next six months and that only about 8000 can be expected from all sources, leaving a potential shortage of 12,000. Sweeney says there are more people employed in non-essential lines in the district today than there were in 1940.

•

• Covering 5000 office and professional employees in its Buffalo plants, a contract has been signed by Curtiss-Wright Corp. and the United Office & Professional Workers, CIO. . A pay increase schedule, jointly agreed upon, will be submitted to the WLB for approval. Other provisions relate to vacations, grievance and arbitration machinery, seniority rights, and joint job-evaluation.

•

• About 50,000 employees of Youngstown and Mahoning County were placed under a mandatory 48-hr. week on March 1 by order of the WMC. April 1 has been set as the deadline when all plants employing more than eight workmen must comply with the order. About 2800 plants are affected.

•

• For January, Canada's external trade, excluding gold, was valued at $372,359,000, a gain of $66,000,000 over the corresponding month of 1943. During the month Canadian imports were valued at $126,369,000, down from $127,299,000 a year ago. Exports, excluding gold, in the same month were up 36 per cent over the corresponding month a year ago to $242,011,000.

•

• The James H. Hunter Machine Co., North Adams, Mass., filed an application with the National WLB for permission to grant a wage increase of 10 per cent and one week each year vacations with pay to employees who have been with the firm a year or more. The company filed a similar application with the board Nov. 24, 1943, but was turned down.

•

• The AFL Molders Union and Springfield Bronze & Aluminum Co. have signed

motor vibration absorbed

In Logan Lathes the smooth operation essential to finely finished precision work is doubly assured... first, by rubber cushioning at vital points... second, by carrying the countershaft on a three-point suspension. To absorb the motor's vibration, to prevent its transfer to the lathe proper, the patented Logan countershaft is rubber cushioned at all three of its main supporting points... the pedestal red and the two hinge pins. In addition, the cone pulley guard, which covers both countershaft and headstock, rests on rubber buttons. *The entire Logan countershaft assembly is so designed that at no point is there a direct metal-to-metal contact between countershaft and headstock.* Furthermore, the three-point suspension steadies the whole countershaft assembly so that it cannot rock. This combination of rubber cushioning and three-point suspension is another example of the advanced design that assures sustained accuracy, safe operation, long life, and high-speed, low-cost production in all models of Logan Lathes. Write today for your copy of the latest Logan Catalog.

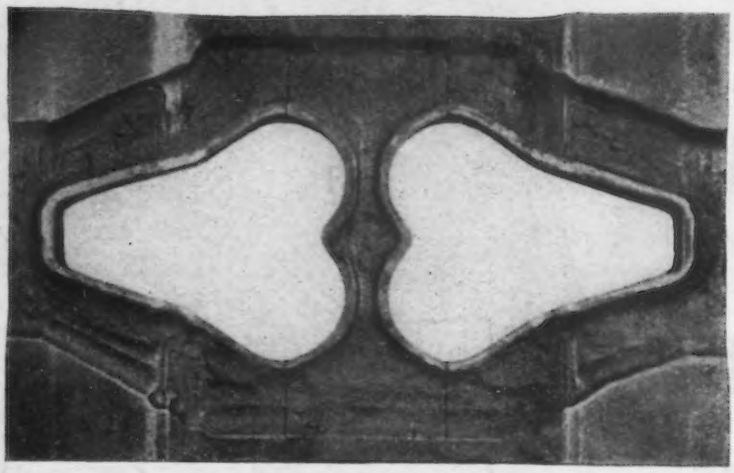
THIS DIE WILL LIVE!



Hard-Facing with Wear-Resistant Coast Metals Enables it to "Consistently Trim 100,000 Forgings..." Time after Time

There, in a word, you have the story of this trimming die for forming tank tread end connectors.

Made of ordinary carbon steel, 3" thick, it is constructed with a 3/16" x 3/16" ledge, cut into the top edge of the trimmer. This cut-out is protected with a wear-resistant Coast Metals Hard-Facing, and then the overlay is ground to the correct size and shape. When the die needs reworking, another Coast Metals overlay, requiring only 4 or 5 ounces of weld rod, makes it good as new, ready for another life of genuine service.

Coast Metals can be welded either by the electric arc or the acetylene torch to all ferrous metals, including manganese steel, alloy steel, cast iron and chilled iron. New booklet, "Your Best Protection Against Wear" contains full details. Write for your copy today.

COAST METALS, INC.

MAKE YOUR EQUIPMENT LAST LONGER

a contract that stipulates that any employee found "agitating trouble" in the plant will be discharged. All grievances will go through regular channels so they may be dealt with fairly and speedily. In other words, the union agrees to support management when an agitator is discharged, and management agrees to back the union when it reports an agitator for discharge. The contract calls for a wage increase of 10c. per hr., contingent upon Regional WLB approval.

●

• Washington draft controversies have stirred up a hornet's nest of organized charges of indiscriminate drafting by local boards, and as a result industrial plant interest in the fate of manning or replacement tables is decidedly alive. Records show that draft boards generally have stuck to manpower ratings as listed on industrial replacement tables. There have been a few exceptions in special cases when draft boards have questioned the priority rating of a worker. In such cases, however, rulings by draft boards have been appealed and rejected almost 100 per cent.

●

• Approximately half of the firms coming under the 48-hour work week ordered by WMC, which went into effect in Boston March 6, have applied for at least partial exemption from the ruling. Some 4000 industries are listed as essential and are affected by the order. Of that number, 1225 requests for exemption have been tabulated, and the WMC office staff still has many more to list. A large majority of requests for exemption are for special groups of workers whose jobs do not bring them under the ruling.

●

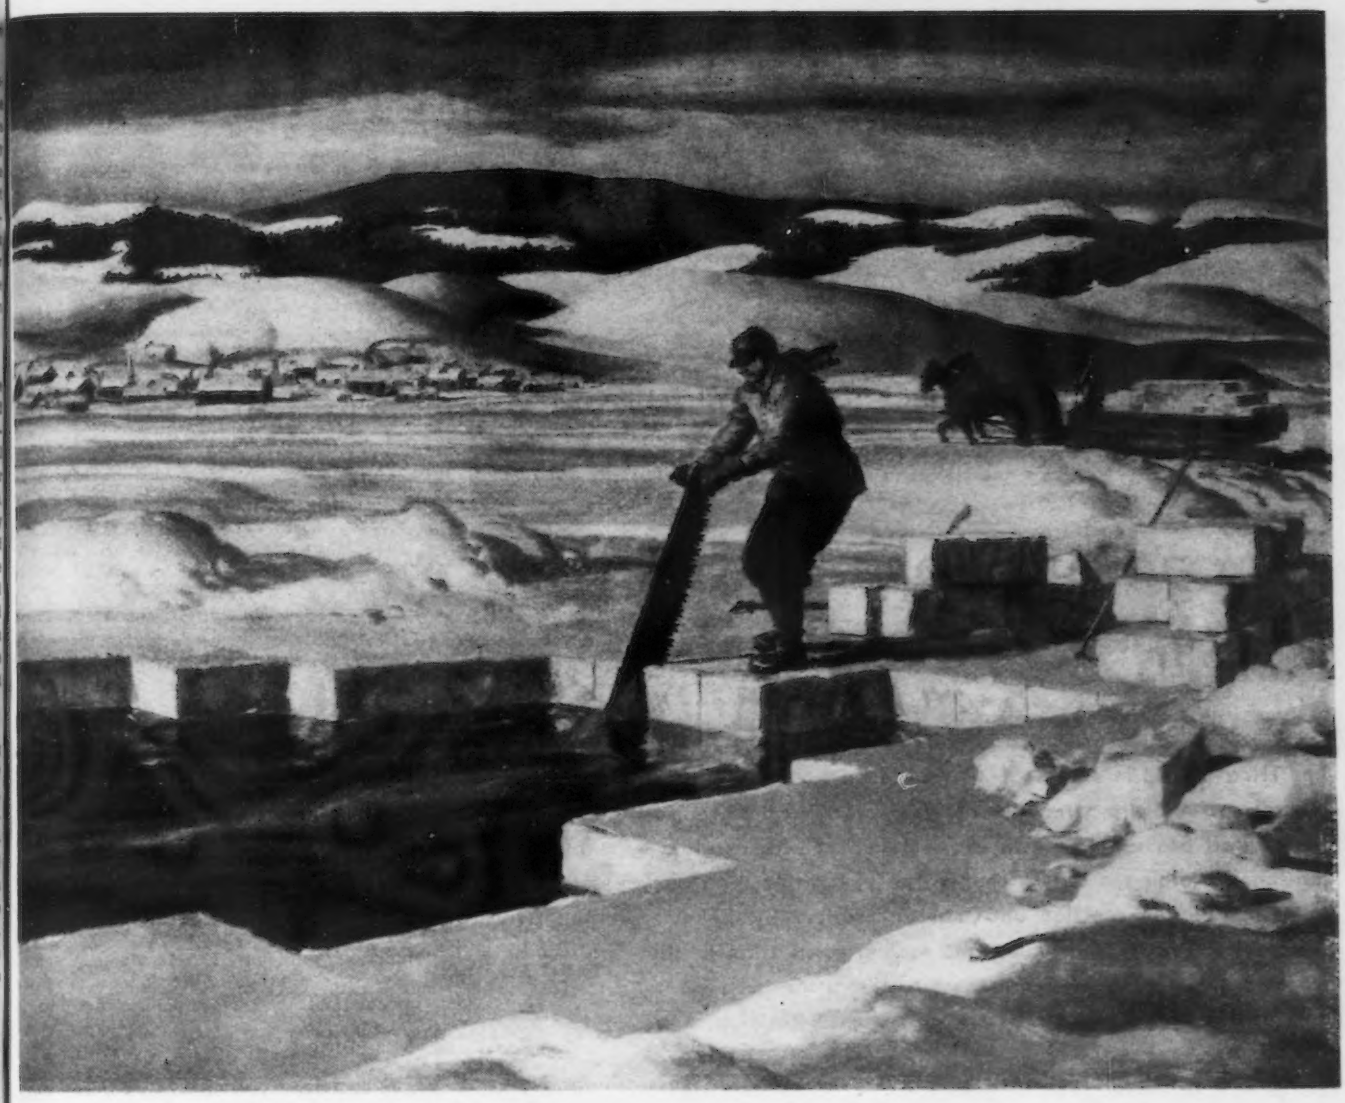
• Consolidated net profit of $4,341,200 for 1943 after all expenses and taxes is reported by the M. A. Hanna Co., coal, ore, dock and vessel operators. The profit compares with $4,254,663 in 1942. Total tonnage of all kinds handled in 1943 was 27,500,000 tons compared with something over 25,000,000 tons in 1942. The company handled 7,545,000 gross tons of iron ore in 1943, comparing with the all-time record of 8,570,000 gross tons in 1942.

●

• Auditors of the Air Forces Materiel Command are checking inventory records in the Buffalo plants of Curtiss-Wright Corp., as the result of a mixup in bookkeeping. The company is building several types of airplanes under both cost-plus-fixed-fee and flat-price contracts. It has been discovered certain materials may have been charged to cost-plus contracts when they should have been charged to flat-price contracts and vice versa. This situation is attributed to failure of bookkeeping methods to keep up with production expansion. There is no question of shortages in parts inventories, but only a clouded picture of where and how the parts have been entered on the books according to best authority.

●

• The last of 1200 triple-deck troop sleepers built for the DPC rolled off the Pullman-Standard Car Mfg. Co., assembly line on March 6, just four months after production began. In turning out these three-tier sleeping cars Pullman-Standard maintained an average production rate of 12 a day, which it set when it tackled the order. The plant is now busy on another



Ice Cubes of Yesterday

TURN back the clock to yesterday. Across the years comes the ring of biting saws. The crickety squeak of sled-runners and bundled feet, on crispy snow. The laughter and banter of toiling men. The blowing of frosted breath. Grunting! Clanking! — *It's ice-cutting time!*

In those days, it wasn't easy to keep next summer's food from spoiling.

HOW TIMES HAVE CHANGED!

Look at that gleaming white refrigerator of yours. Contemplate its contributions. More than just a 24-hour-a-day servant; more than just a stimulus to the family appetite; more than just a beautiful piece of furniture—it is literally a guardian of human lives — *your family protector!*

Other inventions have been more spectacular, more talked-about; but none has added so much to the happiness and comfort of so many people.

A grateful nation pauses to give thanks to American inventive, engineering and manufacturing genius for the blessings and conveniences of *the mechanical refrigerator!*

HOUDAILLE* is proud to have contributed to the dependability and excellence of modern refrigeration—proud to have worked hand-in-hand with the producers of mechanical refrigeration and other kindred household appliance industries.

We will continue, increasingly, in the postwar period, to cooperate and counsel with these important industries, in their efforts to put still further comforts and conveniences into your home.

CORSAIR HAS EVERYTHING
Speed · Power · Guns

WITH a Speed in excess of 400 miles an hour, this fast-climbing, heavily armed and armoured Corsair F4U is one of the great combat planes of the United States Navy. In every detail the Corsair is a superb fighting machine. Nothing is left to chance; no part of its construction is too small to escape rigid inspection and thorough testing by the builders and pilots. This calls for expert machining and tooling so that the finished job will be a masterpiece of precision workmanship. From the Fenn Plants, a steady flow of precision built parts and assemblies go to the manufacturers of the famous Corsair.

FENN FOR SPECIAL MACHINERY

Fenn Plants have built their reputation over the years by building special machinery and handling difficult engineering jobs. They have the plants, facilities and experience for designing and building special machinery and they welcome inquiries regarding work of this special character.

ARE YOUR FUTURE PLANS IN THE BLUEPRINT STAGE?

When the time comes for reconversion to peace time production, Fenn engineers, toolmakers and machinists will be ready to serve you. It is not too early to think of planning now.

AMBULANCE JEEP: *How easily a Jeep can be converted into an ambulance is illustrated here. The little arrangement leaves room for the driver and attendant.*

Your *future* **Diesel installation** can operate by air *through* **W·A·B** *controls*

One war development that can pay you big post-war dividends is in the field of engine controls, where W·A·B equipment is doing a remarkable job.

With W·A·B Controls, you can govern all functions of one or more Diesel engines from a central point. Speeds can be precisely established, and varied in small increments. Simple and positive interlocks make it impossible to damage equipment by accidental changes in sequence of control operations. Synchronization or load balancing of engines in parallel is simple and easy. And control may be readily extended to related functions of the driven machines.

When you are thinking about improving your production methods—or improving any product where an operator is involved—it will pay you to consider the contribution that W·A·B Controls can make, and to give them a place in your planning.

compared to $712,730 in 1943. Building contracts awarded in Cook County numbered 578 valued at $3,971,000 compared to 304 valued at $2,177,000 a year ago. Factory payrolls rose 29.5 per cent and the number of workers 8 per cent. Electric power consumption was up 8.7 per cent.

•

• Warning that the steel cylinder supply situation is becoming critical was contained in an appeal by the National Ammonia Division of E. I. du Pont de Nemours & Co. to industrial consumers to empty and return the cylinders in which they receive ammonia promptly. Cylinder manufacturers right now are hard pressed making torpedo housings, bombs, shells and other war materials. The supply of cylinders is adequate to handle all requirements if they are kept moving between consumer and producer. It is unnecessary for users to maintain large inventories of ammonia stored in the shipping containers.

Surplus Property Policy Board Meetings

Washington

• • • **Surplus Property** Administrator W. L. Clayton held the first meeting of the Surplus War Property policy board on March 2 at which time organization plans were discussed.

The following agency heads were invited to membership with the option of choosing representatives of their agencies:

Maj. Gen. Philip Fleming, administrator of Federal Works Agency; Leo T. Crowley, administrator, Foreign Economics Administration; Maury Maverick, chairman, Smaller War Plants Corp.; Sam Husband, director, Reconstruction Finance Corp.; Admiral Emory S. Land, War Shipping Administrator; Donald M. Nelson, chairman, WPB; Harold D. Smith, director, Bureau of the Budget; Marvin Jones, War Food Administrator; Charles P. Taft, chief, Wartime Economic Affairs, State Department; John Sullivan, assistant secretary, Treasury; Maj. Gen. Lucius Clay, director of material, War Department, Army Service Forces; Capt. Lewis L. Strauss, assistant chief of procurement and material for industrial readjustment, Navy Department; Francis Biddle, Attorney General; and L. W. Pogue, chairman of the Civil Aeronautics Board.

Marketers Plan Fact Forum

Newark, N. J.

• • • **The Industrial Marketers** of New Jersey have planned a Fact Forum for the Future, with an all day meeting on March 21, at the Essex House in Newark.

Pre-forged steel for greater uniformity

A prominent manufacturer of gears and axles prefers and specifies Follansbee's PRE-Forged steels for such jobs as this ring gear. The reason for Follansbee's selection is the ability to deliver the same high quality steel required—*shipment after shipment.*

This uniformity of quality is achieved through Follansbee's unique PRE-Forging process—the forging of ingots into blooms or billets. Small basic open hearth furnaces and the skill of a compact organization are also important factors which combine in producing high quality alloy steels to specifications.

For the tough jobs of today and tomorrow, you can profit by the uniformity of Follansbee's high quality PRE-Forged steels.

Productioneered

BY KOLD-HOLD

Typical of Kold-Hold "Productioneering for Industry" is this experience of a large automotive and aviation manufacturer (name on request).

Faced with a tough, costly bottleneck, Kold-Hold "productioneered" a cold processing unit to fit the manufacturer's problem . . . the results were — production per hour doubled, serious bottleneck broken, closer fits attained and distortion eliminated. This is an outstanding Kold-Hold "productioneering" performance.

Maybe you have a similar "toughie." A look through our catalog, S-Z 431, may show you a machine that will fit your cold temperature application. Tell us about it and we'll help you "productioneer" your production problem. Kold-Hold machines over a range of from —100° to +200° on capacities from 2 to 400 cubic feet. If pressure and humidity control are required, we have them, too.

Seized Patents Deal With Non-Ferrous Metals

• • • This is the eighteenth list of seized enemy patents available on license from the Alien Property Custodian. These patents are grouped in classes. In the following lists, subclass numbers are shown first in parentheses, followed by the patent number, description of the patent, the inventor's name and nationality, and the date the patent was issued.

This series began in the Nov. 4 issue of THE IRON AGE, page 95, at which time rules and procedures for obtaining the patents were described along with full information about their usage and possibilities. Seized patent applications were listed in THE IRON AGE on July 8.

Class 75—Metallurgy

(133) 2,241,742. Process of producing alkaline-earth molybdates in lumps. G. Schuphaus, Germany. 5-13-41.

(134) 2,270,594. Soldering alloy. J. Leuser, Germany. 1-20-42.

(135) 2,143,217. Process for reducing the grain in precious metals and their respective alloys. W. Truthe, Germany. 1-10-39.

(135) 2,149,257. Method for production of beryllium-copper alloys. H. Gruber, Germany. 3-7-39.

(135) 2,251,088. Process for the production of alloys containing beryllium. H. von Zeppelin, Germany. 7-29-41.

(135) 2,251,089. Process for the production of alloys containing beryllium. H. von Zeppelin, Germany. 7-29-41.

(136) 1,742,417. Production of metal alloy and of articles made thereof. W. Schrobsdorff, Germany. 1-7-30.

(136) 1,803,882. Metal composition partially produced by a process for condensing or consolidating a powdered metallic aggregation or coherent mass of powdered particles, or sintered metal body. R. Walter, Germany. 5-5-31.

(136) 1,811,068. Alloys characterized by great resistance to wear and adapted for use on tools for cutting. R. Walter, Germany. 6-23-31.

(136) 1,840,457. Method of making the carbides of the relatively infusible metals. H. Lohmann, Germany. 1-12-32.

(136) 1,847,617. Hard alloy. K. P. zu Lowenstein and W. Muller, Germany. 3-1-32.

(136) 1,864,567. Alloy of azotized character. R. Walter Germany. 6-28-32.

(136) 1,992,372. Hard metal alloy. J. Holzberger, Germany. 2-26-35.

(136) 2,018,752. Alloy of tungsten carbide with some other metal of lower melting temperature or with a plurality of metals of the iron and chromium groups respectively. R. Walter, Germany. 10-29-35.

(136) 2,036,245. Metals and alloys of the iron and chromium group in association with previously unknown nitrogen compounds. R. Walter, Germany. 4-7-36.

(136) 2,056,604. Process for increasing the resistance against corrosion of aluminum and aluminum alloys. W. Guertler, Germany. 10-6-36.

(136) 2,059,041. Hard metallic alloys for implements and tools. K. Schroter and K. Moers, Germany. 10-27-36.

(136) 2,077,239. Hard metal alloys produced by melting or sintering and adapted for the manufacture of tools and working implements. J. Hinnuber, Germany. 4-13-37.

(136) 2,116,400. Hard substance alloy. P. Marth, Germany. 5-3-38.

(136) 2,121,448. Hard metal compositions comprising in preponderating amount one or more highly refractory carbides and which are manufactured by pressing and sintering a pulverized mixture. G. Ritzau, Germany. 6-21-38.

(136) 2,123,046. Sintered hard metal alloys. J. Hinnuber, Germany. 7-5-38.

(136) 2,128,146. Sintered hard metal alloys. J. Hinnuber, Germany. 8-23-38.

REGULAR INDUSTRIAL GLOVES

They wear longer—taking the roughest handling and giving as much as *7 times the service* of ordinary work-gloves. A special knit in the Jomac Fabric makes this extraordinary wear possible. This hidden lock-stitch keeps the thick pile in place . . . and gives thousands of sturdy "cushions" which provide a semi-heat-resisting glove that protects the hands . . . allows a breathing-space to make possible the handling of reasonably hot metals. Endorsed by leading American shops and foundries.

And Jomac Gloves can be laundered, too. They are easy to wash, easy to keep clean . . . a safeguard against the dangers of dermatitis and other skin infections.

(Jomac also makes the famous Heat-Resisting Gloves.)

TEST THEM!

Just try JOMAC GLOVES on your stiffest jobs. Test them for wear, for washability, for economy, for *increased production*. Write for *full* details.

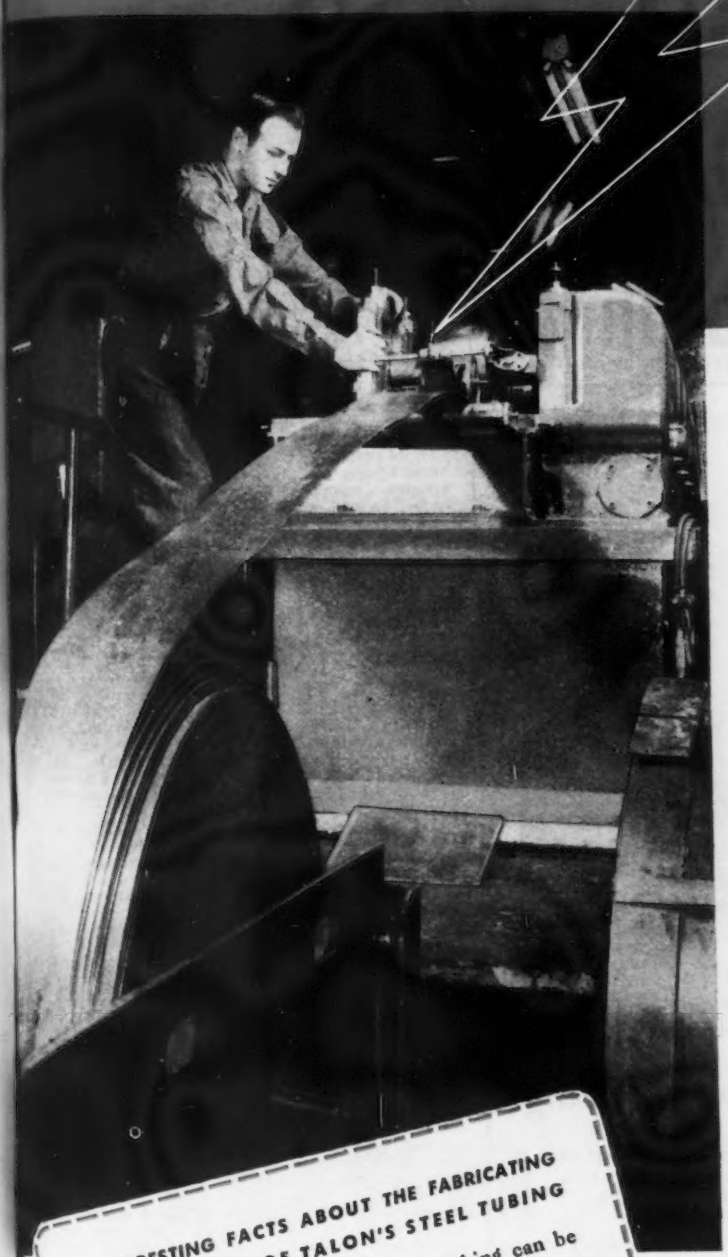
Photograph—Operator checks position of strip as it enters forming rolls. In a matter of seconds, it will emerge at the other end as a welded piece of uniform Talon's Tubing.



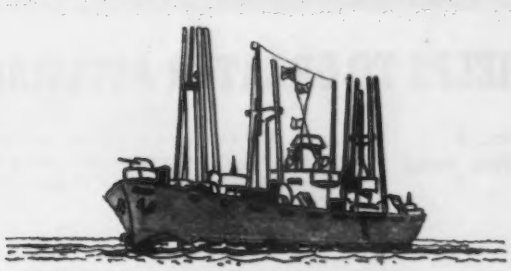
Uniformity of TALON'S Electric Welded Tubing Assured By Careful Selection of Strip Steel

● In the manufacture of Talon's Electric Welded Steel Tubing, coiled, flat stock feeds continuously through forming rolls which shape the strip into a round. Then the butted edges pass under the electric resistance welding unit to form a continuous tube wall.

Careful selection of strip assures correct wall thickness, concentricity, and accurate size in the finished tubing. Talon checks each coil for accuracy of gauge and width and condition of surface. The analysis, hardness, and microstructure of the steel are also checked at regular intervals. That is why Talon's Tubing will meet the requirements of your particular application. Your inquiries will receive immediate and careful attention.

INTERESTING FACTS ABOUT THE FABRICATING ADVANTAGES OF TALON'S STEEL TUBING

Change of Section . . . Talon's Tubing can be beaded, expanded, swaged, spun, flanged, upset, grooved, rolled, fluted, flattened, tapered, and otherwise changed in cross-section to meet an endless variety of design requirements.



Talon's Tubing is equal to the tough jobs for which it is used. It is dependable in our ocean-going vessels where long tie-ups for tube replacements must be avoided as much as possible. And remember, Talon's rigid inspection assures this long tube life and less maintenance.

HELPS TO GREATER ACCURACY *in Spring Coiling*

No. 1 Wire Feed

Possession of a Torrington Spring Coiler is the first step to greater accuracy in Spring Coiling. Then comes correct operation and maintenance of your Torrington Coiler.

So that our customers may get the full benefit of the precision built into these coilers, we will publish during 1944 a series of advertisements incorporating suggestions for preventive maintenance and important operating hints. The first of these follow:

1. Movement of the crank gear adjustment block will cause inaccuracy. Always be sure to lock the feed adjustment.

2. Make certain that the start and stop clutch on the machine is not slipping, as this causes irregular operation. Slippage is easily remedied by pulling a spring loaded pin and turning up the clutch adjusting ring to tighten. Adjustment is made from outside the clutch without the use of any tools.

3. A gummy free wheeling clutch, excessive wear in this clutch, or wear in the segment or crank gear, are prime causes of inaccuracy.

April 20th—More about *Wire Feed*

FAMED FOR THRIFT

FORD TRIBLOCS have an amazingly long life. Given proper care—they are up on your ceiling for the duration of your plant. They are famed for thrift.

FORD TRIBLOCS are ideal for constant hard usage. Spur gear construction, ball-bearing equipped, and many other features that assure enduring efficiency, safety and low maintenance cost. Capacities: ¼ to 40 tons.

FORD SCREW HOISTS are built primarily for jobs on which smooth operation and accurate spotting of loads are required. Light weight; highly portable. Capacities ½ to 5 tons.

FORD DIFFERENTIAL HOISTS are constructed for intermittent service where speed, portability and price count. Capacities ¼ to 2 tons.

The "Silent" Weapon *that's making a* Big NOISE

Official U. S. Navy Photograph

INVISIBLY, under a mantle of night, twin shafts of steel advance swiftly through the water to within torpedo range of the enemy supply ship. Beneath, in the sub, a crew of young Americans waits tensely for a command. Then: "Up periscope." Now their prey is framed in the cross-hairs. "Fire one!" Their tin fish doesn't miss.

AS operations have extended over new continents and new oceans in this vast, global conflict, the submarine has taken on greater and greater importance as a primary *offensive* weapon for the United Nations.

So today at The Electric Boat Company, one of the nation's foremost sub builders, an army of men and women is working to give America the world's greatest underseas fleet. And here, again, you find modern DeVilbiss Spray Painting Equipment doing its part. Officials of Electric Boat state that *"one man using DeVilbiss Spray Equipment accomplishes what four did previously with hand brushes."*

Whatever your company's job in this war, there is DeVilbiss Spray Painting Equipment that will help *you* get the work out faster with less man hours of labor. After "V" Day, too—no matter how your peacetime products may differ from those you are making today—you can depend on DeVilbiss for the time-saving answer to any coating or painting problem.

How to beat SURPLUS INVENTORY!

What with cancellations, cutbacks and design changes, these are days to check every source of excess inventory. It's time to start streamlining your stocks—to get "light on your feet" for the future.

To help beat the "surplus" problem, why not buy more of your steel from warehouse? By buying only what you need for immediate production, you avoid leftovers and dead stock when contracts change. Frasse stocks of cold finished bars, tubing, stainless steel, alloy and aircraft steels and tubing are now in good shape. By ordering from Frasse as you go, there's no surplus to fear when contracts are cancelled or cut back.

Your future operations can be seriously hampered by heavy, awkward surpluses. Why pile up more? Start streamlining today by using Frasse inventories instead.

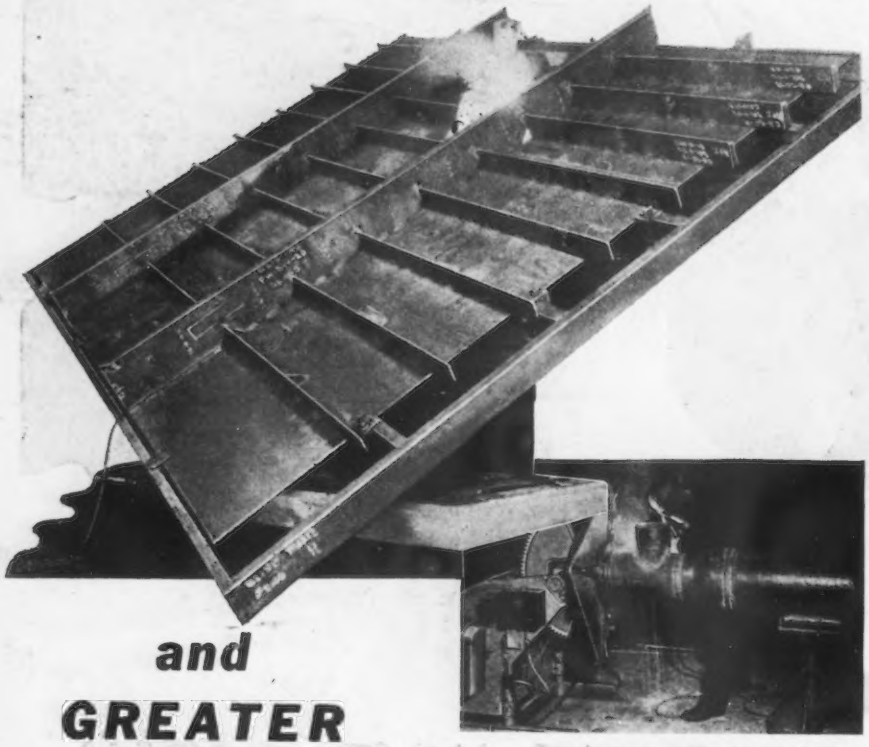
EFFICIENT POSITIONING
...means BETTER WELDING



and GREATER OUTPUT

Method used in a shipyard for welding high pressure pipe.

When weldments reach these proportions, Welding Positioners become a necessity, especially when stronger welds and speedy production are essential. Welding large structures on the floor wastes time and reduces welding speed. Crane time, critical in most shops, is lost through much unnecessary handling.

The large photograph shows how a battery of Ransome 16,000 lb. capacity positioners is used in the shops of the Harris Structural Steel Company in New Market, New Jersey. The work shown is a pre-fabricated ship section. Notice the holding cradle which is bolted to the positioner table top. The weldment is quickly clamped to the cradle for all down-hand position welding.

Our engineers will be glad to help with your positioning welding problems. Industrial Division, Ransome Machinery Company, Dunellen, New Jersey.

Wickman

SWISS TYPE AUTOMATICS

and their various attachments

In addition to normal turning and forming operations

The No. 2 Wickman machine illustrated is equipped with both three-spindle and slotting attachments. Three other attachments for drilling, threading and taper turning are also supplied for this machine. All Wickman attachments are easily interchangeable.

Do you manufacture parts which are in any way similar to those illustrated above—which require any of the operations listed? Are you interested in holding production runs of those parts to tolerances of ± .0005″ or closer and securing finishes as fine as 25 micro-inches? If your answers to these two questions are in the affirmative, Wickman Swiss Type Automatics have a place in your production.

Two Swiss Type Automatics are produced by Wickman. The No. 2 machine shown above has a ½″ bar capacity and will handle pieces up to 4″ long. The No. 1 machine has 5/32″ bar capacity, maximum length capacity of 1 9/16″.

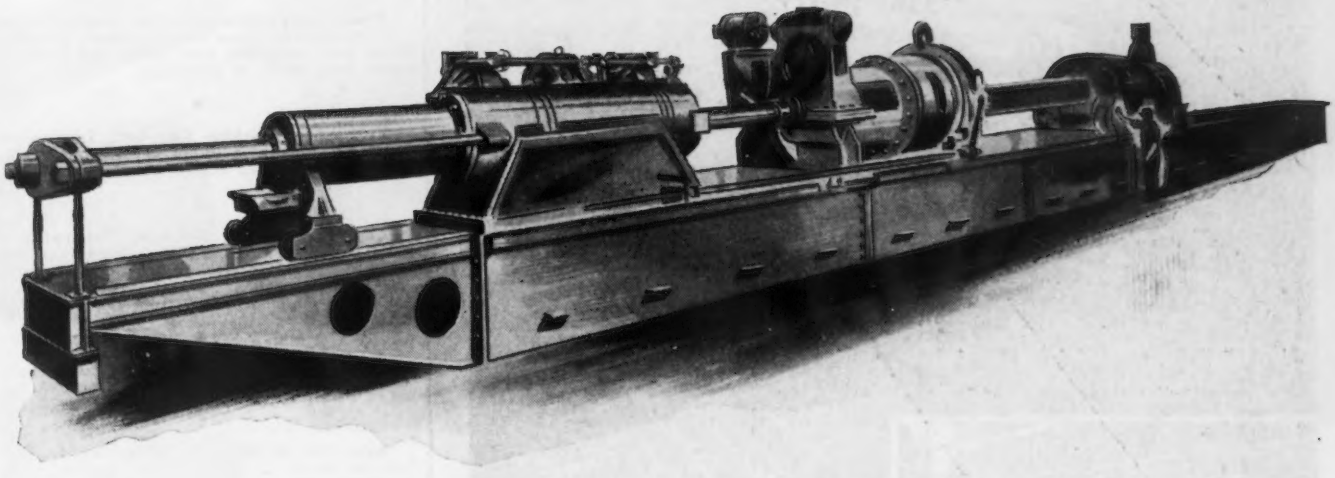
New WPB Steel Division Appointments Made

• • • **H. J. French has** been named assistant director for raw materials and facilities of the WPB Steel Division, it was announced on March 7. Mr. French succeeds Carl W. Meyers, who has resigned to return to his former position with the Republic Steel Corp. at Massillon, Ohio. Mr. French has been serving as chief of the WPB Metallurgical and Conservation Branch.

S. A. Crabtree, Chicago, has been appointed successor to L. E. Creighton as chief of the WPB Alloys Steel Branch. Mr. Creighton, who recently resigned, has returned to his former position with the Rotary Electric Co., Detroit. Mr. Crabtree will also continue as deputy assistant director for production.

WE'D LIKE TO WRING TOJO'S NECK ... THIS WAY



A typical application for HELE-SHAW FLUID POWER

YES, if we had our choice of means for wreaking vengeance on Tojo, this "Twister Stretcher" would get the call. It's a right handy "little" gadget (109 feet long) used in certain essential plants for taking the kinks out of structural aluminum shapes and bars.

The operator slips in an I-beam, channel, or angle and with push-button ease exerts up to a 350-ton pull on the shape, twisting it at the same time to remove any distortion.

The stretching pressure is supplied by Hele-Shaw Fluid Power generated by a Hele-Shaw Pump. Smooth stretching action and ease of control characterize the operation. Hele-Shaw Fluid Power might be equally effective for a current or future application you have in the back of your mind... for stretching, squeezing, pushing, pulling, lifting, tilting, and a long list of similar operations. Want to find out?

OLIVER IRON AND STEEL Corporation

SOUTH TENTH AND MURIEL STREETS · PITTSBURGH 3, PA.

Trade Notes

Harnischfeger Corp., Milwaukee, has established a separate repair sales division to facilitate service to customers on all P&H products, including electric overhead traveling cranes, hoists, a.c. and d.c. welders, welding electrodes, and welding positioners.

•

Pemco Corp., Baltimore, has just completed the entire renovation of its research facilities. New equipment has been added and additions have been made in personnel.

•

Logansport Machine Co., Inc., Logansport, Ind., has appointed the Rudel Machinery Co., Inc., 100 East 42 Street, New York, as its representative.

•

Gould Commercial Division, National Battery Co., Depew, N. Y., is shifting manufacture of aircraft batteries to a newly acquired plant in Zanesville, Ohio. New machinery as well as equipment taken from Depew will be installed.

•

Bedaux Co., Inc., New York, has changed its name to Albert Ramond and Associates, Inc.

•

Atlas Car & Mfg. Co., Cleveland, has appointed the A. J. Philpott Co., Denver, as its representative in that vicinity for storage-battery locomotives, electric industrial trucks and industrial haulage equipment.

•

Aga Metal Tube Co., Elizabeth, N. J., has changed its name to Agaloy Tubing Co. and has taken over larger quarters at Springfield, Ohio.

•

Cross Gear and Machine Co., Detroit, has changed its name to the Cross Co. to cover the company's broadened activities which include a wide range of special machine tools. There are no changes in personnel or general policies.

•

Nelson's Screw Machine Products announce the removal of its plant and executive office to West Street, Plantsville, Conn.

•

Duff-Norton Mfg. Co., Pittsburgh, manufacturers of jacks for industrial use, has removed its eastern district offices to 250 Park Avenue, New York. George L. Mayer is in charge.

•

Reliance Aircraft & Tool Co., Ltd., Belleville, Ontario, has been taken over by Reliance Industries, Ltd.

•

National Battery Co., St. Paul, will begin production on April 1 in its 11th plant situated in Sioux City, Iowa. Production in the new plant will be devoted entirely to farm-light storage batteries.

•

Chicago Alloy Products Co. has moved its plant to larger quarters at 19th Street and Washtenaw Avenue, Chicago. J. J. Chernyk now manages the business, succeeding his father, the late Ben Chernyk, president and founder. The company purchases and processes stainless steel, high speed steel, nickel and nickel alloy steel scrap.

•

The West Bend Aluminum Co., West Bend, Wis., has purchased the business and plant of Kissel Industries, Inc., Hartford, Wis., to take possession at once and operate as the Hartford division of the West Bend plant.

•

The Perfex Corp., Milwaukee, has received government approval for an addition to its main plant to cost $85,000 and increase present floor area about 15 per cent.

6" Ajax machine forging sockets in two ends of female member of Di-Lok Chain

Greater Achievements Require Greater Production From

HEAVY-DUTY FORGING MACHINES

★ Industrial Progress in almost every field of manufacture is requiring products of greater strength and toughness that can be produced to close tolerances on a high production basis. Forgings provide the great strength required, due to the grain flow being refined and shaped to the contour of the product in the forging die.

Uniformity, at a high degree of accuracy, is provided by AJAX Forging Machines due to their sound mechanical construction embodying many exclusive, patented features.

High speed production on AJAX machines is accomplished by the patented direct acting air clutch providing instantaneous response to the operation of the treadle.

Forgings such as these illustrated are being produced on AJAX Forging Machines faster, better and at less cost for manufacturers of ships, airplanes, trucks, tractors, tanks, diesels, ordnance, locomotives, agricultural machinery and other products.

● Two years of experience with the NIAGARA *AERO* HEAT EXCHANGER as used to cool water and oil quenching baths for heat treating has proven that more accurate control of temperature pays extra dividends.

First installed by many users because it saved nearly all the cost of cooling water and the attendant piping and pumping costs, it has proved to these same users that its greatest value is in improving and increasing production by assuring more uniform, reliable operations, with more accurate hardening results and greatly decreased rejections because of more accurate control of temperatures.

If you have a problem of cooling any industrial liquid to controlled temperatures—as in quenching, machining, grinding or wire drawing coolants, or in chemicals or intermediates, or in equipment or engine jacket water, or in air compressor cooling to keep water and oil out of the lines, the NIAGARA *AERO* HEAT EXCHANGER provides accurate temperature control at lower cost.

WPB Stops Blanket Construction Approvals

• • • **Blanket authorizations,** which have been used to permit owners of substantial industrial and commercial establishments to carry on miscellaneous routine construction during a fixed period, will no longer be issued generally, WPB announced in issuing Direction 3 to Conservation Order L-41. Such blanket authorizations will be issued hereafter only in cases where the filing of individual project applications would interfere with the war effort or cause extreme hardship to the applicant.

The necessity for blanket construction authorizations has been for the most part eliminated by (1) the recent transfer of jurisdiction over applications involving $25,000 or less to WPB field offices, (2) by simplification of WPB application procedures under Direction No. 1 to CMP Regulation No. 6, and (3) by the exception of certain types of minor capital additions from the Order L-41 construction authorization requirement.

In cases where blanket authorizations may be justified, application will be made as at present on WPB form 617 and filed with the WPB field office for projects less than $25,000; and filed with the War Production Board, Washington, D. C., if $25,000 or more. A person seeking blanket authorization, will prepare his application in the same way he would prepare it for a single job, in accordance with instructions in WPB form 617.

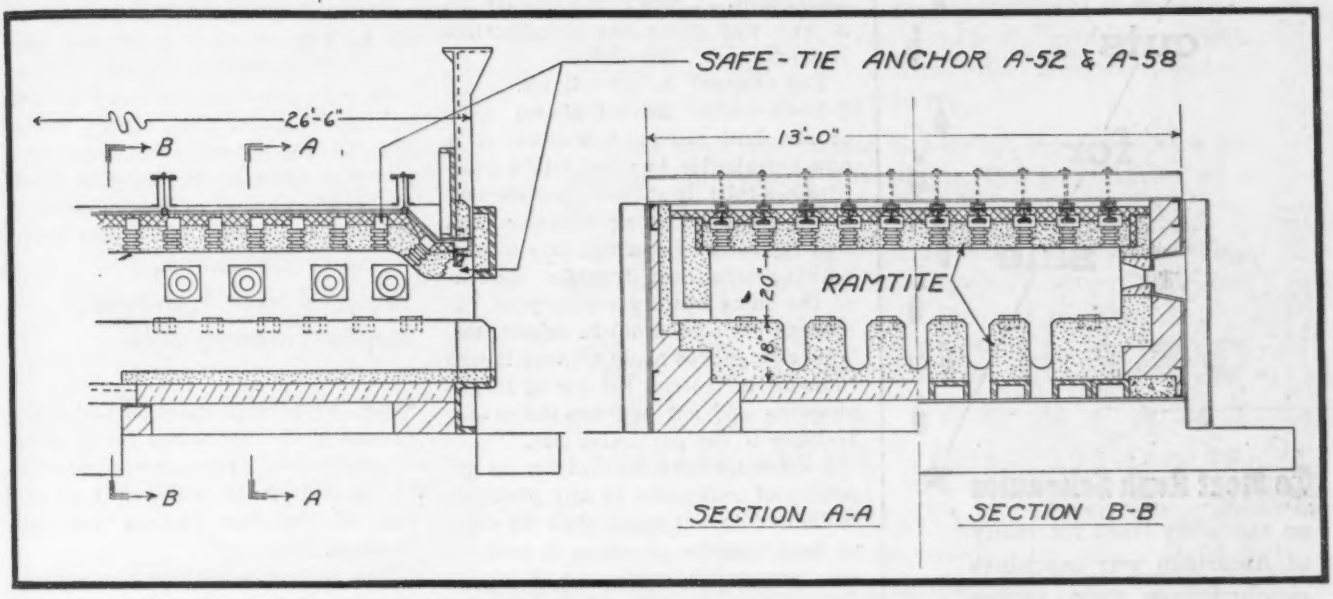
Blanket authorizations will permit the builder to do miscellaneous routine construction, but no materials may be acquired or used contrary to limitations that will be made a part of the authorization. In the case of equipment items that must be listed on the application, the builder may use only those which are specifically approved. The use of such items or deviations from the Construction Limitations will be approved only in exceptional cases.

No job for which tax amortization privileges are requested may be included in a blanket application. A separate application is to be filed for each such job at the time the request for tax amortization is made.

The new Direction 3 to order L-41 supersedes instructions outlined in the WPB letter of instruction WPBI-43 (formerly PDL-362), which has heretofore contained the rules for the granting of blanket authorizations.

RAMTITE PRODUCTS SERVE EVERY INDUSTRY USING HEAT

Just the right refractory for PLATE HEATING FURNACES



YES—Ramtite is the right refractory for plate heating furnaces . . . Because:

1. Its high refractoriness guarantees long trouble-free lining service.
2. Its monolithic surface plus good insulating value makes accurate furnace temperatures easily controlled.
3. To build a furnace of similar design with prefired shapes would be difficult, if not impossible. But, Ramtite is installed while plastic, so construction of well-engineered furnace design is easy.

Send for a bulletin describing the engineering properties of Ramtite.

Manufacturing Limits Eased on Unit Heaters

Washington

• • • To eliminate unnecessary hardship on manufacturers of unit heaters and convectors, WPB announced an amendment to schedule I to order L-107, Extended Surface Heating Equipment. Today's changes do not in any way relax the simplification restrictions of the order.

The changes are as follows:

1—In larger housed blower units of standard size unit heaters, it is now permissible to substitute a tube-within-a-tube heat transfer element of no greater heating capacity than that replaced. Formerly, only a tube-within-a-tube heat transfer element of the same heating capacity as the element replaced could be substituted. This change was made because it was intended to restrict the use of larger elements and not to limit the manufacturer to one particular size.

2—Manufacture, fabrication or assembly of convectors by any producer is limited to not more than 20 sizes of heat transfer elements in each of the permissible depths (6, 8 or 12 in.). A convector is a heat transfer element enclosed in a cabinet that serves as a stack to accelerate the circulation of air through the heating element. Previously, the producer was limited to not more than 20 sizes as determined by the rated equivalent direct radiation capacity. This change will permit manufacturers to make units of different measurements provided they do not involve more than 20 sizes in each depth.

3—Recessed or semi-recessed cabinets for convectors for use in hospitals for mentally disturbed patients may now be produced. Formerly, only wall and free-standing cabinets were permitted.

Order L-107 itself was also amended to remove those provisions that made it possible to schedule production of extended surface heating equipment under this order. Order M-293 is the general scheduling order and if it becomes necessary to schedule production of this equipment it can be accomplished under that order.

COMING EVENTS

March 27, 28—American Society of Tool Engineers, Philadelphia.

March 30, 31—American Gas Association War Conference, Rochester, N. Y.

Shipyard First Approved Surplus Property Sale

Washington

• • • The first transaction under the government's new setup for disposal of surplus war property was recorded in the sale by the Maritime Commission of the San Jacinto shipyard, Houston, Tex.

The sale was approved by W. L. Clayton, Surplus War Property Administrator, and was the first announced deal to cross his desk since his appointment two weeks ago.

The shipyard was sold to E. I. du Pont de Nemours & Co. for $200,000, described as a price substantially in excess of the value placed on the property by an independent appraiser retained by the government.

Du Pont will adapt the plant for the preparation of phenothiazine.

OPA Permits Installation Charges for Pressure Vessels

• • • The provision of the regulation setting maximum prices for used storage vessels which allows sellers to charge a portion of the original installation cost, when in excess of $100, has been amended to include all vessels listed in that regulation. These vessels include some 2600 sizes and combinations of used pressure vessels and used enclosed atmospheric pressure vessels—cylindrical tanks made of black steel and used for holding gas or liquids. This change was made in amendment 2 to MPR 465 by OPA.

It was the original intention when the compensation-for-installation provision was put into effect Jan. 5, 1944, to include all tanks covered by the regulation. Through an oversight, one group was omitted.

"PUT IT ON THE BLANCHARD"

CHECK THESE ADVANTAGES OF BLANCHARD GRINDING

- Production
- ★ Adaptability
- Fixture Saving
- Operation Saving
- Material Saving
- Fine Finish
- ★ Flatness
- ★ Close Limits

★ . . . . . *Especially valuable on jobs like the one illustrated.*

HERE are two surface grinding problems that came to the Blanchard Engineering Department in one week:

(1) Grind a hardened steel ring 86½" in diameter to a tolerance of ±.0002" for thickness.

(2) Grind the edges of a steel strip, .005" thick, .125" wide, and 20" long, straight and to a tolerance of ±.0005".

Thirty years experience in grinding flat surfaces enabled Blanchard Engineers to solve the grinding of both of these jobs, using Blanchard vertical Surface Grinders and Blanchard Grinding Wheels.

If you have work which lies within the range here indicated, you should investigate the possibilities of a Blanchard.

Whether the job is large or small, usual or unusual, Blanchard can show you how to grind it better and faster.

Steel Payrolls Total $141,794,000 in Jan.

• • • Payrolls of the steel industry rose in January to $141,794,000 over December, 1943, which totaled $140,203,000. In January 1943 they amounted to $129,760,000.

Average number of employees at work in the industry throughout the month amounted to 583,000. Wage earners averaged 116.5c. per hr. for the month compared with 116.1c. per hr. in December, 1943, and worked an average of 45.7 hr. per week, as against 43.2 hr. in December, 1943.

Construction Machinery Repairs Parts Order Eased

Washington

• • • Restrictions on the purchase of repair parts for construction machinery and equipment were eased by WPB by amending order L-192. Parts for current use may now be purchased by certification by the purchaser instead of through application for WPB authorization, with the exception of purchase orders of more than $1000 for parts for shovels, cranes and draglines of less than 2½ cu. yd. capacity. Such purchase orders are subject to WPB authorization.

Approximately 85 per cent of all new construction equipment is needed to fill military requirements, the WPB Construction Machinery Division said. This means that used equipment must take care of civilian needs. It has therefore been found advisable to facilitate the purchase of repair parts required to keep the equipment in operation by relaxing restrictions insofar as possible.

Shovels, cranes and draglines are the most critical items covered by order L-192, which controls the production and distribution of specified types of construction equipment. The authorization required for repair parts' purchase orders of more than $1000 is designed to conserve parts for the most essential uses.

Certification of purchase orders requires that the repair parts ordered are needed to replace worn out parts within 30 days after receipt and are not for stock; that the purchaser does not have other parts on hand or on order for this purpose; and that he has complied with the provisions of order L-196.

PRECISION STAMPING

for Victory

Applying its many years of experience in the production of fine metal stampings to the manufacture of War Material, The Metal Specialty Co., is completely equipped to give you efficient service in Stamping, Rolling, Coining, Forming, Drawing and Annealing in all Meals. Specialists in Hydraulic cold drawing and embossing in all metals including stainless steel. Deep drawing and embossing up to 850 tons capacity. Shells drawn up to 20" depth. Assembling including Flash and Resistance Seam Welding Pressed metal products to specification.

Order Changes Aid in Laboratory Needs

• • • Conditions under which priority assistance is given to laboratories were clarified by WPB through issuance of an amended Preference Rating Order P-43. The definition of "laboratory" now specifies that any person who carries on scientific or technological investigation, testing, development or experimentation in his business is considered to operate a laboratory in buying material for these purposes, even though he does not have a separate department in his company or institution for such activities.

Priority ratings assigned by the order may be used to get materials for development of products designed primarily for future civilian markets only if such activities will be carried on without diverting any manpower, technical skill, or facilities from war work. Laboratories that have been assigned serial numbers by WPB may not use their AA-1 preference rating for activities connected with future civilian markets.

New provisions of the amended order follow; Restrictions on the quantity of aluminum that may be obtained under the order are removed. Priorities assistance assigned under P-43 may be used for construction jobs costing not more than $500 without applying for permission to start construction under L-41. The laboratory's cost of labor and of equipment required for laboratory activities need not be included.

Hand tools and safety equipment bought by a laboratory for resale to its employes for use in the laboratory's activities may be obtained under the order. Procedure for obtaining controlled materials has been simplified, and the allotment number V-9 is used in place of MRO-P-43. A new procedure for obtaining Class A products is set up and described.

Even though machinery or facilities include new features or developments, material for their production cannot be obtained under the order if they are intended for use in the manufacture of commercial products.

ARMCO Earns $6,098,074

Middletown, Ohio

• • • The American Rolling Mill Co., for 1943 reported a consolidated net income of $6,098,074, compared with net income of $7,780,988 in 1942. Net sales in 1943 amounted to $199,266,466 compared with $180,978,867 in 1942.

STRENES METAL
IN FRONT LINE OF SERVICE

BEFORE THE WAR

Strenes can be cast to shape. Most of the usual machining time is saved. Redressing is reduced. That is why before the war Strenes gained heavily as forming and drawing die metal. In one case around 2,000,000 stampings were obtained and the die is still in good condition, ready to resume operation at the end of the war. Runs of 100,000 pieces up are not uncommon. Hundreds of the largest plants in the country used it regularly in their tooling programs. Want the names of pre-war users of Strenes?

IN THE WAR

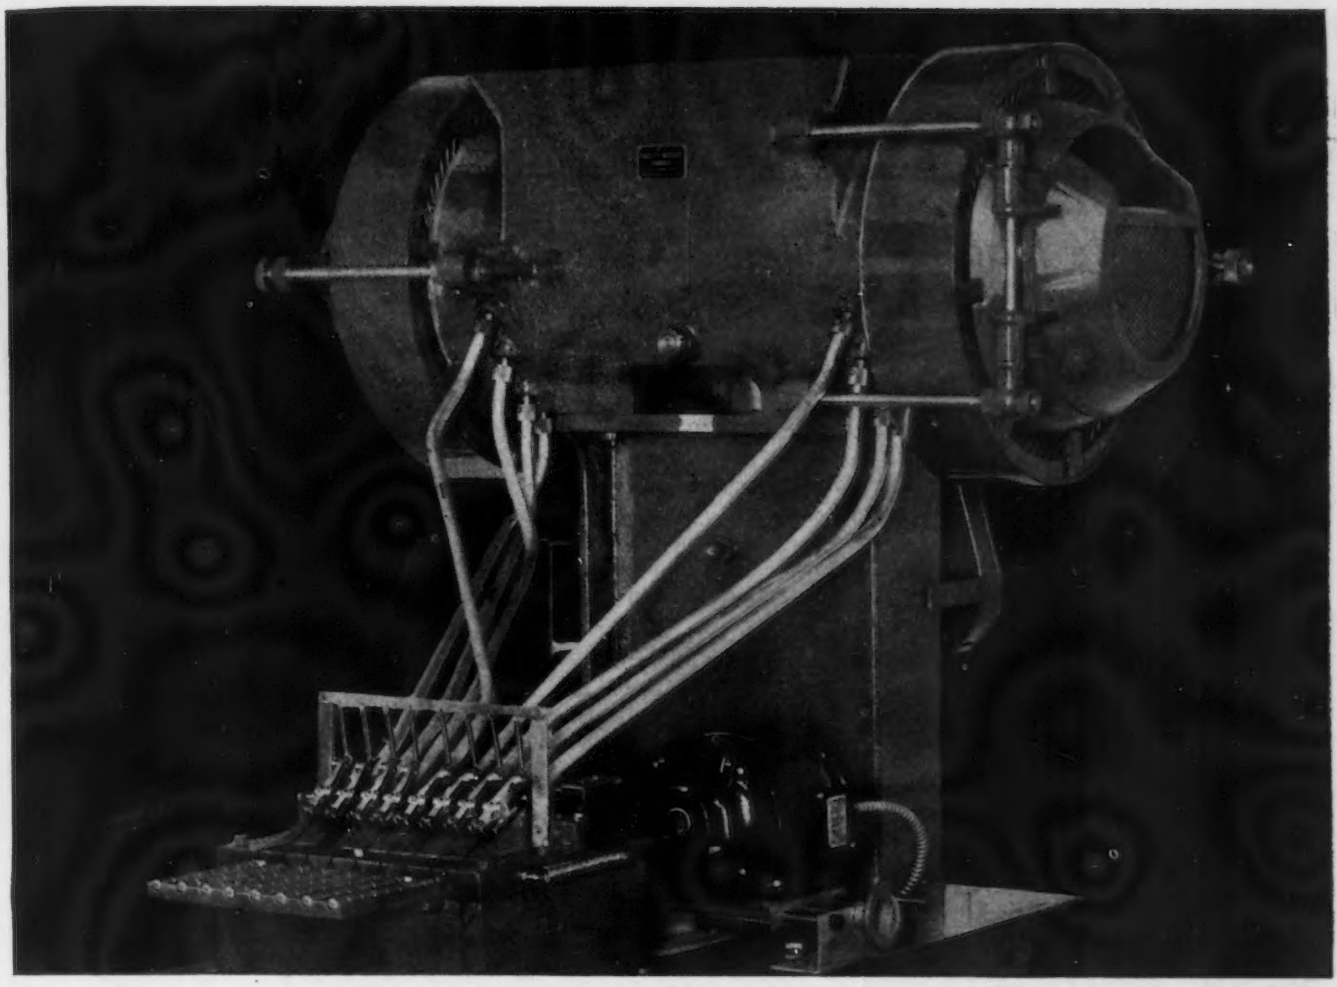
Strenes today is being used for draw pots, draw pot inserts, draw rings for draw bench operation, for progressing upsetting dies—all in shell manufacture. Glad to identify all such users and many others.

AFTER THE WAR

After the war, refrigerator, stove, metal casket, grave vault, farm implement and other manufacturers will resume with Strenes metal forming and drawing dies. Many of the automobile, truck and tractor builders are extensive users, for body, fender and hood dies. Will name them to interested inquirers.

Look into the merits of Strenes metal — Try it, at least once.

THE ADVANCE FOUNDRY CO.
DAYTON 3, OHIO



Another FIDELITY Machine — war-born with peace-time applications — perhaps for you

If you have many small metal parts which have had to be sorted and handled manually—in large quantities—you will be interested in this adaptable basic machine which FIDELITY has made in a number of variations.

The parts are dumped into a hopper from which they are fed out in single or multiple tracks, in correct position for the next process. In some cases, sequential steps are taken care of by additional mechanisms or attachments, made integral with the automatic hopper and feeder element.

The machine illustrated sorts and delivers copper slugs through eight tracks at the rate of 20 slugs per minute per track—a total of 160 per minute.... Receiving trays, platforms or troughs in such machines can generally be designed to function also as piece counters or batch boxes.

The range of FIDELITY'S developments in special machines designed and built to solve unusual and special production problems is described briefly in "Facilities."

A copy of this book is available if you write on your business letterhead.

MACHINE TOOLS

. . . News and Market Activities

Sale of Idle Machine Tools Permitted Without Priority Rating

Washington

• • • **Provisions of the recently amended Priorities Regulation 13, as they apply to the sale of idle and excess stocks of machine tools, have been clarified by the Tools Division. The rules governing "special sales" of idle and excess materials have been broadened in the regulation to include finished products, including machine tools. "Special sales" include sales of products by a person who does not sell them in the regular course of his business. List B of PR13 now provides that such special sales of machine tools may be made without any priority rating or allocation.**

Heretofore, machine tools that have been put into actual use have been obtainable on unrated purchase orders. However, new machine tools delivered to a customer, but which he did not put into use because of reduction or cancellation of contracts or for other reasons, have been subject to the restrictions of Priorities Regulation 1. That regulation provides that property acquired with a preference rating, but not used for the purpose for which the preference assistance was granted, could only be sold to persons and in ways specified by WPB.

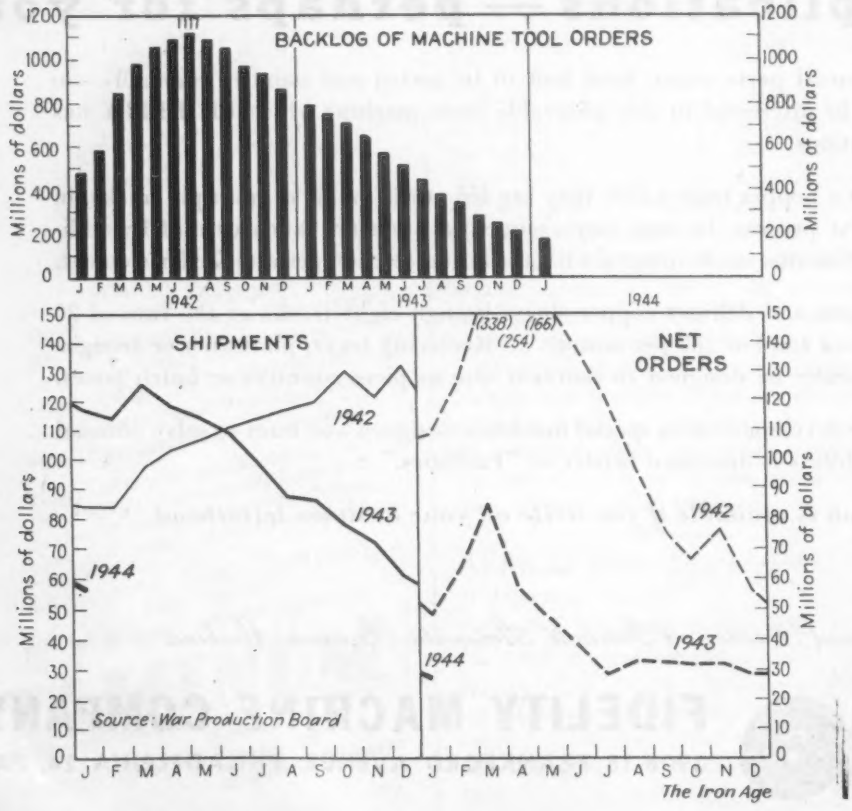
The addition of machine tools to List B of PR13 with the symbol "WOP" (without priorities) now frees such delivered but unused machine tools from the restrictions of PR1.

Sales of new machine tools by producers continue to be governed by General Preference Order E-1-b (Machine Tools). No change in Preference Order E-4 (Second Hand Machine Tools) is contemplated, the Tools Division said. The mechanism established by that order will still be used where it is desired to allocate to a particular buyer a specific used machine tool offered for sale.

No Priorities for Post-War Yet

Cincinnati

• • • **District machine tool manufacturers indicate that there continues to be a modest flow of new business, but otherwise the market is without interesting feature. Recent apparent pressure on WPB to ease priority requirements to allow manufacturers to manufacture and deliver some post-war material brought a stern warning from local WPB officials that they had no objection to manufacturers considering post-war business, but that no priorities would be issued for any of this type of production. In the meantime, manufacturers indicate that renegotiation conferences have reached conclusions and in most instances companies have set up agreements on the controversy, with some payments having been reported.**



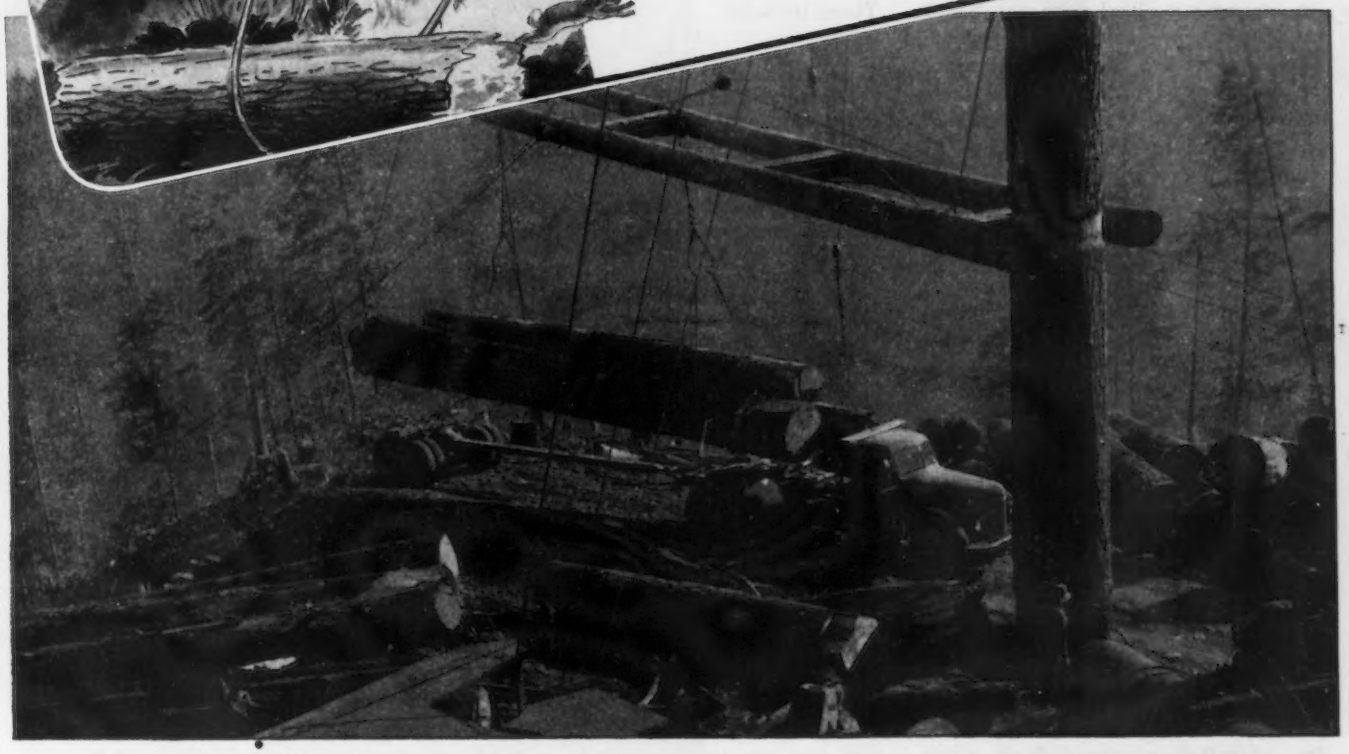
Machine Tool Orders and Shipments Off

• • • **Machine tool shipments in January declined about 7.5 per cent from December, 1943, to a value of $56,349,000 according to the final report for these months by the WPB Tools Division. December shipments were valued at $60,861,000. Shipments have been declining almost steadily each month since December, 1942, when they totaled $131,960,000. Monthly average shipments in 1939 were valued at $16,660,000, in 1940 at $36,890,000, in 1941 at $64,290,000, in 1942 at $110,146,000, and in 1943 at $98,350,000.**

Orders placed in January totaled $29,736,000, a drop of about 12 per cent from December's total of $33,742,000. Cancellations in January declined 46.5 per cent to $3,820,000, leaving net new orders for that month of $25,916,000, or about 6 per cent less than the December total of net new orders of $27,603,000.

Backlog of unfilled orders in January declined 13.8 per cent to $181,548,000 or slightly more than three months' production at the January rate. December backlog was valued at $210,606,000.

FIRST SOLUTION OF MANPOWER SHORTAGE



Modern Multiplier of Manpower ... WIRE ROPE

Perhaps while in pursuit of food, which scampered under a fallen tree, some primitive man angrily pulled on a vine tangled around the tree and found that he would not need to call for help to move an otherwise impossible load.

In solving the first manpower shortage, this primitive no doubt wondered who pulled as hard on the other end of the vine as he did on his and little realized he had discovered the principle of the pulley.

Today, the pulley has been multiplied into the block-and-tackle and the latter rove with wire rope so strong and tough that mankind goes on hoisting and moving loads which yesterday were considered impossible.

To Union Wire Rope engineers the impossible is a constant challenge. In the finest of wire rope laboratories they work at the one job of making wire rope stronger and tougher to last longer. The tensile strength, torsional values, fatigue life, ductility, hardness of wires, etc. are predetermined. From numerous tests and checks the pedigree of every run of wire rope is recorded and then, wherever possible, its performance on the job is watched. With Union engineers wire rope making is a specialty in which they do not propose to be excelled.

FREE

Do You Need Wire? Manufacturers using high carbon steel wire functionally are invited to investigate the dependable source of supply afforded by our extensive facilities. Our engineers will submit interesting proposals on your requirements.

Truman Committee Reports on Magnesium

• • • **The Truman Committee** report on magnesium, filed with the Senate on Monday, suggested that programs for the wide use of the metal should be inaugurated promptly. The committee recommended that the WPB give immediate consideration to the elimination of its M-2 order restricting the use of magnesium to war and essential civilian items. Such action, the report stated, would constitute an important first step in carrying out the committee's principal recommendation that surplus materials be made available to all who want to use them in areas where there is no manpower shortage, providing the users are not refusing war contracts.

At the present time, there are in this country two privately owned plants and 13 plants for which the government has spent to date $370,000,000. An additional $15 million was spent for fabricating facilities. Expenditures will still be made for process improvements. In the operation of 12 of the government owned plants, $116 million has been advanced for operation expenses from which the government has received through the delivery of magnesium a return of $58 million.

Of the 13 plants constructed and operated at government expense, only six can be considered as producing above capacity and five are still below. The remainer will either be operating at or near capacity.

Although critical of Dow Chemical Co.'s prewar monopoly position, the committee appreciated the contribution of the company's "know-how." In 1939, Dow produced about 7 million lb. of magnesium and in 1940 about 12,500,000. In 1941, capacity was again increased to 15,500,000 lb. Additional facilities were established at Freeport, Tex., having a capacity of 12 million lb. annually, plus 6 million lb. annual capacity financed by the British Government. In 1941, the government provided capital for an additional 18 million lb. expansion. At Marysville, Mich., and Velasco, Tex., were erected plants having a yearly output of 72 million lb.

Reviewing the expansion program, the committee report described the various processes employed and the capacities of the facilities constructed. These include:

	Annual Capacity, lb.
Dow Process:	
Diamond Magnesium Co., Painesville, Ohio	36,000,000
International Minerals & Chemicals Corp., Austin, Tex.	24,000,000
Mathieson Process:	
Mathieson Alkali Works, Inc., Lake Charles, La.	54,000,000
Carbothermic Process:	
Permanente	28,000,000
Ferrosilicon Process:	
Ford Motor Co., Dearborn, Mich.	40,000,000
Permanente Metals Corp., Lathrop, Cal.	20,000,000
New England Lime Co., Canaan, Conn.	10,000,000
Magnesium Reduction Co., Luckey, Ohio	10,000,000
Amco Magnesium Corp., Wingdale, N. Y.	10,000,000
Electro-Metallurgical Corp., Spokane, Wash.	48,000,000
Basic Magnesium Corp.	112,000,000

While criticizing at great length the promotion and construction of the Basic Magnesium plant at Las Vegas, Nev., the report lauded the work of the Anaconda Mining Co., present operator, for its skill in finally exceeding capacity operations while reducing the cost per lb. of magnesium.

In 1943, magnesium production reached 391,000,000 lb., while an estimate of 1944 output is 531,000,000 lb. with the requirements figure set at 485,000,000 lb.

Zinc Limitations Relaxed

Washington

• • • **Restoration of the use** of zinc in the manufacture of many finished products was announced by WPB last Thursday. This action, the board said, is in line with its general policy to permit the use of scarce materials if the result is to conserve material in greater demand, effect a saving in manhours or enable the manufacture of a better product.

The restoration was effected by amendment to order M-11-b to add a number of items to the list of exceptions to the limitations imposed.

Coal stokers, domestic electric ranges, dry cell batteries and portable electric lights, electric fans, mechanical pencils, motorized fire apparatus, protective coating or plating of zinc on loose leaf metal parts and units.

There will be no general increase in the output of the finished products involved, nor will there be any relaxation in the retrictions on the manufacture of the products, WPB said. End product volume and other restrictions on manufacture still remain under the controls set up by the many L orders under which they are produced.

•

Exemptions for Scrap

• • • **Companies which generate** or accumulate less than 50,000 lb. of copper and copper-base alloy scrap are no longer required to file WPB Form 452 although they must continue to comply with the provisions of Copper Order M-9 requiring the disposal of all scrap in excess of 30 days' accumulation unless such accumulation aggregates less than 10,000 lb.

BALDWIN SERVES THE NATION . . .

Every "Standard" Casting has a Past and a *Future*

Some of the *experience* that helps produce every Standard casting goes clear back to the days of the individual craftsman at Freedom Forge, before the Revolution. And *some of it* has been gained in the day-to-day production of the largest and most complicated shapes, every one a challenge to the highest skill of the foundryman.

There is some of this "past" in every Standard Casting, no matter how small or simple . . . and so each Standard Casting has a bit more "future" in the way of service and satisfaction. At Standard, we are equipped to handle all of your casting and forging needs. The Baldwin Locomotive Works, Standard Steel Works Division, Burnham, Pennsylvania, U. S. A.

BALDWIN PRODUCTS

Hydraulic presses • Testing equipment • Steel forgings and castings • Diesel-electric locomotives • Diesel engines • Metal plate fabrication • Rolled steel rings • Bronze castings • Heavy machine work • Crane wheels • Bending rolls • Plate planers • Babbitt metal • Alloy iron castings • Briquetting presses.

● All the facilities and resources at Wisconsin Steel are keyed to one objective today—*the winning of the war.* Our steels are produced to meet exacting specifications.

If you have an alloy steel problem, we invite you to discuss it with us and to avail yourself of the services of our staff of skilled metallurgists. Our knowledge of alloy steels—and how a specific use or application may help you meet your wartime production schedule—is at your service.

Wisconsin alloy steels meet every need. A record of QUALITY manufacture stands behind them as your assurance of user satisfaction.

SCRAP

. . . News and Market Activities

WPB Committee Protests Claims Of Scrap Sufficiency and Weak Prices

Washington

• • • **Protesting general reactions** to current weaknesses in the scrap market, the Iron and Steel Scrap Industry Advisory Committee of WPB recently asserted that scrap shortages still exist in the major grades and that current reports on market conditions and the attitude of consumers will work a detriment to the war effort. Scrap supplies, the committee reports, are at a 2.4 month level, down from three months' supply last Summer, and if inventories should fall further, furnaces may have to go down.

A review of steel requirements for the next six months indicates that production of carbon steel must be maintained at utmost capacity. Consequently scrap needs will remain at least at present levels. "The prevalent opinion," states the report, "among steel mills that there is a surplus of scrap in the United States is absolutely erroneous and is probably founded upon assistance from the WPB Steel Division in directing the flow of scrap. England has returned to the market for a portion of the overseas scrap that has heretofore flowed to the United States."

From the standpoint of alloy grades, despite the excess of supply over demand, alloy is not entirely free yet, the report claimed. Industry must continue to cooperate if the unbalance in steel scrap is to be overcome and if pressure for removal of the segregation order is to be avoided. If the order is removed, producers who cannot dispose of the alloy scrap will mix it, with the result that carbon steels will become contaminated and specifications will not be met.

There is no question that the need for uncontaminated carbon steel scrap of good quality will remain great until the end of the war and the supply will have difficulty meeting demands. However, WPB's committee overlooks the fact that surpluses in specific grades in specific localities do occur, and dealers offer such scrap at below-ceiling prices to get rid of it.

The charge that mills have notified dealers that they will refuse to buy except at certain prices or freight rates and that mills are cutting inventories is undoubtedly true, but it is believed that the former charge is true with regard to specific grades. The fact that mills request allocations of scrap when their PD forms show they have inventories because such inventories are out of balance indicates there are shortages of scrap and also indicates that some grades are in sufficient supply. This shouldn't cause too much concern, since it is basically sound not to stock material that cannot be used within a reasonable length of time. The charges are related because one results from the other. Refusal to pay ceiling prices for any scrap grade results from surpluses of that grade.

The extent of price breaks in the tool steel and stainless steel scrap markets are described on page 108.

There can be no denying that definite weaknesses have occurred at various points for such grades as low phos, shoveling turnings, machine shop turnings, mixed borings and turnings, alloy turnings, tool steel, bushelings and stainless. All the talk in the world of shortages will not alleviate these particular conditions, because mills definitely cannot utilize these grades in the quantities they are accumulating. Likewise, when a mill feels that its scrap inventories are at a desired limit, regardless of the reason, that mill will stop buying.

It is not sufficient for WPB to say these conditions shouldn't exist because of shortages in the major carbon scrap grades, because the conditions do exist and little or nothing can be done about it unless "floor prices" are established. Then what little is now sold would cease moving entirely.

•

NEW YORK — Scrap purchases are slower in this area, with much of what normally has been low phos being thrown into open hearth grade shipments. This is hoped to have a two-fold effect, bettering open hearth scrap quality and tightening up a loose situation in low phos. However, dealers are still offering it at under ceiling prices. Some 900 tons of imported scrap, mainly battle scrap, came through New York this week. Additional shipments of battle scrap have also been received at other Atlantic seaboard ports.

•

PITTSBURGH—Despite high steel operating rate, scrap supplies appear in good balance here. Alloy scrap is still being sold minus part or all of the alloy premiums.

•

CINCINNATI — Foundry cast and standard open hearth steel scrap are both in strong positions in the southern Ohio district, but some weakness is developing in the foundry steel grades. Dealers admit some sales under ceiling on borings and turnings, particularly out of the district, where buyers refuse to pay higher freight rates and the ceiling price at the same time. Consequently, borings and turnings for out-of-district shipment are reported selling $1 to $2 under the ceiling. Alloy turnings on out-of-district sales are selling f.o.b. Cincinnati $3 under ceiling. Sales within the district, however, are reported holding rigidly to current rate schedules with most consumers fairly well supplied.

•

BUFFALO—There is little scrap in dealer yards here and most items are moving readily. One dealer started the month with less than 400 tons in sight. Low phos, reported down $1 in New York, is being taken at the ceiling and there has been no shading of prices on blast furnace items, as in Cleveland and Detroit. Trade talk is that a serious shortage of scrap may develop at the end of the year if the war goes into 1945.

•

BIRMINGHAM — Open hearth grades currently are leading other grades in demand here, but consumers are paying base price only for this material. They will not absorb springboard allowances of $2. Consumers of cast grades are reported out of the market.

•

BOSTON—A slight increase in supplies of turnings and light scrap is reported. Shipments to consumers are slow due to labor shortages, but one large yard has stepped up forwardings of producers scrap. As for yard scrap, this firm is doing little. Chemical borings are wanted, but scarce. Shortage of cast iron scrap is critical. Industrial plants are not dismantling machinery these days. Here and there a yard has 50 or 75 tons, but has no help to break up cast.

•

CHICAGO—Weakness noted in short shoveling turnings a fortnight ago has filtered down through other blast furnace grades with reflection in brokers offering prices. Undoubtedly any future sales to mills will confirm this tendency.

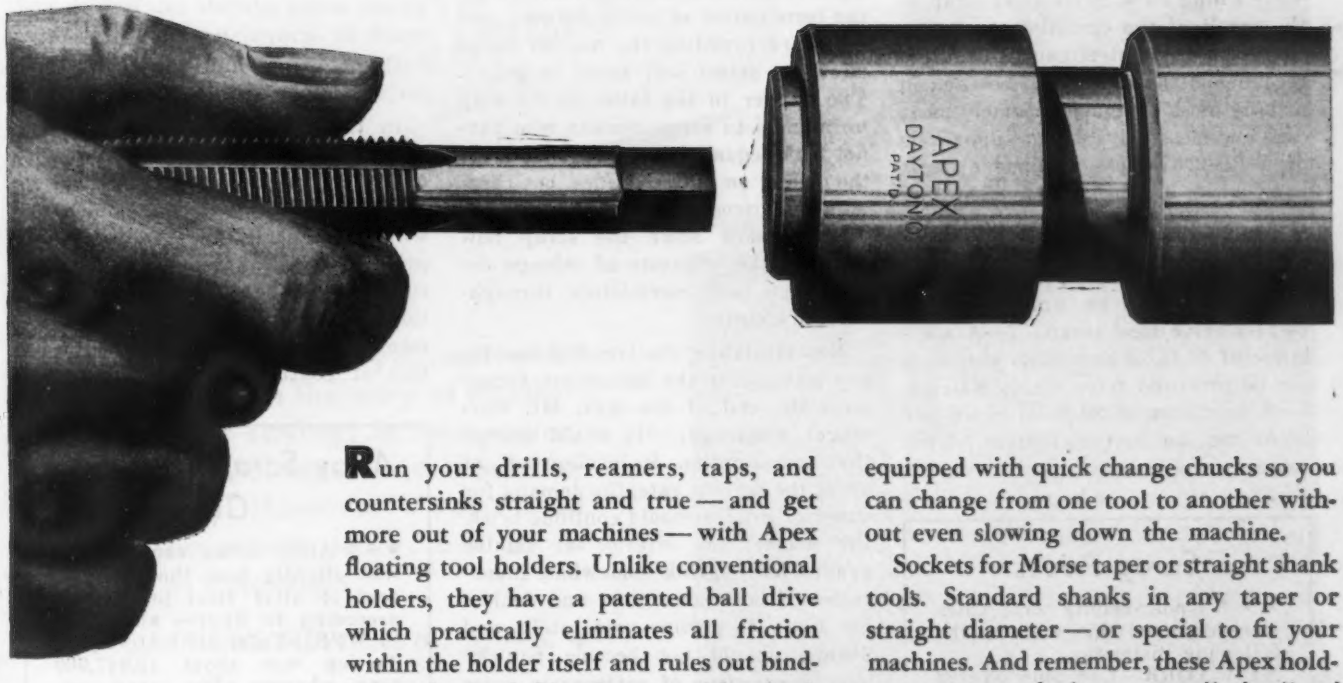
•

DETROIT—Blast furnace grades are unchanged from last week. Short turnings are selling around $1 below ceiling with scattered sales farther below. The

Drill, Ream, Tap, Countersink

More Accurately

with Apex Floating Tool Holders Equipped with Drill Chuck Bottoms!



Run your drills, reamers, taps, and countersinks straight and true — and get more out of your machines — with Apex floating tool holders. Unlike conventional holders, they have a patented ball drive which practically eliminates all friction within the holder itself and rules out binding under load. Use them on either horizontal or vertical spindles. Buy them equipped with quick change chucks so you can change from one tool to another without even slowing down the machine.

Sockets for Morse taper or straight shank tools. Standard shanks in any taper or straight diameter — or special to fit your machines. And remember, these Apex holders are a part of a large, versatile family of production tools. Write for Catalog No. 14.

APEX

THE APEX MACHINE & TOOL CO., DAYTON, OHIO

Manufacturers of Safety Friction Tapping Chucks, Quick Change and Positive Drive Drill Chucks, Vertical Float Tapping Chucks, Parallel Floating Tool Holders, Power Bits for Phillips, Slotted Head and Clutch Head Screws, Hand Drivers for Phillips and Clutch Head Screws, Aircraft Universal Joints, Plain and Universal Joint Socket Wrenches.

alloy situation is slightly improved, but alloy scrap of all kinds is still going at the base price plus nothing for alloy content or at most, half the allowed premium.

•

PHILADELPHIA — Little change has taken place this week. Shipments appear adequate although little scrap is moving out of the yards. A boatload of scrap from the south arrived here for Bethlehem. Shipments of foundry cast have slowed up considerably. Little if any can be had. Although heavy open hearth grades are in good demand, there is weakness in turnings.

•

ST. LOUIS—Receipts of scrap in this area are still below requirements, one reason being the absence of peddlers and truckers to move accumulations to yards. Mills need carbon steel scrap free of alloys. Railroad movement is hampered by shortage of men to handle material.

Stainless Valve Scrap Approved for Mess Equipment

Washington

• • • **Piling up of valve** steel scrap as the result of the curtailment of purchases of valve steel caused WPB to recommend that the scrap be used in making mess equipment, namely meat cans and mess trays. Future approvals of WPB-2933 mess equipment items upon which the use of modified 18-8 (type 302W) stainless has been approved, will require that in melting: 1—A minimum of 50 per cent of the contained nickel be procured from 14-14-2 valve steel scrap. 2—A maximum of 40 lb. of chromium per ingot ton be procured from virgin sources. 3—A maximum of 20 lb. of nickel per ingot ton be procured from virgin sources.

Scrap Prices

• • • **Under-ceiling scrap sales were reported this week in the following districts:**

NEW YORK—Low phos offered at $1 under ceiling.

CINCINNATI—Out of district shipments of borings and turnings at $1 to $2 under ceiling.

CINCINNATI—Out of district sales of alloy turnings sell f.o.b. Cincinnati at $3 under ceiling.

BIRMINGHAM—Consumers refuse to pay springboard allowance of $2 on various grades carrying this premium.

GENERAL—Special tool steel and stainless steel scrap going at prices far below ceilings in many districts and other districts report that sales are practically nonexistent.

Barringer Warns Against Under-Ceiling Sales; Reports on Future

Montreal

• • • **At the meeting** of the Canadian Secondary Materials Association, Edwin C. Barringer, president and executive secretary of the Institute of Scrap Iron & Steel, Inc., made some pertinent remarks with regard to the future trends in secondary and scrap materials. He emphasized the shortage of preferred base grades, such as heavier grades of carbon steel scrap for open hearths and cast iron grades, pointing out that if open hearth furnace operations through 1944 are at current rates, definite shortages of such scrap will result by the end of the year.

With regard to inventories and prices, he said that it is known that some consumers are considering reducing inventories as a precaution against the termination of war contracts, and some are prodding the market in an effort to detect soft spots in prices. The danger in the latter is not only unfairness to scrap dealers who cannot make equalizing adjustments over the ceiling on scarce grades, but pressure on prices by consumers will inevitably slow down the scrap flow and sap the interests of salvage departments and committees throughout the country.

Recapitulating the trend in secondary metals for the immediate future until the end of the war, Mr. Barringer remarked: "It would appear that consumption is leveling off at about the current rate, the demand for superior grades should continue brisk, the market for inferior or lighter grades may shrink somewhat, inventories of both consumers and dealers are likely to decline moderately, and dealers should not become panicky over suggestions of softness in price but resist them as impeding a necessary sustained flow of material.

If the German war ends before the Japanese war, production of war material may be cut by 33 to 50 per cent. While land fighting was originally expected to almost cease with the end of the German war, experts now believe that the Japanese army must be defeated, and China seems the logical base for such operations. In such an event, production of material would not shrink back entirely to air and Navy equipment, but would round off the termination of contracts in better fashion for many industries. However conditions may develop, the end of the German war will sharply reduce production and scrap consumption will likely drop to an extremely low level while industrial and factory scrap, which is about 50 per cent of all purchased scrap, will still be coming into the market in substantial volume. This will offset the shortages of strictly dealer scrap but will work to a disadvantage on dealers in small communities and to the relative advantage of dealers in large industrial centers.

A variable in the postwar period is the increased flow of obsolete material and idle or excess inventories. An orderly liquidation of these surpluses appears prudent, but, if making work after the war is the major consideration, the recycling of surpluses would provide much work and result in scrapping only of the original man-hours and not of the material itself.

In the immediate postwar period, outpouring of secondary materials will be substantial while consumption will be greatly reduced and demand will be practically nil. If government price controls are relaxed, price fluctuations may be terrifying and agitation can be expected for the establishment of a price floor and a continuation of controls.

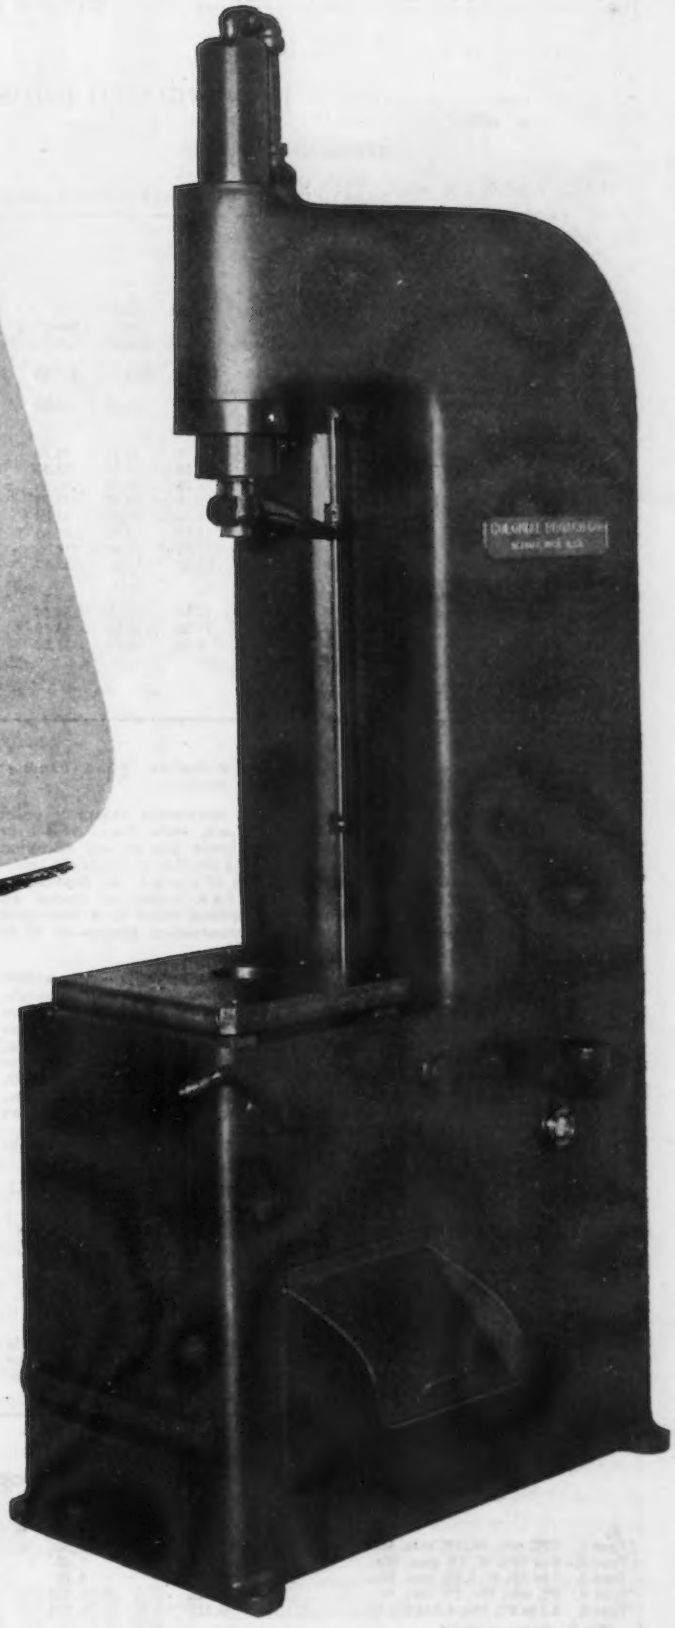
Alloy Scrap Consumption

• • • **Alloy scrap consumption was slightly less than 44 per cent of alloy steel production, according to figures attributed to WPB. Total alloy steel production was about 13,047,000 tons, whereas alloy scrap consumption, including home scrap, was 5,724,000 net tons.**

Monthly alloy steel production and alloy scrap consumption were as follows:

Month	Alloy Steel Production, Net Tons	Alloy Scrap Consumption, Net Tons
January	1,224,000	456,000
February	1,165,000	428,000
March	1,264,000	493,000
April	1,193,000	500,000
May	1,196,000	534,000
June	1,081,000	493,000
July	1,077,000	502,000
August	1,107,000	514,000
September	1,034,000	475,000
October	999,000	477,000
November	891,000	432,000
December	816,000	420,000

11 COLONIAL SURFACE BROACHING MACHINES *now do the job of* 60 MILLING MACHINES *in producing* 66 DIFFERENT PARTS *in* 13 OPERATIONS EACH



You can figure for yourself what that means in the way of flexibility and of savings in manpower, capital investment and manufacturing cost. However, if you would like the whole story, ask for a copy of Colonial's

BROACHING NEWS, Vol. 5, No. 4

(Right) One of the most flexible of machines, this Utility Press—one of the machine types referred to above—may be used for both broaching and other types of press work. It is thus well adapted to the requirements of the smaller or medium-sized shop as well as where higher production is required.

* Baled turnings are $5 per gross ton higher.

BUNDLES: Tin can bundles are $4 below dealers' No. 2 bundles; No. 3 bundles are $2 less than No. 1 heavy melting.

AT NEW YORK CITY or Brooklyn, the maximum shipping point price is $15.33 for No. 1 heavy melting, f.o.b. cars, f.a.s. vessel or loaded on truck. Minimum set at $14 per gross ton at any shipping point in U. S. Other grades carry differentials similar to those in table. New Jersey prices must be computed on basis of all-rail. At Boston the maximum is $15.05 for No. 1 f.o.b. cars, f.a.s. vessel or loaded on trucks. Shipments from a New England shipping point to a consumer outside New England carry maximum transportation charge of $6.66 per ton.

SWITCHING CHARGES: Deductions for shipping points within basing point (cents per gross ton) are: Chicago, 84c.; Pittsburgh, Brackenridge, 55c.; Detroit, 53c.; Midland, Johnstown, Sharon, Youngstown, Warren, Weirton, Cleveland, Toledo, Los Angeles, San Francisco, Pittsburg, 42c.; Seattle, 38c.; Buffalo, Claymont, Harrisburg, 36c.; Atlanta, Birmingham, 32c.; Butler, Monessen, Canton, Steubenville, Cincinnati*, Portsmouth, Ashland, Coatesville, Phoenixville, Bethlehem, Kokomo, Duluth and St. Louis, 28c.; Alabama City, Ala., 26c.; Minnequa, Colo., 22c.; Middletown, 14c.; Conshohocken, Sparrows Point, 11c.

*Basic open hearth and foundry grades, and auto springs and crankshafts, deduct 80c. per ton.

BASING POINT includes switching districts of city named.

Basing point	Switching districts:
Pittsburgh	Bessemer, Homestead, Duquesne, Munhall, McKeesport
Cincinnati	Newport
St. Louis	Granite City, E. St. Louis, Madison, Ill.
Chicago	Gary
Claymont	Chester, Pa.
San Francisco	So. San Francisco, Niles, Oakland

MAXIMUM SHIPPING POINT PRICE: Where shipment is wholly or partially by rail or vessel, or combination of rail and vessel, the scrap is at shipping point when placed f.o.b. railroad or f.a.s. vessel. For motor vehicle shipments scrap is at shipping point when loaded. Then maximum shipping point price shall be: (a) For shipping point located within a basing point, prices shown in above table for scrap at basing point in which shipping point is located, minus applicable switching charge deduction shown in paragraph above labeled "Switching Charges." (b) For shipping points outside basing point, price listed in above table hereof for scrap at most favorable basing point, minus lowest charge for transportation from shipping point to such basing point by rail or water carrier or combination. Where vessel movement is involved, in lieu of established dock charge or any cost customarily incurred at the dock, 75c. per ton must be included as part of deduction in computing shipping point price; 50c. at Memphis; $1 at Great Lakes ports; and $1.25 at New England ports. If no established transportation rate exists for a portion of movement from shipping to basing point, actual charge or cost customarily incurred by shipper in such portion of movement shall be included as part of deduction in computing shipping point price. For exceptions see official order.

UNPREPARED SCRAP: For unprepared scrap, maximum prices shall be $3.50 (and in the case of the material from which No. 1, No. 2, and No. 3 bundles are made $4) less maximum prices for the corresponding prepared scrap. In no case, however, shall electric furnace, acid open hearth and foundry grades be used as the corresponding prepared scrap. A preparation-in-transit charge for unprepared scrap is provided.

NEW LISTED GRADES: Priced in dollars per gross ton less than No. 1 heavy melting steel. Pit scrap, ladle skulls, slag reclaim, etc., of 85% or more Fe priced less $2; 75 to 85% Fe less $4; under 75% Fe less $8 per ton. Mill scale less $8 per ton. Mill cinder and grindings, shipping point maximum price of $4 per gross ton at all U. S. shipping points.

CHEMICAL BORINGS: No. 1 (new, clean, containing not more than 1% oil), $1 less than No. 1 heavy melting; No. 2 (new, clean, containing not more than 1.5% oil), $2 less than No. 1 heavy melting. If loaded in box cars add 75c. mill scale, $8 less than No. 1 heavy melting.

Tool Steel Scrap Prices (MPR 379)

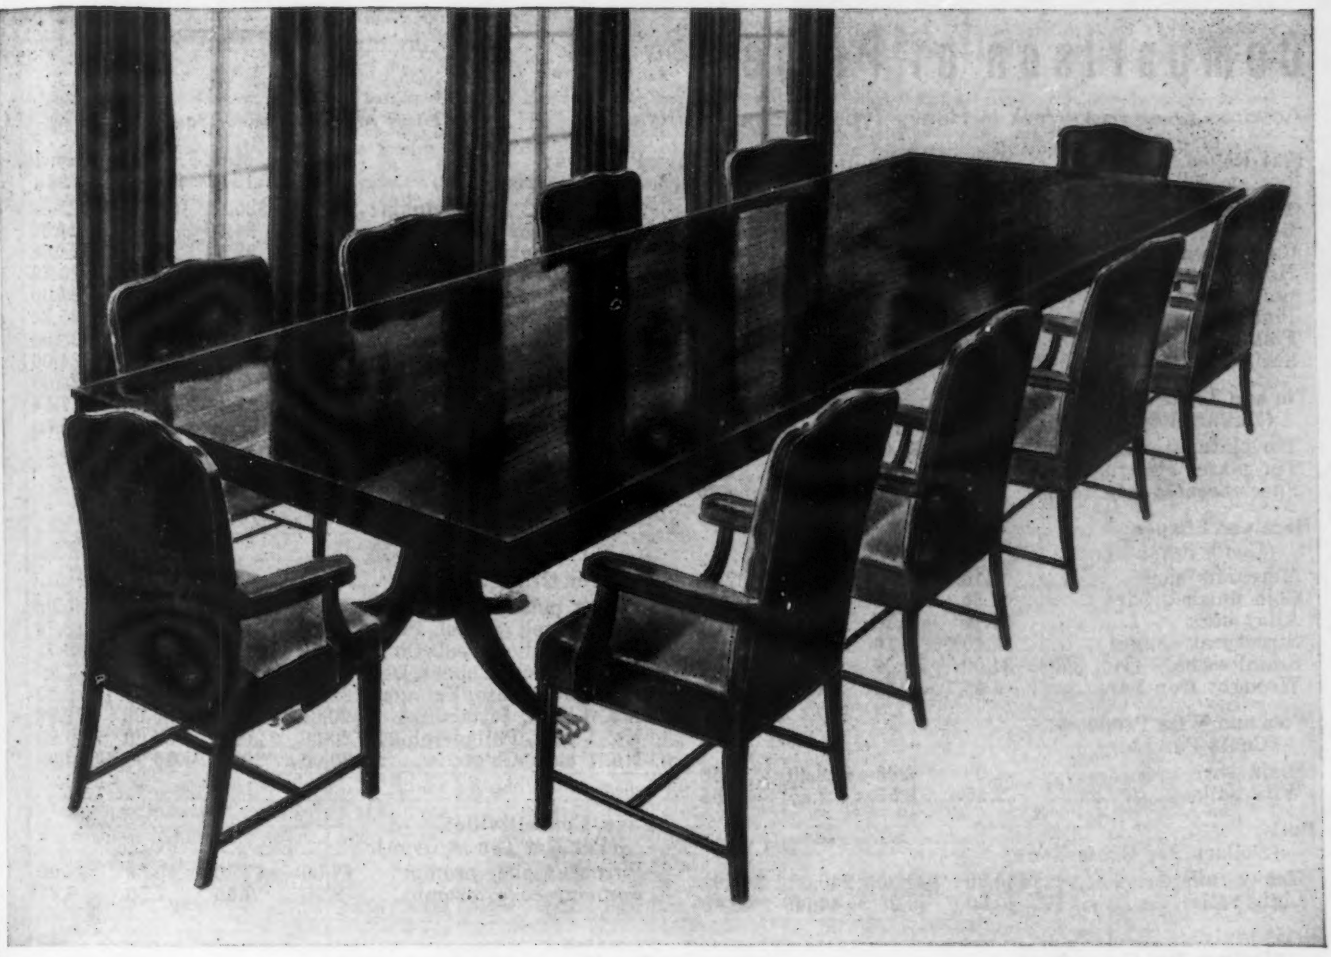
	SEGREGATED Solids Per Lb. Cont. W	SEGREGATED Turnings Per Lb. Cont. W
Type 1. 12% min. W, 1% max. Mo	$1.80	$1.60
Type 2. 5 to 12% W, 1% max. Mo	1.60	1.40
Type 3. 1 to 5% W, 1.5% max. Mo	1.25	1.25
*Type 4. 7% min. Mo, 2% max. W	0.125	0.105
*Type 5. 3.5 to 6% Mo, 4.5 to 6% W	0.135	0.115

UNSEGREGATED SOLIDS	UNSEGREGATED TURNINGS
$1.50 per lb. contained W if 5% or more.	$1.30 per lb. contained W if 5% or more.
$1.15 per lb. contained W if 1 to 5%.	$1.00 per lb. contained W if 1 to 5%.
$0.80 per lb. contained Mo if 1.5% or more.	$0.70 per lb. contained Mo if 1.5% or more.

If both W and Mo are within ranges, payment may be for both W and Mo content.

*Per lb. of scrap material.
If segregated, a premium of $1.50 per lb. of contained Co allowed if Co content is 3% or over. No scrap considered segregated if Co content ranges between 0.5 and 3%.
If Cu or Ni content over 0.25%, price shall be reduced by 50%.
If 500 lb. or less is sold, either segregated or unsegregated, price shall be reduced 2c. per lb. of scrap material.

Price schedules on railroad scrap and cast iron scrap will be carried in the last issue of each month.



LET'S HOLD A PEACE CONFERENCE—NOW

The public, during war times, may be content to go without your products. But it is quite possible that consumers may not want to wait too long for them after peace comes. Quick production of your products at that time may require "outside" manufacture of machine tooled parts or even of complete mechanisms.

So why not hold a "peace conference," in advance of peace, where, if you please, we can be invited in to discuss your future plans to produce civilian goods? It might be of great importance to you in speeding production later when delivery to market is urgent.

It's true we can not take contracts now for immediate delivery, because of our serving the Army and the Navy, as we have been for over twenty years. The Army-Navy "E" and four stars have been awarded to Pollak for continued high achievements in the production of bomb racks, bomb shackles, fuzes and other war equipment.

We will not deny that this recognition of merit for our performance for our armed services is highly gratifying to us. But unless it also indicates to our future peacetime customers that we can develop and build good products for them as well, its significance will have been lessened.

Pollak has the ability, equipment and plant to develop and produce not only fine precision products but also the capacity to produce them in required quantity—and on time.

That is why we believe our executives and engineers have much to offer in the way of valuable knowledge, techniques and experience. At your suggestion they will be glad to gather around your planning-for-peacetime-products conference table—without obligation.

POLLAK
PRECISION
PRODUCTS

Five Army-Navy "E" awards—the Flag and Four Stars—each of which symbolizes six months of Exacting Service to our Armed Forces, have been awarded to Pollak.

Weighted index based on steel bars, beams, tank plates, wire, rails, black pipe, hot and cold-rolled sheets and strip, representing 78 per cent of the United States output. Index recapitulated in Aug. 28, 1941, issue.

Based on averages for basic iron at Valley furnaces and foundry iron at Chicago, Philadelphia, Buffalo, Valley and Southern iron at Cincinnati.

Based on No. 1 heavy melting steel scrap quotations to consumers at Pittsburgh, Philadelphia and Chicago.

. . . Prices of Finished Iron and Steel

Steel prices shown here are f.o.b. basing points, in cents per lb., unless otherwise indicated. Extras apply. Delivered prices do not reflect 3% tax on freight. (1) Mill run sheet, 10c. per 100 lb. under base; primes 25c. above base. (2) Unassorted 8-lb. coating. (3) Widths up to 12-in. (4) 0.25 carbon and less. (5) Applies to certain width and length limitations. (6) For merchant trade. (7) For straight length material only from producer to consumer. Discount of 25c. per 100 lb. to fabricators. (8) Also shafting. For quantities of 20,000 to 29,999 lb. (9) Carload lot in manufacturing trade. (10) Prices do not apply if rail and water is used. (12) Boxed. (13) Portland and Seattle price, San Francisco 2.50c. (14) This base price to be used in figuring annealed, bright finish wires, commercial spring wire.

EXCEPTIONS TO PRICE SCHED. NO. 6

Slabs—Andrews Steel Co. $41 basing pts.; Wheeling Steel Corp. $34 Portsmouth, Ohio; Empire Sheet & Tin Plate Corp. $41; Phoenix Iron Co. (rerolling) $41, (forging) $47; Granite City Steel Co. $47.50.

Blooms—Phoenix Iron Co. (rerolling) $41, (forging) $47.

Sheet Bar—Empire Sheet & Tin Plate Co. $39 mill; Wheeling Steel Corp. $38 Portsmouth, Ohio.

Billets, Forging—Andrews Steel Co. $50 basing pts.; Follansbee Steel Corp. $49.50 Toronto; Phoenix Iron Co. $47.00 mill.

Billets, Rerolling—Continental Steel Corp. may charge Acme Steel in Chicago switching area $34 plus freight from Kokomo, Ind.; Northwestern Steel & Wire Co. (Lend-Lease) $41 mill; Wheeling Steel Corp. (small) $36 Portsmouth, Ohio; (blooming mill sizes) applicable base, f.o.b. Portsmouth, Ohio; Stanley Works may sell Washburn Wire Co. under allocation at $39 Bridgeport, Conn.; Keystone Steel & Wire Co. may sell Acme Steel Co. at Chicago base, f.o.b. Peoria; Phoenix Iron Co. $41 mill; Continental Steel Corp. (1¾ x 1¾) $39.50, (2 x 2) $40.60 Kokomo, Ind. (these prices include $1 size extra); Keystone Steel & Wire Co. $36.40 Peoria; Connors Steel Co. $50.69 Birmingham; Ford Motor Co. $34 Dearborn, Mich.

Structural Shapes—Phoenix Iron Co. $2.35 basing pts., (export) $2.50 Phoenixville; Knoxville Iron Co. $2.30 basing pts.

Bar Size Shapes—(Angles) W. Ames & Co., 10 tons or over, $3.10 mill.

Rails—Sweet Steel Co. (rail steel) $50 mill; West Virginia Rail Co. (lightweight) on allocation based Huntington, W. Va.; Colorado Fuel & Iron Corp. $45 Pueblo.

Hot Rolled Plate—Granite City Steel Co. $2.65 mill; Knoxville Iron Co. $2.25 basing pts.; Kaiser Co. $3.20 Pacific Ports.

Merchant Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Eckels-Nye Steel Corp., $2.50 basing pts. (rail steel) $2.40; Phoenix Iron Co. $2.40 basing pts.; Sweet Steel Co. (rail steel) $2.35 mill; Joslyn Mfg. & Supply Co. $2.35 Chicago; Central Iron & Steel Co. $2.20 basing pts.; Granite City Steel Co. $2.35 Granite City; Calumet Steel Div., Borg Warner Corp. (8 in. mill bars) $2.35 Chicago; Knoxville Iron Co. $2.30 basing pts. Laclede Steel Co., sales to LaSalle Steel granted Chicago base, f.o.b. Madison, Ill.

Reinforcing Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Sweet Steel Co. (rail steel) $2.35 mill; Columbia Steel Co. $2.50 Pacific Ports.

Cold Finished Bars—Keystone Drawn Steel Co. on allocation, Pittsburgh c.f. base plus c/l freight on hot rolled bars Pittsburgh to Spring City, Pa.; New England Drawn Steel Co. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to Massfield, Mass., f.o.b. Massfield.; Empire Finished Steel Corp. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to plants f.o.b. plant; Compressed Steel Shafting Co. on allocation outside New England, Buffalo base plus c/l freight Buffalo to Readville, Mass. f.o.b. Readville; Medart Co. in certain areas, Chicago c.f. base plus c/l freight Chicago to St. Louis, f.o.b. St. Louis.

Alloy Bars—Texas Steel Co. for delivery except Texas and Okla. Chicago base, f.o.b. Fort Worth, Tex.; Connors Steel Co. shipped outside Ala., Mississippi, Louisiana, Georgia, Florida, Tenn., Pittsburgh base, f.o.b. Birmingham.

Hot Rolled Strip—Joslyn Mfg. & Supply Co. $2.30 Chicago; Knoxville Iron Co. $2.25 basing pts.

Hot Rolled Sheets—Andrews Steel Co., Middletown base on shipments to Detroit or area; Parkersburg Iron & Steel Co., $2.25 Parkersburg.

Galvanized Sheets—Andrews Steel Co., $3.75 basing pts.; Parkersburg Iron & Steel Co. $3.85 Parkersburg; Apollo Steel Co. $3.75 basing pts.; Continental Steel Co., Middletown base on Kokomo, Ind., product; Superior Sheet Steel Co., Pittsburgh base except for Lend-Lease.

Pipe and Tubing—South Chester Tube Co. when priced at Pittsburgh, freight to Gulf Coast and Pacific Ports may be charged from Chester, Pa., also to points lying west of Harrisburg, Pa.

Black Sheets—Empire Sheet and Tinplate Co., maximum base price mill is $2.45 per 100 lb., with differentials, transportation charges, etc., provided in RPS. No. 6.

WAREHOUSE PRICES

Delivered metropolitan areas per 100 lb. These are zoned warehouse prices in conformance with latest zoning amendments to OPA Price Schedule 49.

*Recommended for large sections only. Note: The extras shown are in addition to a base price of 2.70c. per 100 lb., on finished products and $54 per gross ton on semi-finished steel major basing points and are in cents per 100 lb. and dollars per gross ton in semi-finished. When acid open-hearth is specified and acceptable add to basic open hearth alloy differential 0.25c. per lb. for bars and bar strip, $5.00 per gross ton for billets, blooms and slabs. The ranges shown above are restricted to sizes 100 sq. in. or less or equivalent cross sectional area 18 in. wide or under with a max. individual piece weight of 7000 lb.

BASE QUANTITIES

Standard unless otherwise keyed on prices.

HOT ROLLED: Sheets, strip, plates, shapes and bars, 400 to 1999 lb.

COLD ROLLED: Sheets, 400 to 1499 lb.; strip, extras on all quantities; bars, 1500 lb. base; NE alloy bars, 1000 to 39,999 lb.

EXCEPTIONS: (1) 150 to 499 lb. (2) 150 to 1499 lb. (3) 400 to 1499 lb. (4) 450 to 1499 lb. (5) 500 to 1499 lb. (6) 0 to 1999 lb. (7) 400 to 1999 lb. (8) 1000 to 1999 lb. (9) 450 to 3749 lb. (10) 400 to 3999 lb. (11) 300 to 4999 lb. (12) 300 to 10,000 lb. (13) 400 to 14,999 lb. (14) 400 lb. and over. (15) 1000 lb. and over. (16) 1500 lb. and over. (17) 2000 lb. and over. (18) 3500 lb. and over.

(a) Philadelphia: Galvanized sheets, 25 or more bundles.

Extra for size, quality, etc., apply on above quotations.

*Add 0.271c. for sizes not rolled in Birmingham.

**City of Philadelphia only. Applicable freight rates must be added to basing point prices to obtain delivered price to other localities in metropolitan area.

LAKE SUPERIOR ORES

(51.50% *Fe, Natural Content, Delivered Lower Lake Ports)**

	Per Gross Ton
Old range, bessemer, 51.50	$4.75
Old range, non-bessemer, 51.50	4.60
Mesaba, bessemer, 51.50	4.60
Mesaba, non-bessemer, 51.50	4.45
High phosphorus, 51.50	4.35

*Adjustments are made to indicate prices based on variance of Fe content of ores as analyzed on a dry basis by independent laboratories.

FLUORSPAR

Maximum price f.o.b. consumer's plant, $30 per short ton plus either (1) rail freight from producer to consumer, or (2) rail freight from Rosiclare, Ill., to consumer, whichever is lower.

Exception

When the WPB Steel Division certifies in writing the consumer's need for one of the higher grades of metallurgical fluorspar specified in the table below the price shall be taken from the table plus items (1 and 2) from paragraph above.

Effective CaF_2 Content:	*Base price per short ton*
70% or more	$33.00
65% but less than 70%	32.00
60% but less than 65%	31.00
Less than 60%	30.00

SEMI-FINISHED STEEL

Ingots, Carbon, Rerolling

Base per gross ton, f.o.b. mill.... $31.00
Exceptions: Phoenix Iron Co. may charge $38.75; Kaiser Co., $43.00 f.o.b. Pacific Coast Ports; Empire Sheet & Tinplate Co., $34.25.

Ingots, Carbon, Forging

Base per gross ton, f.o.b. Birmingham, Buffalo, Chicago, Cleveland, Gary, Pittsburgh, Youngstown $36.00
Exceptions: Phoenix Iron Co. may charge $43.00; Empire Sheet & Tinplate Co., $39.25, f.o.b. Mansfield, Ohio; West Coast producers, $48.00, f.o.b. Pacific Coast Ports.

Ingots, Alloy

Base per gross ton, f.o.b. Bethlehem, Buffalo, Canton, Coatesville, Chicago, Massillon, Pittsburgh $45.00
Exceptions: C/L delivered Detroit add $2.00; delivered East Michigan add $3.00. Connors Steel Co. may charge $45.00 f.o.b. Birmingham.

Billets, Blooms and Slabs

Pittsburgh, Chicago, Gary, Cleveland, Youngstown, Buffalo, Birmingham, Sparrows Point (rerolling only). Prices delivered Detroit are $2.00 higher; delivered E. Michigan, $3 higher; f.o.b. Duluth, billets only, $2.00 higher; billets f.o.b. Pacific ports are $12 higher. Delivered prices do not reflect three per cent tax on freight rates.

	Per Gross Ton
Rerolling	$34.00
Forging quality	40.00

For exceptions on semi-finished steel see the footnote on the page of finished steel prices.

Alloy Billets, Blooms, Slabs

Pittsburgh, Chicago, Canton, Massillon, Buffalo, or Bethlehem, per gross ton 54.00
Price delivered Detroit $2.00 higher; E. Michigan $3.00 higher.

Shell Steel

	Per Gross Ton
3 in. to 12 in.	$52.00
12 in. to 18 in.	54.00
18 in. and over	56.00

Basic open hearth shell steel, f.o.b. Pittsburgh, Chicago, Buffalo, Gary, Cleveland, Youngstown and Birmingham.
Prices delivered Detroit are $2.00 higher; E. Michigan, $3 higher.
Note: The above base prices apply on lots of 1000 tons of a size and section to which are to be added extras for chemical requirements, cutting, or quantity.

Sheet Bars

Pittsburgh, Chicago, Cleveland, Youngstown, Buffalo, Canton, Sparrows Point.

	Per Gross Ton
Open hearth or bessemer	$34.00

Skelp

Pittsburgh, Chicago, Youngstown, Coatesville, Pa., Sparrows Point, Md.

	Per Lb
Grooved, universal and sheared	1.90c

Wire Rods

(*No. 5 to 9/32 in.*)

	Per Lb
Pittsburgh, Chicago, Cleveland	2.00c
Worcester, Mass.	2.10c
Birmingham	2.00c
San Francisco	2.50c
Galveston	2.25c

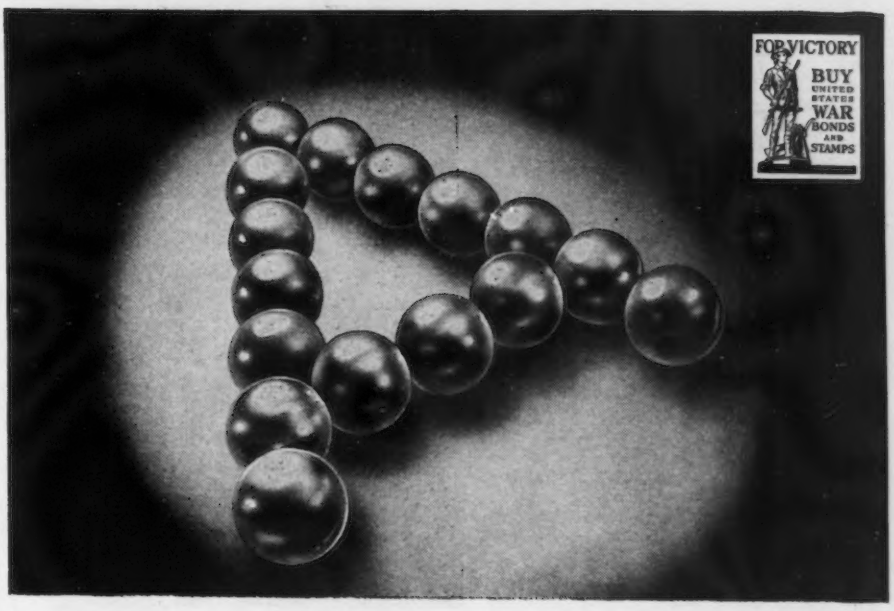
9/32 in. to 47/64 in., 0.15c. a lb. higher. Quantity extras apply.

TOOL STEEL

(*F.o.b. Pittsburgh, Bethlehem, Syracuse*)

	Base per lb
High speed	67c.
Straight molybdenum	54c.
Tungsten-molybdenum	57½c.
High-carbon-chromium	43c.
Oil hardening	24c.
Special carbon	22c.
Extra carbon	18c.
Regular carbon	14c.

Warehouse prices east of Mississippi are 2c. a lb. higher; west of Mississippi 1c. higher.



CARRY THE LOAD AS PLANNED

ROLL ON ABBOTT Bearing BALLS

GET UNINTERRUPTED PERFORMANCE

Production schedules are met—contracts are fulfilled — UNINTERRUPTED PERFORMANCE is achieved from each piece of equipment—each mechanism . . . Users are proving daily that time and labor are saved because their BEARING BALL assemblies are "ABBOTT" . . . ABBOTT has the answers to BEARING BALL problems. Your "tough performance job" may be a "regular" for ABBOTT. Get the vital UNINTERRUPTED PERFORMANCE by specifying "ABBOTT"—carry the load as planned.

ASK FOR DELIVERY ESTIMATES ON THE GRADE OF BALL TO MATCH YOUR STANDARDS OF PRECISION.

SPECIFY "ABBOTT"

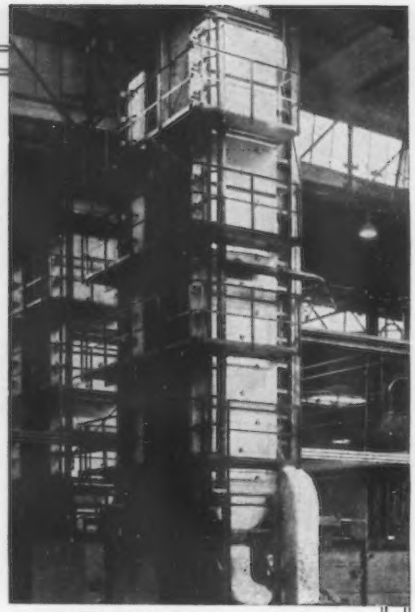
ROLL ON ABBOTT Bearing BALLS
THE ABBOTT BALL COMPANY HARTFORD, CONN. U.S.A.

Big Installations
or Small Parts--

Call BRANDT of Baltimore

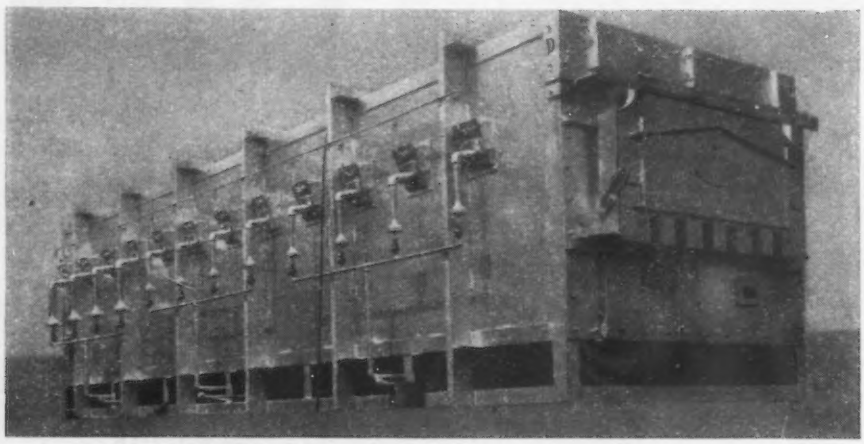
for precision in Heavy Plate and Sheet Steel Work

Here is an 8½ acre plant . . . with the most modern equipment for shearing, rolling, forming, welding and completely fabricating ferrous, non-ferrous and alloy metals to your specifications . . . from the lightest gauge up to and including 1¼" mild steel or ¾" armor plate. Extensive war contracts necessarily limit our present acceptance of new business for immediate delivery. Address: Charles T. Brandt, Inc., Baltimore-30, Md.



BRIGHTENING FURNACE, 44 ft. high, for use with Continuous Electrolytic Tinning Lines . . . Furnaces and Tinning Lines engineered, fabricated and installed by Brandt.

BRANDT of Baltimore—*Craftsmen in Metal Since 1890*



BELLEVUE FURNACES

are designed for the job.

In the construction of Bellevue Furnaces, painstaking consideration of the job to be done comes first. Every factor must be evaluated, every condition studied. Only then do Bellevue engineers attempt design and recommendation of furnace type.

The soundness of that policy is being demonstrated in plant after plant. Hundreds of executives in scores of varied companies have proved, to their own satisfaction, the efficiency, speed, high production level and operating economies of Bellevues that were "designed" for the job.

You, too, will find Bellevue experience and facilities a profitable investment for your own furnace needs.

Send for full details.

BELLEVUE INDUSTRIAL FURNACE CO.
2974 BELLEVUE AVENUE DETROIT, MICH.

WELDED PIPE AND TUBING

Base Discounts, f.o.b. Pittsburgh District and Lorain, Ohio, Mills

(F.o.b. Pittsburgh only on wrought pipe)
Base Price—$200 per Net Ton

	Black	Galv.
Steel (Butt Weld)		
½ in.	63½	51
¾ in.	66½	55
1 to 3 in.	68½	57½
Wrought Iron (Butt Weld)		
½ in.	24	3½
¾ in.	30	10
1 and 1¼ in.	34	16
1½ in.	38	18½
2 in.	37½	18
Steel (Lap Weld)		
2 in.	61	49½
2½ and 3 in.	64	52½
3½ to 6 in.	66	54½
Wrought Iron (Lap Weld)		
2 in.	30½	12
2½ to 3½ in.	31½	14½
4 in.	33½	18
4½ to 8 in.	32½	17
Steel (Butt, extra strong, plain ends)

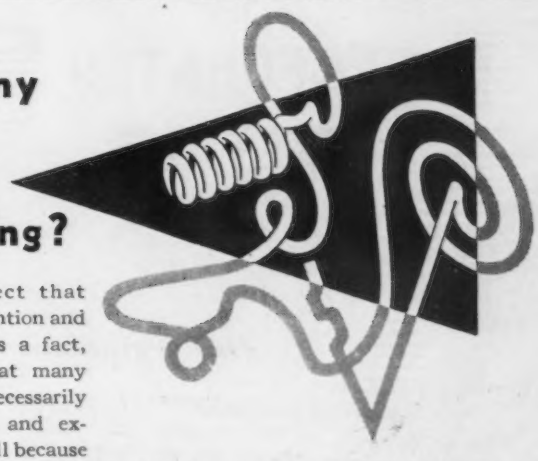
How many BENDS in a Spring?



Here's a subject that deserves close attention and investigation. It's a fact, sad but true, that many springs are unnecessarily intricate, difficult and expensive to make, all because of lack of understanding of the ultimate purpose. Ofttimes, a simplified design—or a different type of material can do wonders in the way of reducing costs and "upping" performance. Here's where experience in spring design pays off. Let the springmaker in on your requirements—in the early stages if possible.

A good spring in time saves nine!

GRAY FORGE IRON: Valley or Pittsburgh furnace $23.50

(1) Pittsburgh Coke & Iron Co. (Sharpsville, Pa., furnace only) and the Struthers Iron and Steel Co., Struthers, Ohio, may charge 50c. a ton in excess of basing point prices for No. 2 foundry, basic, bessemer and malleable. Struthers Iron and Steel Co. may add another $1.00 per gross ton for iron from Struthers, Ohio, plant.

(2) Price shown is for low-phosphorous iron; high phosphorous sells for $28.50 at the furnace.

(3) E. & G. Brooke Co. Birdsboro, Pa., permitted to charge $1.00 per ton extra.

(4) Pittsburgh Ferromanganese Co. (Chester furnace only) may charge $2.25 a ton over maximum basing point prices.

Basing point prices are subject to switching charges; Silicon differentials (not to exceed 50c. a ton for each 0.25 per cent silicon content in excess of base grade which is 1.75 to 2.25 per cent); Phosphorus differentials, a reduction of 38c. per ton for phosphorus content of 0.70 per cent and over; Manganese differentials, a charge not to exceed 50c. per ton for each 0.50 per cent manganese content in excess of 1.00 per cent. Effective March 3, 1943, $2 per ton extra may be charged for 0.5 to 0.75 per cent nickel content and $1 per ton extra for each additional 0.25 per cent nickel.

METAL POWDERS

Prices are based on current market prices of ingots plus a fixed figure. F.o.b. shipping point, c. per lb., ton lots.

Copper, electrolytic, 150 and 200 mesh	21⅛ to 23½c.
Copper, reduced, 150 and 200 mesh	20½ to 25½c.
Iron, commercial, 100 and 200 mesh, 96 + % Fe	13½ to 15c.
Iron, crushed, 200 mesh and finer, 90 + % Fe	4c.
Iron, hydrogen reduced, 300 mesh and finer, 98½ + % Fe	63c.
Iron, electrolytic, unannealed, 300 mesh and coarser, 99 + % Fe	30 to 33c.
Iron, electrolytic, annealed minus 100 mesh, 99 + % Fe	42c.
Iron, carbonyl, 300 mesh and finer, 98-99.8 + % Fe	90c.
Aluminum, 100 and 200 mesh	*23 to 27c.
Antimony, 100 mesh	20.6c.
Cadmium, 100 mesh	$1
Chromium, 150 mesh	$1.03
Lead, 100, 200 & 300 mesh,	11½ to 12½c.
Manganese, 150 mesh	51c.
Nickel, 150 mesh	51½c.
Solder powder, 100 mesh, 8½c. plus metal	
Tin, 100 mesh	58¾c.
Tungsten metal powder, 98%-99%, any quantity, per lb.	$2.60
Molybdenum power, 99%, in 200-lb. kegs, f.o.b. York, Pa., per lb.	$2.60
Under 100 lb.	$3.00

*Freight allowed east of Mississippi.

IF THERE IS A FLAW "FLASH-O-LENS" WILL FIND IT!

The new FLASH-O-LENS offers foundry-men, machinists, and many others engaged in producing metal parts for war contracts an efficient, economical means of examining the most minute defects during routine inspections.

FLASH-O-LENS consists of a portable 40x microscope combined with a perfect source of illumination in one convenient, compact unit . . . They are available in several models—powered by either standard flash light dry cells or by current from any AC or DC outlet—and with a selection of various combinations of lenses, all interchangeable in the one lens housing.

Send today for illustrated catalog describing the new FLASH-O-LENS

Manufacturers — ELIZABETH, N. J.

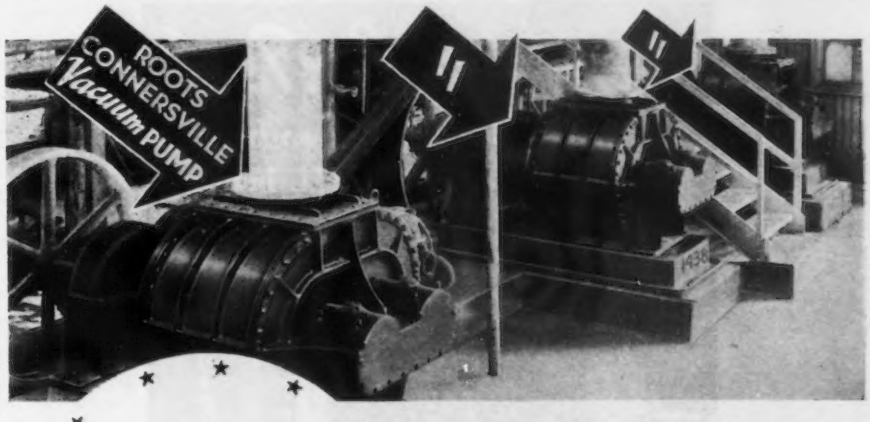

Photo shows three heavy duty "R-C" Vacuum Pumps, installed in a New Mexico plant. Capacity 4,250 c.f.m. each; suction 10" mercury.

Write for Bulletin.

"R-C" Positive Displacement Vacuum Pumps will handle more air per horsepower, under moderate vacuums, than any other type of pump.

They are extensively used for filter service, dewatering of sludges and pulps, testing purposes, pneumatic conveying, priming centrifugal pumps, and other applications where a dependable, economical, and steady vacuum is required.

Did you Know?

Over 50% of furnace wall radiation losses alone can be stopped? Therm-O-Flake Insulation is preferred for this work in most steel plants.

Here's why!

Highest insulating value — easy to apply — low maintenance — low cost — high reclamation — sticks tightly to silica or basic brick — permits closer control of fuel-air ratios — reduces cold air infiltration.

Bortram, f.o.b. Niagara Falls

Ton lots, per lb.	45c.
Less ton lots, per lb.	50c.

Ferrocolumbium, 50-60%, contract basis, f.o.b. plant with freight allowances, per lb contained Cb.

2000 lb. lots	$2.25
Under 2000 lb. lots	$2.30

Ferrotitanium, 40%-45%, f.o.b. Niagara Falls, N. Y., ton lots, per lb. contained titanium ... $1.23
Less ton lots $1.25

Ferrotitanium, 20%-25%, 0.10 C max., ton lots, per lb. contained titanium $1.35
Less ton lots $1.40

High-carbon ferrotitanium, 15%-20%, 6%-8% carbon, contract basis, f.o.b. Niagara Falls, N. Y., freight allowed East of Mississippi River, North of Baltimore and St. Louis, per carload $142.50

Ferrophosphorus, 18% electric or blast furnace, f.o.b. Anniston, Ala., carlots, with $3 unitage freight equaled with Rockdale, Tenn., per gross ton $58.50

Ferrophosphorus, electrolytic 23-26%, carlots, f.o.b. Monsanto (Siglo), Tenn., $3 unitage freight equalized with Nashville, per gross ton $75.00

Ferromolybdenum, 55-75%, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained molybdenum ..... 95c.

Calcium molybdate, 40%-45%, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained Mo ..... 80c.

Molybdenum oxide briquettes, 48%-52% Mo, f.o.b. Langeloth, Pa., per lb. contained Mo ..... 80c.

Molybdenum oxide, in cans, f.o.b. Langeloth and Washington, Pa., per lb. contained Mo ..... 80c.

Zirconium, 35-40%, contract basis, f.o.b. producer's plant with freight allowances, per lb. of alloy. Add ¼c. for spot sales
Carload lots ..... 14c.

Zirconium, 12-15%, contract basis, lump, f.o.b. plant with usual freight allowances, per lb. of alloy
Carload, bulk ..... 4.6c.

Alsifer (approx. 20% Al, 40% Si and 40% Fe), contract basis, f.o.b. Niagara Falls, carload, bulk ..... 6.5c.
Ton lots ..... 7.25c.

Simanal (approx. 20% Si, 20% Mn, 20% Al), contract basis, f.o.b. Philo, Ohio, with freight not to exceed St. Louis rate allowed, per lb.

Car lots	8.75c.
Ton lots	9.25c.

FOR ALL TYPES of INDUSTRIAL FURNACES

NATIONAL AIROIL FUEL OIL - GAS BURNERS

Movable Flame Billet Heating Oil Burner

In this unit, the burner is arranged on a sliding carriage with a ball and socket adaptor which permits easy and exact placement of the flame to any part of the furnace and withdrawal of the burner from the furnace when not in use. The burner furnished with this unit is the Type SA, illustrated below.

With extension tip for firing heavy fuel oil or tar, using steam or compressed air for atomization. Venturi throat and internal expansion insures fine atomization and low steam or air consumption. Holds steady as a gas flame. Tips for cone, round or flat flame of any angle.

Steam Atomizing Oil Burners—Mechanical Pressure Atomizing Oil Burners—Low Air Pressure Oil Burners—Motor-driven Rotary Oil Burners—Industrial Gas Burners—Combination Gas and Oil Burners—Fuel Oil Pumping Units—Fuel Oil Heaters—Fuel Oil Strainers and other accessories.

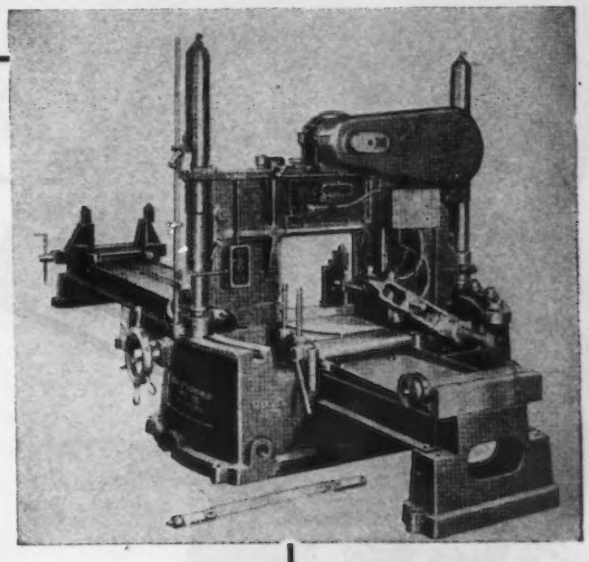
CUTS the Toughest Steels and Largest Sizes *easily.*



This giant hydraulic metal - cutting saw is more than just a larger hack saw. It is a new development in metal-cutting methods that introduces a new principle of metal sawing — the Roll-stroke blade action makes it possible to cut the toughest steels in the largest sizes easily and rapidly. It also permits a simple and efficient, very low pressure Hydraulic Feed System.

Built for heavy work, completely enclosed in heavy housing, this machine will stand up under the rough usage of the average steel mill warehouse and forge shop, where it will speed cutting-off, and reduce material loss.

MARVEL No. 18
Giant Hydraulic Hack Saw
Capacity 18"x18"
Cuts angles up to 45° by simply swiveling upper machine housing.

Farquhar

Production line installations like these show how Farquhar Hydraulic Presses are meeting today's unprecedented industrial demands. They are examples that may well point your way to profitable peacetime operations.

For instance, one of the presses shown here replaced an obsolete process and in so doing saved as high as 28% of virgin metal in addition to turning out better work. A Farquhar Hydraulic Production Press may do the same for you; may save time, labor and bridge over unnecessary steps.

Farquhar Hydraulic Press Engineers know how to apply their equipment to modern production. With

The Silent Doers

SOMETIMES one observes what is and sometimes he may observe even more forcibly what isn't. Like the man who, seeing the prairies for the first time, asked: "Where are the mountains?"

Anyone who has had sufficient contact with industry must have observed that the doers are usually men of few words. The engineers, production men, foremen, superintendents and active managers are in the category of "the strong and silent" who do not talk much.

Not that they cannot talk, and eloquently, when they see fit. But to see fit they first must know that you are genuinely interested in what they are doing, and second that you are capable of understanding it. Otherwise they feel that their time can be better spent.

Shop talk is as a rule confined to the fewest and shortest words necessary to convey an idea clearly. It is concise, which means that it expresses much in few words. That this is an asset and not a liability is proved by the fact that it gets things done. Verbosity either in speech or writing leads to confusion of thought or conceals a lack of it. It was said of Charles E. Sorensen, the noted Ford production executive, that if you wanted him to read a letter or a statement you had best get it all on one page.

What a blessing it would be if our statesmen and administrative officials would adopt this principle of brevity plus clarity. Not only would it save the time required to turn out and to read billions of unnecessary words and thus automatically solve the paper shortage, but one would know what they meant and also whether they were merely concealing a crooked needle of thought in a verbal haystack.

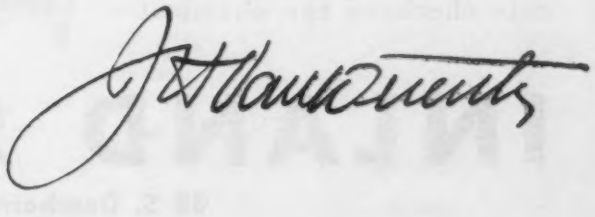
The Baruch report, like some others written by doers called to Washington, is a fine example of clarity and brevity. But it is a report only and God alone knows what will happen to its understandability after the legalistic phrase makers get through with it.

When you are hiring a doer in industry you are looking for a smooth thinker. If the applicant for the job is glib or garrulous, he has two strikes on him to start with.

One reason why we and the rest of the world are in such a mess is that we select our elected officials on the basis of word tonnage rather than performance poundage. George Romney of the Automobile Manufacturers' Association has well expressed this as follows:

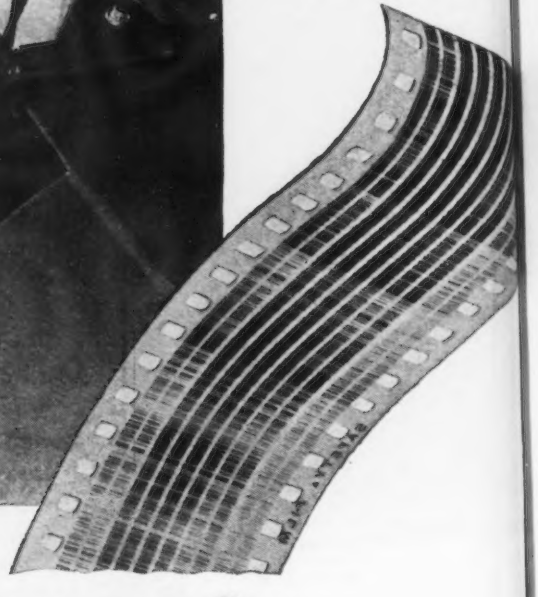
"There is one peculiarity about the past decade that is startlingly obvious. This is the curious fact that for about ten years in virtually all of the so-called civilized countries, the management of human affairs gravitated strongly into the hands of leaders who could talk glibly, write elegantly and argue forcibly but who were notoriously deficient in the ability to act competently."

After that, perhaps the less said the better.



Examination of the spectrum emanating from the vaporization of the steel sample in an electric arc quickly reveals the chemical content of the sample.

A spectrographic film provides a permanent record of each sample.



How the Spectrograph Helps Maintain Inland Quality

Every open hearth heat run at the Inland mills is checked not only by routine control methods of chemical analysis, but also in a special spectrographic laboratory.

Inland was one of the first steel mills in America to install and develop technique for using the spectrograph in control of quality. An important advantage of this method is the rapidity with which tests can be made. At any stage during the working of a heat a melter can have an accurate check on the chemical content within ten minutes after a sample is delivered to the laboratory. Not only do these frequent and rapid tests assure the uniform high quality of Inland steel, but they also help maintain capacity production—a vital necessity in this time of war.

The spectrographic analysis is only one of the many checks and balances used by Inland in the production of steel—it is only one of the numerous quality control methods adopted by Inland after rigid tests prove their practicability.

The IRON AGE
MARCH 23, 1944

NEWS FRONT

► The Steel Division of WPB, which at one time had 800 employees, now has less than 450.

► At Wright Field, an expanded program for disposal of surplus aircraft material is taking shape. The program, formulated by Lt. Col. A. E. R. Peterka, contemplates distribution of surplus materials by gathering them at centralized depots from which they will be filtered out through industry-operated warehouses or directly from contractors' plants to the warehouse distributors.

► Reductions in magnesium production at five plants have been ordered by WPB. The reduction will amount to about 33,750,000 lb. annually or less than 6 per cent of national capacity.

► The Truman Committee expects total employment to reach 53,400,000 by July with unemployment remaining at approximately the present level of one million.

The committee has taken a stand against the argument that reducing the civilian economy to bare levels of subsistence will bolster the morale of the men in the armed services.

They argue that a sound healthy economy must be maintained to wage a long war and provide jobs for the returning fighters.

► The much-juggled 1944 truck program has been shaken down more than 15 per cent in the Army vehicle category. Of the 742,433 military units originally planned for production this year, 123,149 have been eliminated, including 42,013 medium and 81,136 light trucks.

More facts on cutbacks are coming to light. Jeep production has been severely reduced, and the entire half-track program has been all but eliminated.

► Authorization has come from WPB for completion of the structural steel mill at the Geneva plant. When completed, the 26-in. mill will have an annual capacity of 200,000 net tons of structural shapes, billets and rounds.

Rail rates are now being studied since the entire economy and future of Geneva operations depend almost entirely on what the rail rate to Coast points will be.

► Rumors are being circulated that ship construction after June, 1944, will be curtailed drastically.

► Additional experimental evidence on the effects of sub-zero cooling on the tempering of high speed steel indicates that this practice will within the next few years become a routine commercial practice.

The maximum secondary hardness is attained in the sub-zero treated specimens at a lower temperature--and in a shorter time--than that for specimens in which the cooling was stopped at room temperature.

Indications are that sub-zero treatment following the first tempering operation will eliminate the need of a third tempering operation to secure a completely tempered martensitic structure.

► A survey of commercial installations of submerged heating of pickling solutions indicates that they may well result in considerable saving in time, acid and equipment. Better pickling department working conditions also result.

► The Progressive Welder Co. is now marketing a practical d.c. resistance welder using storage batteries as a source of welding current.

► By setting up an ideal gear with no error, a method has been developed to present a general classification of spur gear errors and a method of recording and evaluating the deviations.

► According to the Algiers radio consideration is being given to the use of helicopters in evacuating wounded men from the high mountain positions in Italy. At most only two wounded could be carried at one time.

► One of the smarter London dailies has discovered a new German secret weapon. Newly invented aircraft loudspeakers will pour an incessant flood of sound on England, destroying the nerves of the population. No mention is made of what the aircraft crews will use to save their own nerves. Probably an ear plug--i.e., a round peg in a square head.

. . . Some Effects of Sub-Zero C

By G. A. ROBERTS
Research Metallurgist,
and
J. P. GILL
Vice-President and Chief Metallurgist, Vanadium-Alloys Steel Co., Latrobe, Pa.

o o o

INTEREST in the application of sub-atmospheric temperatures to the heat treatment of metals has recently reached a new high. This is especially true for the heat treatment of high speed steel. At the present time it is too early to present detailed, accurate and complete information concerning the increase in cutting tool performance obtained when high speed steel is subjected to treatments involving the use of sub-zero temperatures. Suffice it to say that favorable reports have been made and that without doubt a further and continued investigation of the merits of this process is warranted.

Rather meager knowledge of the effects and benefits of such treatments on high speed steel has been obtained within the past several years, although it must be admitted that metallurgists have been aware of the possibility of transforming retained austenite to martensite by the use of sub-zero temperatures for several decades.

In 1937 Gulyaev[1] reported that the sub-zero treatment of high speed steel permits higher cutting speeds when working with short chips. Two year later this same author[2] investigated the kinetics of the sub-atmospheric austenite transformation in high speed steel by making magnetic measurements during cooling to —297 deg. F. He showed that, after hardening at the usual temperatures, the austenite transformation range extends well below room temperature but that complete transformation of the austenite is not attained by such sub-zero cooling. He also found that room temperature aging of hardened high speed steel stabilizes the retained austenite so that the sub-atmospheric transformation is partially suppressed.

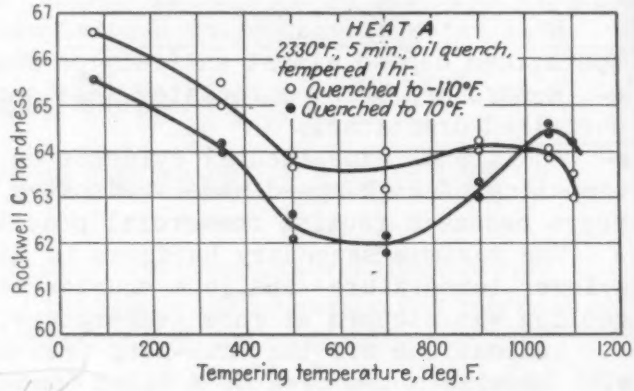
RIGHT

FIG. 2 — Effect of sub-zero hardening on the tempering of high speed steel at temperatures between 80 deg. F. and 1200 deg. F.



o o o

The first comprehensive American paper to be published on this subject appeared in 1942[3].

In it the authors, Gordon and Cohen, verified the findings of Gulyaev by means of hardness, dilatometric, magnetic and specific volume measurements. In addition, these authors showed that the sub-zero cooling not only provides, in certain instances, an increase in hardness and strength but also results in a remarkable increase in ductility. These results are summarized in Table V of their paper which is reproduced as Table I herein.

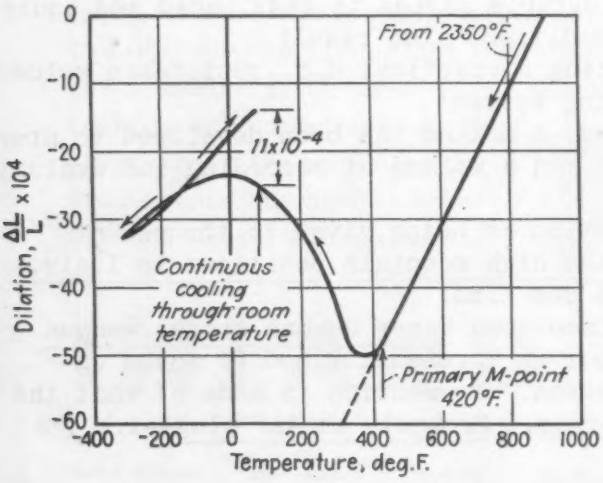
[3] *M. P. Gordon and M. Cohen, "Transformation of Retained Austenite in High Speed Steel at Sub-Atmospheric Temperatures," Transactions A.S.M., Vol. 30, 1942, p. 569.*

A brief review of the fundamental principles of hardening high speed steel is warranted to permit a more thorough understanding of the phenomena occurring during sub-zero treatments. At the hardening temperature, high speed steel (of any type) consists of a mixture of highly alloyed austenite and undissolved complex carbide. The latter occupies from 5 to 10 per cent of the volume of the steel. On oil quenching (or even air cooling) the austenite is stable until the M-point is reached. The dilatometric curve for the cooling of an 18-4-1 type high speed steel from 2350 deg. F. to sub-zero temperatures (Fig. 1) illustrates this state of affairs. On cooling below the M-point the austenite continuously

o o o

LEFT

FIG. 1—Dilatometric curve of an 18-4-1 high speed steel cooled from 2350 deg. F. to —310 deg. F. showing the M-point and the continuous nature of the austenite-martensite reaction on cooling to below room temperature. After Gordon and Cohen[3].



o o o

Cooling on the Tempering of High Speed Steel

. . . Great attention is now being given to the application of sub-atmospheric treatment of metals, particularly high speed steel. The authors herein review past work and give data on recent experiments indicating that this treatment has very important commercial applications that will become quite prominent within the next several years.

decomposes into martensite. It is to be particularly noted that this decomposition exhibits no discontinuity at room temperature but proceeds until a temperature of —150 deg. F. is reached.

It is generally agreed that approximately 20 per cent austenite remains at room temperature. When cooled directly to temperatures of —310 deg. F., 60 per cent of this austenite, retained at room temperature, transforms to martensite. The major portion of this additional transformation occurs on cooling to temperatures of —110 deg. F. and thus it can be assumed that after cooling to this latter temperature the retained austenite in high speed steel amounts to only 8 or 10 per cent by volume. The M_c—and M_{90}—points* for high speed steel of this type, austenitized at 2350 deg. F., are therefore, 420 deg. F. and —110 deg. F. respectively.

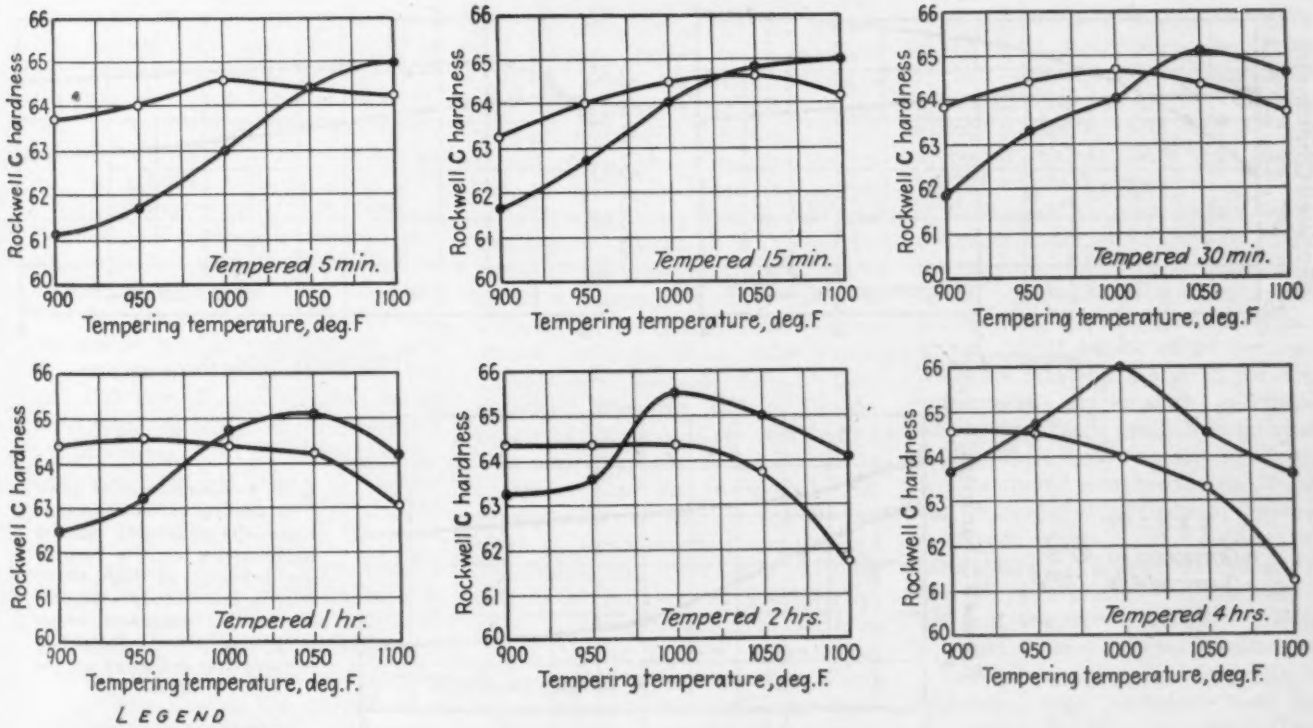
If the austenite is permitted to remain at room temperature for even short periods of time it is partially stabilized. However, on further cooling at least 30 per cent of the austenite retained at room temperature will transform to martensite resulting in a retained austenite content of 14 to 15 per cent at —110 deg. F. If, on the other hand, the cooling is stopped before room temperature is reached, there will be considerable quantities of retained austenite when the steel is heated for tempering. It is estimated that at a temperature of 275 deg. F. approximately 65 per cent austenite remains untransformed.

The data recorded below are the results of recent experiments which were undertaken as a part of the comprehensive program to enable a better understanding of the practical aspects of sub-zero hardening of high speed steel. The analyses of the two

o o o

The use of the numeral subscripts in this sense to indicate the amount of martensite in per cent which exists at any temperature is perhaps more satisfactory than the use of other methods since it permits a quantitative representation of the whole course of the austenite-martensite reaction in a simplified manner.

FIG. 3—Comparison of effect of cooling to room temperature with cooling to sub-zero temperatures on the tempering behavior of high speed steel in the secondary hardening range. Hardness versus tempering temperature. Tempering times indicated on the curves.



high speed steels used in this investigation follow:

Heat A

	Per Cent
Carbon	0.70
Silicon	0.28
Manganese	0.21
Sulphur	0.010
Phosphorus	0.017
Tungsten	17.70
Chromium	4.01
Vanadium	1.01

Size: 3/8 in. sq. x 3 in.

Heat B

	Per Cent
Carbon	0.74
Silicon	0.33
Manganes	0.21
Sulphur	0.013
Phosphorus	0.019
Tungsten	17.68
Chromium	4.05
Vanadium	1.03

Size: 5/16 in. sq. x 2 1/2 in.

The specimens were preheated at a temperature of 1450 deg. F. in a salt bath, then transferred to a high temperature salt bath maintained at 2330 deg. F. In all cases the austenitizing time, not including the time required for heating to the bath temperature, was 5 min. The specimens were oil quenched to a temperature of approximately 800 deg. F. and then air cooled to room temperature. The samples subjected to the sub-zero treatment were immediately placed in a mixture of dry ice and alcohol maintained at a temperature of —110 deg. F. and left in this bath for a period of 2 hr. Tempering was conducted in a salt bath at the temperature and for the times indicated in the tables and illustrations.

The sub-zero temperatures used in these experiments were obtained in a simple metal chamber, 12 in. in diameter by 20 in. high, insulated on all sides with 12 to 15 in. of sawdust. The alcohol used was a commercial grade. Maintenance of a temperature of —110 deg. F., measured with either a copper-constantan thermocouple or with a low temperature thermometer, for periods of 6 to 8 hr. was possible with approximately 15 lb. of dry ice in 4 to 5 gal. of liquid. The consumption of dry ice, of course, increases as the amount of metal to be treated increases.

In all cases the hardness of the specimens as quenched to room temperature but without benefit of the sub-zero treatment ranged between 64.7 and 65.5 Rockwell C before tempering. On the other hand, the hardness of specimens which were subjected to the dry ice treatment ranged between 65.7 and 66.3 Rockwell C before tempering.

In order to compare the effects of sub-zero hardening upon the complete tempering curve for high speed steel Fig. 2 is included. It will be noted that the sub-zero hardened specimens are superior in hardness after a 1 hr. tempering treatment until a temperature of approximately 1000 deg. F. is reached.

The cooling high speed steel con-

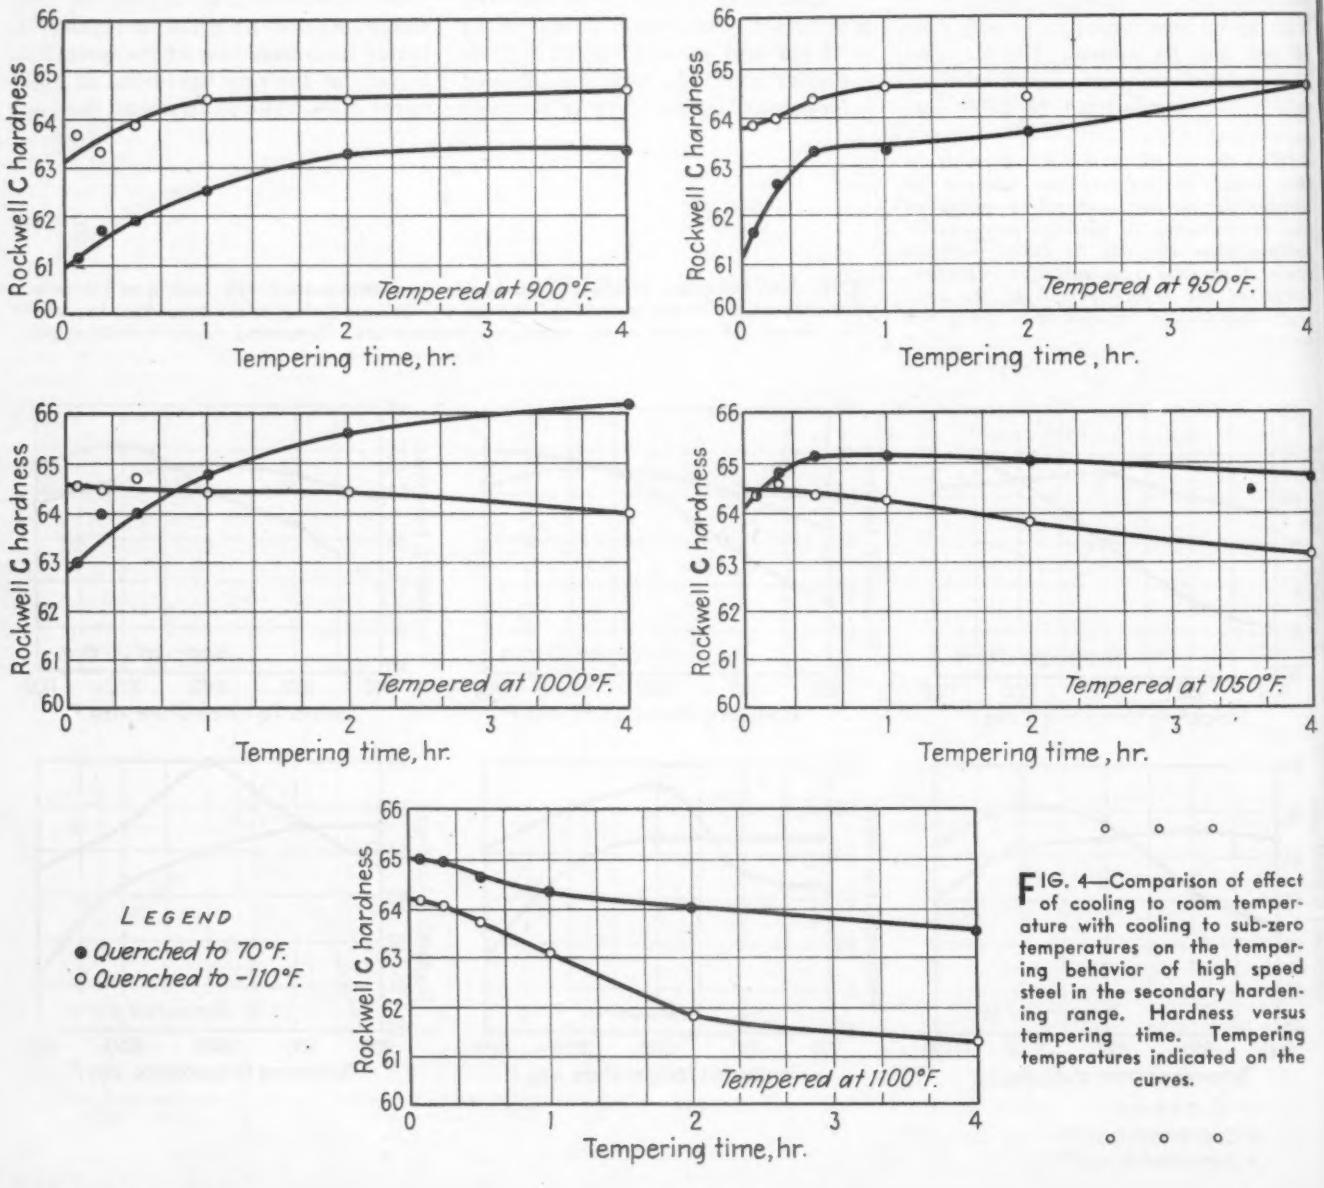


FIG. 4—Comparison of effect of cooling to room temperature with cooling to sub-zero temperatures on the tempering behavior of high speed steel in the secondary hardening range. Hardness versus tempering time. Tempering temperatures indicated on the curves.

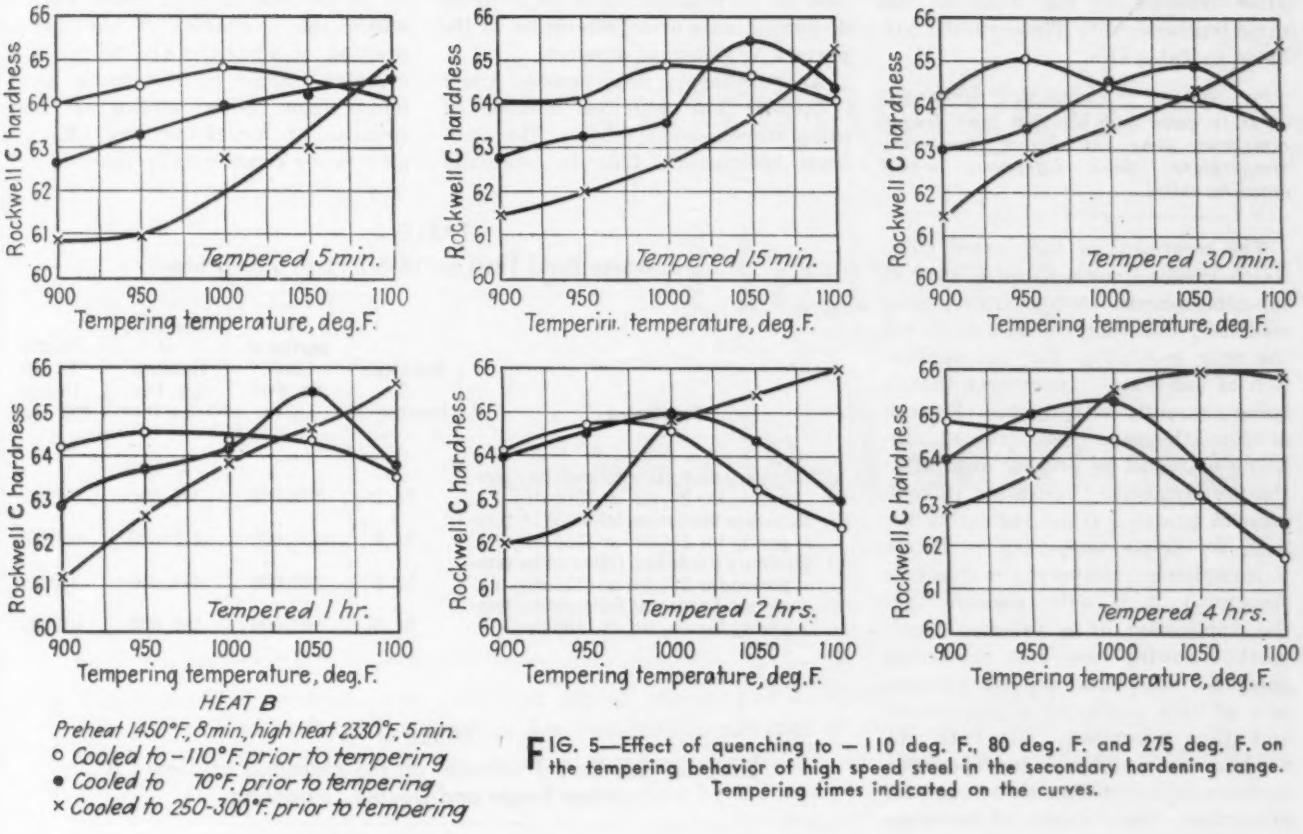

FIG. 5—Effect of quenching to −110 deg. F., 80 deg. F. and 275 deg. F. on the tempering behavior of high speed steel in the secondary hardening range. Tempering times indicated on the curves.

tinuously from the austenitizing temperature to sub-zero temperatures does not always result in an improved hardness after tempering is revealed by Figs. 3 and 4 which record the results of tempering experiments conducted within the secondary hardening range only. Examination of Fig. 3 reveals that even at normal tempering temperatures of between 1000 and 1050 deg. F. high speed steel samples which have been cooled to room temperature are often superior in hardness to those which have been cooled to —110 deg. F. in a mixture of dry ice and alcohol. It is apparent that the maximum secondary hardness is attained in the sub-zero treated specimens at a lower temperature—and in a shorter time (see Fig. 4)—than that for specimens in which the cooling was stopped at room temperature. At tempering temperatures of 900 and 950 deg. F. the samples which have been treated at sub-atmospheric temperatures are considerably superior in hardness, while at tempering temperatures of 1050 and 1100 deg. F. the reverse is true.

The results shown in Figs. 3 and 4 are verified in Fig. 5 which records the data obtained from a series of experiments on Steel B. Included also was a study of the effect of arresting the cooling during the quench at a temperature considerably in excess of room temperature. A complete study of the effect of such arrested quenching on the tempering of high speed steel has been recently published by Gordon, Cohen and Rose[4].

[4] *M. P. Gordon, M. Cohen, and R. S. Rose, "Effect of Quenching Bath Temperature on the Tempering of High Speed Steel" Preprint Number 34, A.S.M. 1943.*

Knowledge of this behavior is important since in many commercial heat treating procedures high speed steel is never permitted to reach room temperature prior to the initial tempering operation. As would be expected from the trend shown in Figs. 3 and 4, arresting the cooling at a temperature between 250 and 300 deg. F. results in a further increase in the temperature required to obtain maximum secondary hardness, while at the lower tempering temperatures such specimens show exceptionally low hardness values. Data assembled from the work of Gordon, Cohen and Rose[4] confirm this finding.

In tempering, the decomposition of austenite must be preceded by the precipitation of complex alloy carbides at the tempering temperature. The subsequent lowering of the alloy content of the retained austenite enables its transformation to martensite on cooling to room temperature. It is natural to assume that it will take a longer time to decompose large amounts of austenite than small amounts. Thus, after tempering at low tempering temperatures within the secondary hardening range the steel in which the initial cooling is stopped at or above room temperature will still contain quantities of retained austenite and will possess lower hardness values than the steel which was initially cooled to sub-zero temperatures. After tempering at higher tempering temperatures the large quantities of martensite in the latter steel have begun to soften slightly while the former steel is approaching its maximum hardness closely associated with, but slightly preceding, the complete transformation of retained austenite.

When room temperature is reached, therefore, assuming complete transformation of all of the retained austenite, specimens which have been subjected to sub-atmospheric temperatures should consist of 90 per cent tempered martensite and 10 per cent untempered martensite; specimens which have been quenched to room temperature should consist of 80 per cent tempered martensite and 20 per cent untempered martensite; whereas specimens in which the cooling has been stopped at a temperature of 275 deg. F. will probably consist of 35 per cent tempered martensite and 65 per cent untempered martensite.

Isolated experiments of multiple tempering have indicated that the differential in hardness created between these specimens after single tempering is partially maintained

after retempering for 2 hr. at the same temperature*. These results are listed in Table II.

**It is quite possible that with longer tempering times or higher tempering temperatures these differences would cease to exist.*

The treatment of high speed steel, which involves subjecting the steel to sub-atmospheric temperatures immediately following the quench, is not the only possibility for the application of sub-zero temperatures that is being currently investigated. Since it is often the case that retained austenite may still be present even after the first tempering operation in commercial practice (thus indicating the need for triple tempering to obtain a completely tempered martensitic structure) it is quite possible that the application of a sub-zero treatment following the first tempering operation will cause the transformation of this austenite to martensite and thus essentially eliminate the need for a third tempering operation in order to achieve the same physical properties. The dangers of breakage are reduced if this procedure is followed since a large part of the structure is tempered martensite. In direct cooling to sub-zero temperatures following the quench only untempered martensite is present and a certain percentage of breakage can occur.

The sub-zero treatment has also been applied to "fully tempered" tools of high speed steel with apparent increases in tool life. If such a treatment proves to be reliable and useful its basis must lie in either the transformation of small amounts of retained austenite to martensite or in some new phenomenon which may unsuspectedly be occurring during the cold treatment, such as a precipitation of carbide particles in a finely dispersed state or an alteration in the pattern of internal stresses.

As with every new process, there is almost an unlimited number of attempts made to develop the optimum treatment. This is especially so in the case of high speed steel in which the mechanics of the decomposition of austenite are normally so complex. Some of the many treatments now being attempted show promise of increasing tool life and may prove commercially feasible.

TABLE I

Transverse Bend Tests on 18-4-1 High Speed Steel[3]

Treatment	Rockwell C Hardness	Proportional Limit, Lb. Per Sq. In.	Modulus of Rupture, Lb. Per Sq. In.	Plastic Strain, Inches Per Inch

1050	4 hr.	63.3	63.7	64.7	64.4
1100	30 min.	63.7	62.4	64.6	63.3
1100	4 hr.	61.3	61.3	63.6	62.6

* The hardness values recorded under the columns headed "Double Tempering" were all obtained after retempering the indicated specimens for 2 hr. at the indicated temperature, regardless of the initial tempering time of these specimens

Bearing Classification System for Small Motors

SMALL precision-type motors are assembled with bearings previously selected to match the diameter of the fits as the result of a method developed by R. R. Cameron, foreman at one of General Electric's plants.

New ball bearings as received are first checked on a series of pin gages to classify them according to inside diameter. Each gage is 0.0001 in. different in size. These sizes are arranged to spread over the usual bore tolerance of precision bearings and usually about four gages or pins are necessary. After each bearing is tried on a pin, it is placed in a tray marked with the size of the pin on which it was a snug fit.

Next these bearings are checked on a comparator dial gage for outside diameter and placed in rows in each tray according to 0.0001 in. variation in o.d. A comparator plug gage is used to determine the size of the bearing seat in the end shields and a suitable bearing is pressed into place. Not only is this bearing chosen from the correct row in the tray to fit the end shield, but the particular tray i.d. identification is noted in order to control the rotor fit. Each rotor is checked with a series of Carboloy ring gages 0.0001 in. different in size and the proper shaft is chosen to fit the bearing, depending on the fit desired.

With the bearings classified both according to outside and inside diameter, the proper size for both the shaft and end shield at hand can be chosen easily, and the unit assembled has the desired accuracy.

Submerged Heating Speeds Pickling

By THOMAS E. LLOYD
Associate Editor, THE IRON AGE

. . . The use of submerged combustion burners for heating pickling tanks has resulted in savings of time, acid, and equipment, as well as better working conditions in steel mill pickling departments, according to a survey of users of this equipment.

CONSIDERABLE success has been experienced in the use of submerged heating of pickling tanks in bar, wire, tube, sheet, and plate pickling. Installations of this equipment, built by the Submerged Combustion Co. of America, Inc., Hammond, Ind., are in operation in some of the largest and most modern steel plants in the country as well as in various heavy equipment manufacturing plants and navy yards. In a survey of several of the users of submerged heating equipment for heating pickling baths, the conclusion that it was very clean, economical, and very easy to maintain was general.

Actually, submerged heating dates back to the development of the first submerged combustion burner in 1887, a burner that was ignited by hand and lowered into the vat to be heated. However, the material used in the construction of this type burner was not corrosion resistant and was not particularly valuable for use in acid solution.

The modern version of the submerged combustion burner, which is only about six years old, has a simple and reliable system for ignition and control. The starting button actuates an especially designed gas-and-air compressor. The compressor delivers the products of combustion at a pressure sufficient to overcome the head of liquid that fills the combustion chamber and part of the burner tank. As the compressed air drives the solution from the burner, a hot wire igniter is heated to incandescence by the passage of a high-amperage low-voltage current, and, after a predetermined time, a flow of pilot gas is admitted to the igniter chamber where it is ignited. The main gas flow is then directed into the main burner where it is ignited by the pilot flame. The air-gas ratio is controlled automatically to give combustion efficiency. The set-up of this ignition and control system can be seen in Fig. 1.

When the main gas flame is ignited, the burner controls lock into a running position until the desired solution temperature is reached, when a thermostat acts to shut off the gas flow. The air continues to flow through the system to maintain a fixed rate of agitation regardless of solution temperature. When the solution cools the thermostat again acts and the controls re-cycle to automatically establish and ignite the gas flow. Solution temperatures can be maintained as close as 0.5 deg. F. if necessary, but for normal operation the control range is usually set at from 3 to 5 deg. F.

In steel mill pickling, one of the unique advantages of the system is the maintenance of temperature with agitation of the bath, plus the fact that there is no dilution of the bath because of steam being introduced into it. On the contrary, the bath actually becomes slightly more concentrated because of evaporation of the water facilitated by the agitation at the higher temperatures.

The products of combustion in this system of bath heating are discharged directly into the tank bath, creating a very active agitation which would be almost impossible to duplicate mechanically. Such agitation and controlled temperature are claimed to reduce pickling time on certain grades of steel as much as 70 per cent over the steam heated bath.

Tube Etching

At one particular plant that manufactures high grade welded tubing, the use of submerged heating had

TABLE I
Operations Required

Steam Heated Tank	Submerged Combustion Heated Tank
Pickle, sulphuric acid	Pickle, sulphuric acid, submerged heating
Rinse in steam heated tank	Cold rinse
Lime dip, steam heated tank	Lime rinse, submerged heating
Special etch, steam heated	Dip in drawing compound (eliminate bench lubrication entirely)
Rinse	
Dip in drawing compound (either in tank or at drawing bench)	

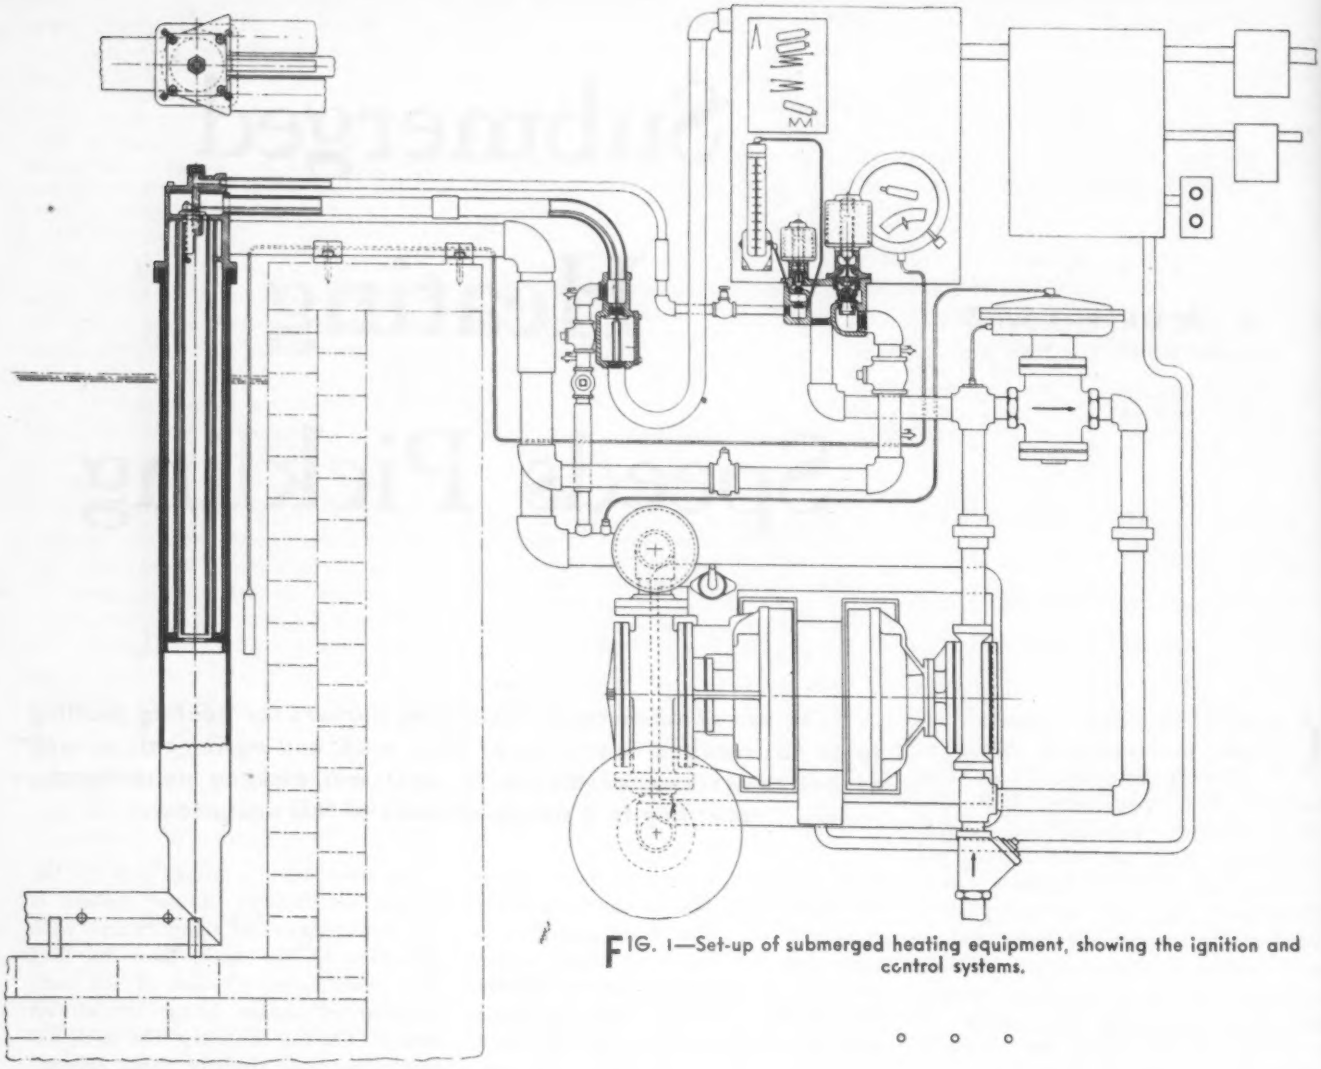

FIG. 1—Set-up of submerged heating equipment, showing the ignition and control systems.

o o o

some very specific advantages. Previously six operations were required to get the desired results, but the new practice enabled the elimination of two of these operations. These set-ups are shown in Table I and the present layout is illustrated in Fig. 2.

In a normal day's operation, some 900,000 ft. of tubing are handled through the pickling department of this plant, and all of it is now handled in the tanks equipped with submerged heating equipment. About 75 per cent of the work must undergo further drawing which formerly required a heavy drawing compound, but now a dip lubricant proves sufficient. Furthermore, with previous equipment it was estimated that from 750,000 to 1,200,000 B.t.u.'s per hr. input was necessary to maintain operating temperatures, whereas with the immersed heat-exchanger burners the input runs only about 250,000 B.t.u.'s per hr.

In this operation, the purpose is somewhat different from normal steel mill purpose for pickling. In the tube pickling, it is not primarily the intent to remove mill scale but to produce an etched surface on the cold-finished tubing. This etched surface facilitates further cold drawing.

The tubing is all electric resistance welded from strip steel. To procure the desired etch is more difficult and exacting than the removal of scale, and instead of using inhibitors to retard the acid attack on the metal, stronger acid solutions, higher temperatures, and longer immersion times are employed. With previous pickling facilities, this work could not be accomplished as completely as now, so comparison of costs between the two

TABLE II

Unit No.	Heat Input, B.t.u.	Tank Capacity, Gal.	Acid Content of Bath	Operating Temperature, Deg. F.	Operating Cycle, Min.	Products Pickled in Tank
1	1,500,000	6500	6 to 10	165–170	30–40	Carbon and alloy bars
2	1,500,000	6500	6 to 10	165–170	30–40	Carbon and alloy bars
3	1,500,000	6500	6 to 10	165–170	30–40	Carbon and alloy bars
4	750,000	5300	6 to 10	165–170	25–45	Wire rods
5	500,000	2900	6 to 10	165–170	25–45	Wire rods
6	500,000	300	10 to 20	170–175	Varies	Pickle pointing

methods would not be practical. The present set-up would serve for scale removal if necessary.

Advantages pointed out by this manufacturer are that the pickling room is clean, practically dry, and free from acid fumes and steam at all times. Comfortable temperatures and working conditions are maintained. Furthermore, with the flame used for heating being beneath the surface, all heat is absorbed by the bath; the violent agitation of the bath produces a more rapid and uniform action on the work; and acid consumption is reduced considerably as the acid content of the bath is never diluted by condensation as is the case with the usual method of discharging steam into the tank.

Removal of fumes and steam created by the elevated tank temperatures is accomplished by blowing air across the top of the tanks and exhausting it from the opposite side. By this method, the tanks are entirely open on top for crane handling of the work and the fume removal is quite effective.

The acid tank is steel, rubber lined with acid-proof brick inside the rubber coating. The four tanks (pickle, rinse, lime, and lubricating) are set in a pit that is equipped with an acid-proof floor and walls. The space between the tanks and the walls is covered by removable concrete slabs which provide a smooth floor and convenient working platform for the workmen, yet leave the lower part of the tank accessible.

Plate and Sheet Pickling

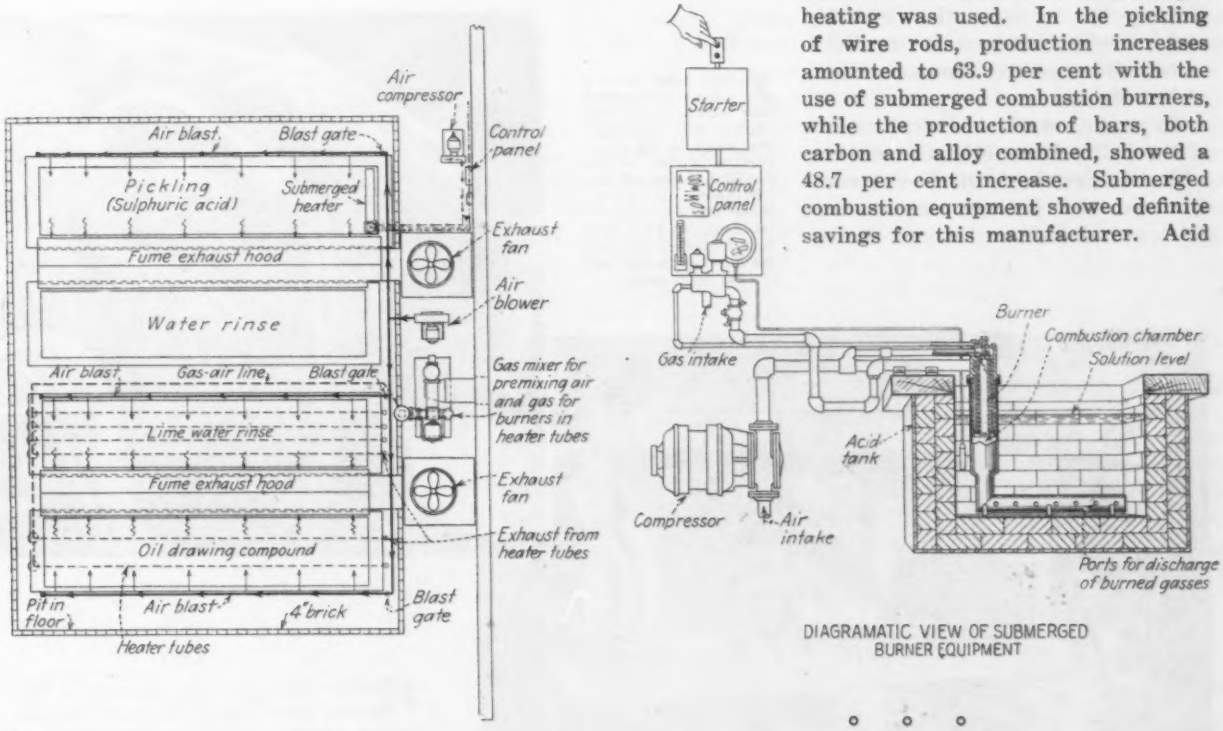
Another user of submerged heating equipment, a midwest steel plant that uses the equipped tanks for pickling steel sheets and plate, cites equally favorable results. In this case, two Rocker type pickling units are operated, one being heated with steam from the plant steam supply system and the other equipped with a submerged heating system using natural gas. The units are large, each having 1,500,000 B.t.u. rated input with a capacity of 6100 gal. and operating on an acid-water ratio of 8 to 92 per cent, at temperatures in the neighborhood of 185 deg. F. The operating cycle alone favors the submerged heating unit by 35 per cent, with the pickling time for the submerged heated tank 12 to 15 min., and for the steam heated tank ranging from 16 to 20 min. As the two picklers are operated at the same temperature, the gain in time is due entirely to greater agitation created by the submerged heating exhaust through the bath.

The faster pickling produces considerably greater tonnage, making it highly desirable where pickling capacity is limited. Furthermore, in plants where steam capacity is limited, submerged heating could be used, making unnecessary the installation of additional high cost steam generating facilities. This company reported that the costs of operating the two units were not separated. However, the burner and compressor service cost is known to be higher than the steam using acid-proof brass pipe, but the cost per ton produced with the increased tonnage afforded by the tanks with submerged heating is minor. The only objection registered was that operators of the units with submerged heating must be more skilled to obtain best over-all results.

Pointing and Rod Pickling

Another midwestern steel plant has been using submerged heating since 1934 and in 1939 went 100 per cent to this type of heating for pickling tanks. Carbon and alloy steel bars and wire rods are pickled and one unit is used for pickle pointing. Table II shows the set-up of these six units.

Time savings in production runs amounted to considerable, according to engineers at the company, varying from 50 to 140 per cent over previously used equipment. Likewise, production increased when submerged heating was used. In the pickling of wire rods, production increases amounted to 63.9 per cent with the use of submerged combustion burners, while the production of bars, both carbon and alloy combined, showed a 48.7 per cent increase. Submerged combustion equipment showed definite savings for this manufacturer. Acid



DIAGRAMATIC VIEW OF SUBMERGED BURNER EQUIPMENT

PLAN OF CARBON STEEL PICKLING LINE

o o o

costs were reduced 59.1 per cent below acid costs before the equipment was installed. Also, the use of boilers was eliminated, thus effecting a considerable saving. With the increased production permissible by the use of this equipment, a further saving in tank equipment was possible. Based on present production, it was estimated that two additional pickling tanks would be required to produce present steel requirements if the tanks were steam heated.

From the standpoint of operations, tests of fumes coming off the top of a vat heated by submerged combustion equipment contain about 50 per cent as much acid as the fumes coming from the top of an open steam-heated vat. An additional advantage is the ability to operate at lower temperatures. It is not necessary to increase the working temperature of a bath as the iron builds up in the solution. This phenomenon is probably caused by the suspended scale in the pickling solution causing an abrasive action against the steel. Also, the finished pickled product is uniform, making it unnecessary to return as much material to the pickling room for re-pickle.

The burners are able to withstand the action of sulphuric acid remarkably well, with the average unit in operation about 2½ years without burner replacement repairs being necessary. It is often necessary to replace igniters and other minor parts long before the burners, which are submerged in the acid, must be replaced.

At first it was felt that the inability of the combustion chamber to withstand a high iron content was objectionable. This point was about 26 Baume or 0.6 lb. of iron per gal. of solution. When the iron in the vat reached this point it would deposit on the lead coating of the burner where it acted as an insulator and caused the lead to burn out. After tests, however, it was shown that this was not an objectionable characteristic, because at such a point of iron content in the pickle bath, the solution falls off alarmingly. Therefore, it is considered wise not only from a burner standpoint to empty the vat and start in with fresh solution, but also considered economical from an acid-cost standpoint.

Welds X-Rayed on Large Fabricated Structure

ENGINEERING ingenuity was recently demonstrated in the successful application of X-ray inspection of welds at dizzy heights on a large fabricated structure. The application was to the "Baltimore Giant," a 250-ft. high fluid catalytic cracking unit erected by the M. W. Kellogg Co. in connection with the modernization program at the Baltimore refinery of the Standard Oil Co. of New Jersey.

To do this work, technical experts of the Kelley-Koett Mfg. Co., working with the Standard Oil Development Co. and the Kellogg organization, "stripped down" a standard Kelley-Koett 220,000 volt X-ray unit. After fitting the transformer units to special rigging, the equipment was hoisted from level to level by crane. The X-ray tube was lowered inside the tower and the film taped to the outside of the plates. Despite rainstorms and unavoidable jars and jolts, the X-ray inspection of welds in awkward locations went forward successfully and is believed to point to other applications in shipbuilding, plant construction and other heavy industry uses.

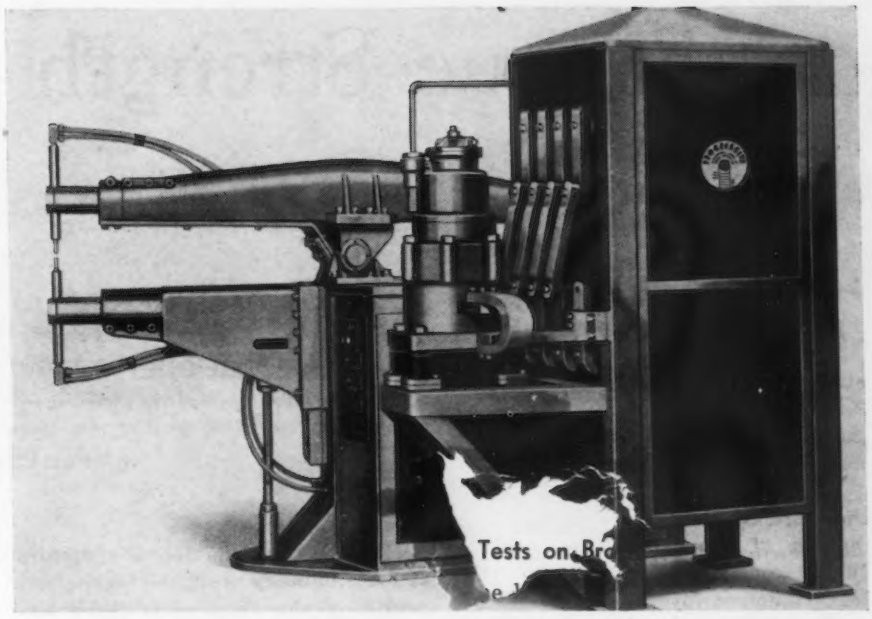
Storage Battery Resistance Welder Developed

o o o



STORAGE battery unit hooked up to a conventional rocker arm type spot welder. The batteries are encased in the housing at the right, with jumper connectors on the side. In the central foreground is the pneumatically actuated carbon disk, arcless interrupter. No transformers are involved.

o o o

WHAT is believed to be the first practical d.c. resistance welder using storage batteries as a source of welding current has been announced by Progressive Welder Co., 3050 E. Outer Drive, Detroit 12. The equipment is already in use, welding aluminum for aircraft assemblies.

Transformers associated with other types of stored energy welders are eliminated and by parallel connections of the battery cells large heavy current discharges in the range of 30,000 to 40,000 amp. are available at low voltage directly from the battery bus bars. Success of storage battery operated welders has been predicated on two new developments: The creation of a special battery design that will withstand repeated high discharge rates and the development of a contactor-controller capable of interrupting the heavy current without arcing.

The batteries have been evolved from ones designed to meet certain naval requirements in the war. Power for charging them is supplied from a normal a.c. power line, either single or three phase, and is converted to d.c. through a dry-disk type rectifier, normally requiring no attention. For an average welder, the rectifier draws only about 10 kva. Hence this equipment can be used for welding aluminum in areas where power supply limitations have prevented the use even of other types of stored energy welders, which are generally rated around 40 kva. Conventional a.c. aluminum resistance welders are rated at 300-400 kva.

Control of the actual amount of welding current is furnished by a pneumatically actuated contractor which operates on the principle of the well-known carbon pile. In this contactor, the current is automatically varied simply by controlling the pressure between two carbon disks through an air operated piston and solenoid valve. When the pressure on the contractor drops to zero, current automatically stops flowing, making possible interruption of the welding current without arcing. Characteristics of the welding current impulse can be varied by adjustments of needle valves in the air line to the contactor. All that is needed to control the weld cycle is a simple, nonsynchronous sequence welding control together with a pedal operated switch to initiate the cycle. The control may be of the electronic type.

Low Operating Costs

Use of storage batteries for the power source is said to result in a material reduction not only in the initial cost of the welding installation but also in operating costs, particularly as to current consumption, maintenance costs and supervisory requirements. Use of direct current in a single "shot" reduces inductive losses in the welding "loop" and assures greater weld consistency since the current passing through the weld will be the same, regardless of how deeply a panel is inserted in the throat of the welder. Furthermore, the voltage drop from battery terminals to electrodes is said to be only a fraction of that between the same electrodes and a conventional transformer. The only loss in the storage battery type of installation is that due to low electrical resistance in the cables and conductors themselves.

Several types of progressive resistance welders—rocker arm, pedestal and gun types—may be used in combination with the storage battery power unit. From the operator's standpoint, the actual welding procedure is similar to welding with conventional welders.

Unity Power Factor

Of particular importance in plants where other forms of equipment aside from welders are being operated is the fact that storage battery welders operate with virtually unity power factor. This makes unnecessary the installation of corrective electrical equipment for highly reactive loads associated with conventional forms of a.c. welding equipment. The low and constant line load imposed by the battery charger makes the equipment readily adaptable to communities where power supply is limited. In addition to its operating advantages, the use of storage battery equipment for resistance welding is said to provide a higher degree of safety, since there are no high voltage circuits involved in the system.

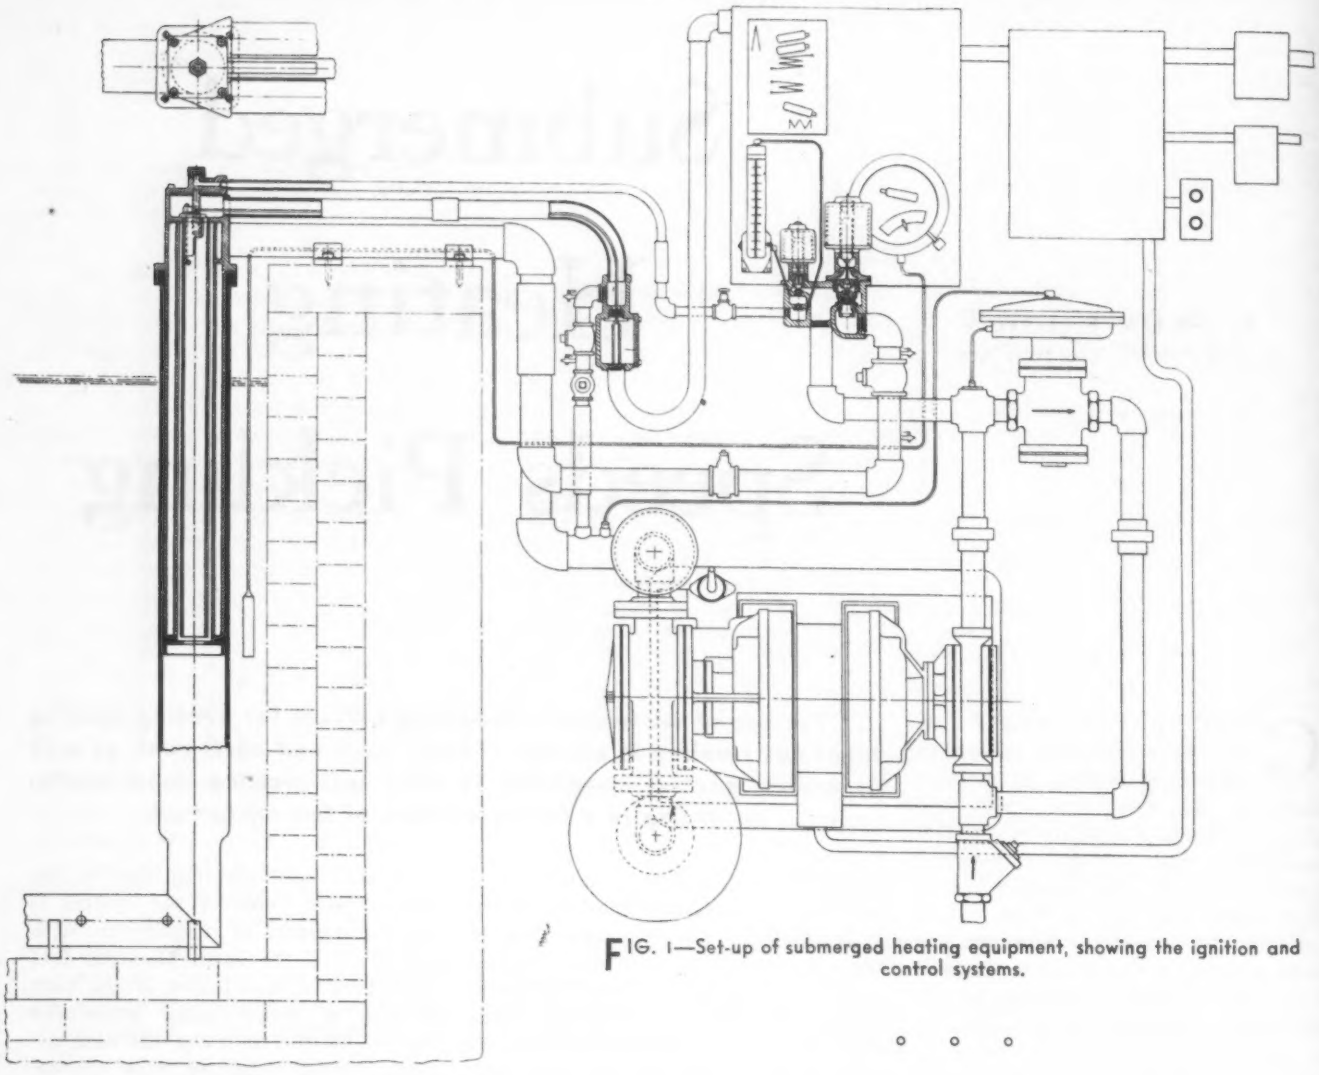


FIG. 1—Set-up of submerged heating equipment, showing the ignition and control systems.

o o o

some very specific advantages. Previously six operations were required to get the desired results, but the new practice enabled the elimination of two of these operations. These set-ups are shown in Table I and the present layout is illustrated in Fig. 2.

In a normal day's operation, some 900,000 ft. of tubing are handled through the pickling department of this plant, and all of it is now handled in the tanks equipped with submerged heating equipment. About 75 per cent of the work must undergo further drawing which formerly required a heavy drawing compound, but now a dip lubricant proves sufficient. Furthermore, with previous equipment it was estimated that from 750,000 to 1,200,000 B.t.u.'s per hr. input was necessary to maintain operating temperatures, whereas with the immersed heat-exchanger burners the input runs only about 250,000 B.t.u.'s per hr.

In this operation, the purpose is somewhat different from normal steel mill purpose for pickling. In the tube pickling, it is not primarily the intent to remove mill scale but to produce an etched surface on the cold-finished tubing. This etched surface facilitates further cold drawing.

The tubing is all electric resistance welded from strip steel. To procure the desired etch is more difficult and exacting than the removal of scale, and instead of using inhibitors to retard the acid attack on the metal, stronger acid solutions, higher temperatures, and longer immersion times are employed. With previous pickling facilities, this work could not be accomplished as completely as now, so comparison of costs between the two

TABLE II

Unit No.	Heat Input, B.t.u.	Tank Capacity, Gal.	Acid Content of Bath	Operating Temperature, Deg. F.	Operating Cycle, Min.	Products Pickled in Tank
1	1,500,000	6500	6 to 10	165–170	30–40	Carbon and alloy bars
2	1,500,000	6500	6 to 10	165–170	30–40	Carbon and alloy bars
3	1,500,000	6500	6 to 10	165–170	30–40	Carbon and alloy bars
4	750,000	5300	6 to 10	165–170	25–45	Wire rods

6	500,000	300	10 to 20	170–175	Varies	Pickle pointing

methods would not be practical. The present set-up would serve for scale removal if necessary.

Advantages pointed out by this manufacturer are that the pickling room is clean, practically dry, and free from acid fumes and steam at all times. Comfortable temperatures and working conditions are maintained. Furthermore, with the flame used for heating being beneath the surface, all heat is absorbed by the bath; the violent agitation of the bath produces a more rapid and uniform action on the work; and acid consumption is reduced considerably as the acid content of the bath is never diluted by condensation as is the case with the usual method of discharging steam into the tank.

Removal of fumes and steam created by the elevated tank temperatures is accomplished by blowing air across the top of the tanks and exhausting it from the opposite side. By this method, the tanks are entirely open on top for crane handling of the work and the fume removal is quite effective.

The acid tank is steel, rubber lined with acid-proof brick inside the rubber coating. The four tanks (pickle, rinse, lime, and lubricating) are set in a pit that is equipped with an acid-proof floor and walls. The space between the tanks and the walls is covered by removable concrete slabs which provide a smooth floor and convenient working platform for the workmen, yet leave the lower part of the tank accessible.

Plate and Sheet Pickling

Another user of submerged heating equipment, a midwest steel plant that uses the equipped tanks for pickling steel sheets and plate, cites equally favorable results. In this case, two Rocker type pickling units are operated, one being heated with steam from the plant steam supply system and the other equipped with a submerged heating system using natural gas. The units are large, each having 1,500,000 B.t.u. rated input with a capacity of 6100 gal. and operating on an acid-water ratio of 8 to 92 per cent, at temperatures in the neighborhood of 185 deg. F. The operating cycle alone favors the submerged heating unit by 35 per cent, with the pickling time for the submerged heated tank 12 to 15 min., and for the steam heated tank ranging from 16 to 20 min. As the two picklers are operated at the same temperature, the gain in time is due entirely to greater agitation created by the submerged heating exhaust through the bath.

The faster pickling produces considerably greater tonnage, making it highly desirable where pickling capacity is limited. Furthermore, in plants where steam capacity is limited, submerged heating could be used, making unnecessary the installation of additional high cost steam generating facilities. This company reported that the costs of operating the two units were not separated. However, the burner and compressor service cost is known to be higher than the steam using acid-proof brass pipe, but the cost per ton produced with the increased tonnage afforded by the tanks with submerged heating is minor. The only objection registered was that operators of the units with submerged heating must be more skilled to obtain best over-all results.

Pointing and Rod Pickling

Another midwestern steel plant has been using submerged heating since 1934 and in 1939 went 100 per cent to this type of heating for pickling tanks. Carbon and alloy steel bars and wire rods are pickled and one unit is used for pickle pointing. Table II shows the set-up of these six units.

Time savings in production runs amounted to considerable, according to engineers at the company, varying from 50 to 140 per cent over previously used equipment. Likewise, production increased when submerged heating was used. In the pickling of wire rods, production increases amounted to 63.9 per cent with the use of submerged combustion burners, while the production of bars, both carbon and alloy combined, showed a 48.7 per cent increase. Submerged combustion equipment showed definite savings for this manufacturer. Acid

o o o

costs were reduced 59.1 per cent below acid costs before the equipment was installed. Also, the use of boilers was eliminated, thus effecting a considerable saving. With the increased production permissible by the use of this equipment, a further saving in tank equipment was possible. Based on present production, it was estimated that two additional pickling tanks would be required to produce present steel requirements if the tanks were steam heated.

From the standpoint of operations, tests of fumes coming off the top of a vat heated by submerged combustion equipment contain about 50 per cent as much acid as the fumes coming from the top of an open steam-heated vat. An additional advantage is the ability to operate at lower temperatures. It is not necessary to increase the working temperature of a bath as the iron builds up in the solution. This phenomenon is probably caused by the suspended scale in the pickling solution causing an abrasive action against the steel. Also, the finished pickled product is uniform, making it unnecessary to return as much material to the pickling room for re-pickle.

The burners are able to withstand the action of sulphuric acid remarkably well, with the average unit in operation about 2½ years without burner replacement repairs being necessary. It is often necessary to replace igniters and other minor parts long before the burners, which are submerged in the acid, must be replaced.

At first it was felt that the inability of the combustion chamber to withstand a high iron content was objectionable. This point was about 26 Baume or 0.6 lb. of iron per gal. of solution. When the iron in the vat reached this point it would deposit on the lead coating of the burner where it acted as an insulator and caused the lead to burn out. After tests, however, it was shown that this was not an objectionable characteristic, because at such a point of iron content in the pickle bath, the solution falls off alarmingly. Therefore, it is considered wise not only from a burner standpoint to empty the vat and start in with fresh solution, but also considered economical from an acid-cost standpoint.

Welds X-Rayed on Large Fabricated Structure

ENGINEERING ingenuity was recently demonstrated in the successful application of X-ray inspection of welds at dizzy heights on a large fabricated structure. The application was to the "Baltimore Giant," a 250-ft. high fluid catalytic cracking unit erected by the M. W. Kellogg Co. in connection with the modernization program at the Baltimore refinery of the Standard Oil Co. of New Jersey.

To do this work, technical experts of the Kelley-Koett Mfg. Co., working with the Standard Oil Development Co. and the Kellogg organization, "stripped down" a standard Kelley-Koett 220,000 volt X-ray unit. After fitting the transformer units to special rigging, the equipment was hoisted from level to level by crane. The X-ray tube was lowered inside the tower and the film taped to the outside of the plates. Despite rainstorms and unavoidable jars and jolts, the X-ray inspection of welds in awkward locations went forward successfully and is believed to point to other applications in shipbuilding, plant construction and other heavy industry uses.

STORAGE battery unit hooked up to a conventional rocker arm type spot welder. The batteries are encased in the housing at the right, with jumper connectors on the side. In the central foreground is the pneumatically actuated carbon disk, arcless interrupter. No transformers are involved.

o o o

WHAT is believed to be the first practical d.c. resistance welder using storage batteries as a source of welding current has been announced by Progressive Welder Co., 3050 E. Outer Drive, Detroit 12. The equipment is already in use, welding aluminum for aircraft assemblies.

Transformers associated with other types of stored energy welders are eliminated and by parallel connections of the battery cells large heavy current discharges in the range of 30,000 to 40,000 amp. are available at low voltage directly from the battery bus bars. Success of storage battery operated welders has been predicated on two new developments: The creation of a special battery design that will withstand repeated high discharge rates and the development of a contactor-controller capable of interrupting the heavy current without arcing.

The batteries have been evolved from ones designed to meet certain naval requirements in the war. Power for charging them is supplied from a normal a.c. power line, either single or three phase, and is converted to d.c. through a dry-disk type rectifier, normally requiring no attention. For an average welder, the rectifier draws only about 10 kva. Hence this equipment can be used for welding aluminum in areas where power supply limitations have prevented the use even of other types of stored energy welders, which are generally rated around 40 kva. Conventional a.c. aluminum resistance welders are rated at 300-400 kva.

Control of the actual amount of welding current is furnished by a pneumatically actuated contractor which operates on the principle of the well-known carbon pile. In this contactor, the current is automatically varied simply by controlling the pressure between two carbon disks through an air operated piston and solenoid valve. When the pressure on the contractor drops to zero, current automatically stops flowing, making possible interruption of the welding current without arcing. Characteristics of the welding current impulse can be varied by adjustments of needle valves in the air line to the contactor. All that is needed to control the weld cycle is a simple, nonsynchronous sequence welding control together with a pedal operated switch to initiate the cycle. The control may be of the electronic type.

Low Operating Costs

Use of storage batteries for the power source is said to result in a material reduction not only in the initial cost of the welding installation but also in operating costs, particularly as to current consumption, maintenance costs and supervisory requirements. Use of direct current in a single "shot" reduces inductive losses in the welding "loop" and assures greater weld consistency since the current passing through the weld will be the same, regardless of how deeply a panel is inserted in the throat of the welder. Furthermore, the voltage drop from battery terminals to electrodes is said to be only a fraction of that between the same electrodes and a conventional transformer. The only loss in the storage battery type of installation is that due to low electrical resistance in the cables and conductors themselves.

Several types of progressive resistance welders—rocker arm, pedestal and gun types—may be used in combination with the storage battery power unit. From the operator's standpoint, the actual welding procedure is similar to welding with conventional welders.

Unity Power Factor

Of particular importance in plants where other forms of equipment aside from welders are being operated is the fact that storage battery welders operate with virtually unity power factor. This makes unnecessary the installation of corrective electrical equipment for highly reactive loads associated with conventional forms of a.c. welding equipment. The low and constant line load imposed by the battery charger makes the equipment readily adaptable to communities where power supply is limited. In addition to its operating advantages, the use of storage battery equipment for resistance welding is said to provide a higher degree of safety, since there are no high voltage circuits involved in the system.

Fatigue Strength Properties

By GEORGE SACHS
and
GEORGE ESPEY
Case School of Applied Science, Cleveland

THE values of yield strength and tensile strength specified by the Armed Forces for the principal structural aircraft tubing steel SAE X4130, listed in Table I, cannot be guaranteed in the conventionally annealed or normalized conditions.

Special heat treating [illegible] therefore, are being [illegible] duction of commercial [illegible] tubing, consisting either of [illegible]ing (followed by a controlled air quench and a stress relief anneal) or by a stress relief anneal, that is, an incomplete process anneal, of the cold finished tubing. While these two conditions differ slightly in their tensile properties, both can be readily produced to conform to specifications given in Table I, page 67.

Their microstructures differ in that normalizing results in a somewhat indistinct martensite-like structure, Fig. 1, while the stress-relieved tubing partially retains the fibered structure of longitudinally stretched ferrite and pearlite grains acquired in cold drawing, Fig. 2.

The investigation was undertaken in order to determine how the two conditions compared in regard to their fatigue strength properties.

At present, the most common procedure used in determining the fatigue strength of tubing is to machine round or flat test bars from the wall of the tubing, but only rather thick walled tubing can be tested in this manner.

A few tests have been carried out on tubular specimens taken from relatively small sizes of tubing, using the common, rotary beam type, fatigue machines, designed for the testing of round specimens.[1]

Following this practice, tubular fatigue specimens were used* to determine the effect of both normalizing and stress relief finishing treatments on various fatigue strength characteristics of SAE X4130 tubing. In addition to the regular fatigue strength, the endurance properties were determined in the presence of the three major types of stress raisers: Notches, lateral pressure (chafing or fretting) and corrosion.[2, 3, 4]

Two sizes of tubing were selected.

**The Farmer rotating beam type of machine, extensively appplied to testing solid specimens, was used for testing the tubular specimens, at a speed of approximately 3500 cycles per minute.*

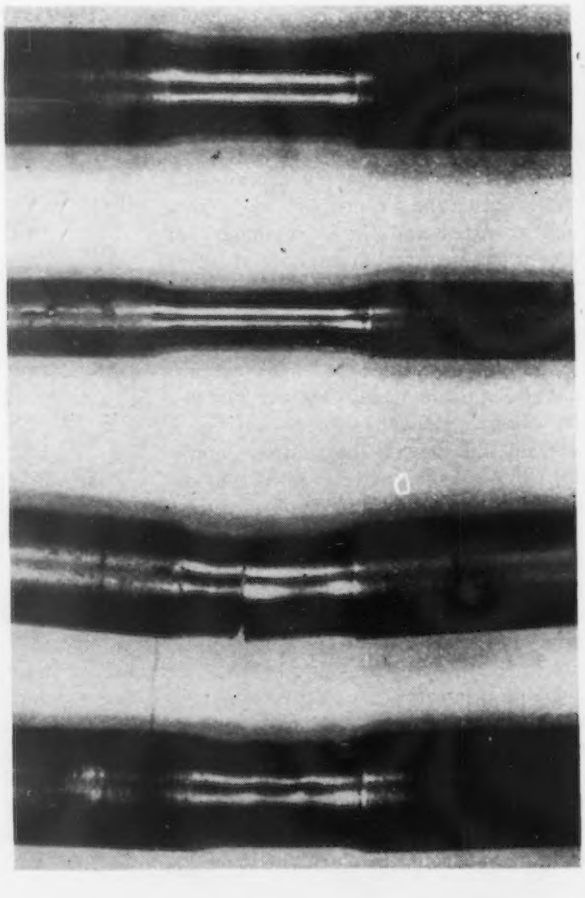
FIG. 3—Specimens developed for regular fatigue tests. For ⅝ to ¾ in. the wall of the specimen was reduced and polished longitudinally to 40 to 45 per cent of the original area. If the reduced area is longer than ¾ in., the larger diameter specimens show a pronounced tendency to buckle.



# of SAE X4130 Tubing

. . . Most widely used material for aircraft structures is normalized or stress relieved SAE X4130 tubing. This report on the research project conducted under the sponsorship of the Ohio Seamless Tube Co., Shelby, Ohio, discusses the effect of normalizing and stress relief annealing on the fatigue strength properties of this commercial tubing.

The dimensions, the last stages of the manufacturing procedure and the chemical and tensile properties of the various lots of tubing are assembled in Table I, page 67.

Tests on Polished Specimens

The specimens developed for the regular fatigue tests, Figs. 3 and 4, were characterized by the following features: The wall, for a certain length, was reduced and polished longitudinally to 40 to 45 per cent of the original area.* The maximum length of the reduced section of the specimens was ⅝ to ¾ in., because the larger diameter (9/16 in.) specimens had a pronounced tendency to buckle under the relatively high loads if the reduced portion was longer, Fig. 3. A fillet radius of ½ in. connecting the reduced section and the original portion was sufficiently generous to prevent significant stress concentration at any point in the specimen. This was proved since all failures in regular fatigue broke in the cylindrical portion of reduced sections some distance away from the fillet. The inner surface of each specimen was cleaned and inspected in order to insure the absence of seams and scratches.

**In order to entirety avoid failure in the grips from chafing fatigue, it was found that, for this steel having a strength of 100,000 to 120,000 lb. per sq. in., the ratio of reduced section to original section should be below 0.35.*

Five to eight specimens, subjected to different bending loads, were found to be sufficient to determine the regular fatigue strength within ± 2000 lb. per sq. in., or better than ± 5 per cent.

According to the results, Fig. 4, the fatigue strength values of commercial SAE X4130 tubing, having approximately the same tensile properties, but differing in size and in manufacture, vary considerably. The 60,000 lb. per sq. in. fatigue strength of the ⅜ in. diameter, stress relieved tubing amounted to 50 per cent of the tensile strength, while the 39,000 lb. per sq. in. fatigue strength of the 9/16 in. diameter normalized tubing equaled only 32 per cent of its tensile strength, Table II, page 67.

More than half of this large spread in fatigue strength can be attributed to the finishing heat treatment, the fatigue strength of the normalized tubing being 11,000 lb. per sq. in., or about 20 per cent lower than that of the stress relieved tubing, for either of the sizes investigated.

In addition, the fatigue strengths of both conditions of the 9/16 in. diameter tubing were 10,000 lb. per sq. in. lower than those for the corresponding conditions of the ⅜ in. diameter tubing, which accounted for the remainder of the variation. The generally lower values of the 9/16 in. tubing may be caused partially by its tendency to buckle, Fig. 3, thus increasing the effective strain to an indeterminate extent. An insignificant difference in the chafing fatigue values for the two sizes of tubing would also indicate that the effect of buckling is considerable under higher loads, since the chafing fatigue specimens were tested under much lower loads than the regular fatigue specimens.

o o o

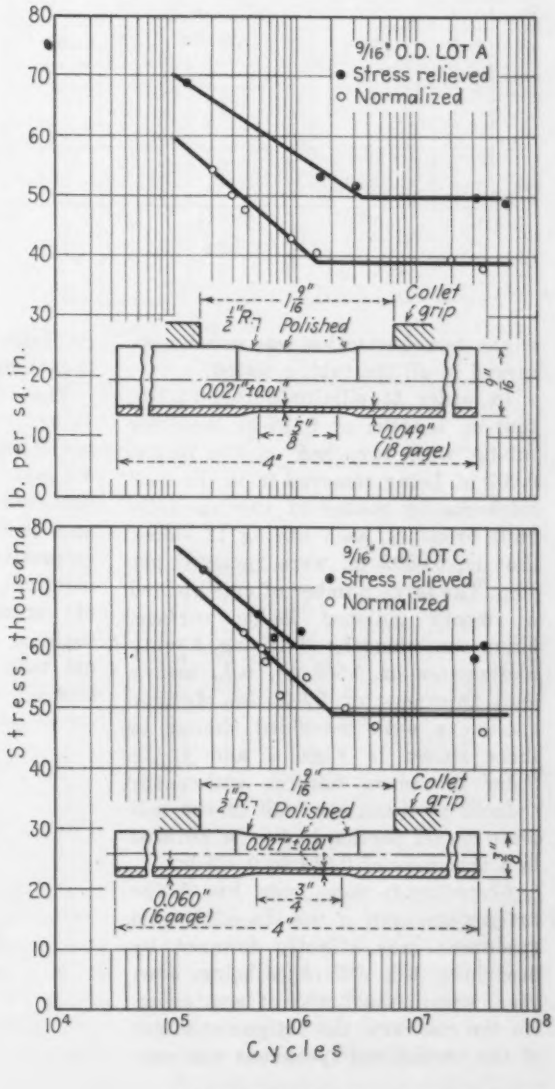


FIG. 4—Fatigue strength values of commercial SAE X4130 tubing having similar tensile properties but differing in size and manufacture vary considerably. Finishing heat treatment is the major factor in influencing fatigue strength.

Tests on Broached Specimens

The higher fatigue strength of the stress relieved than of the normalized tubing may be explained by corresponding differences in the quality of the inner surfaces. The higher temperature of normalizing may have resulted in a deeper decarburization than in the stress relief treatment. A

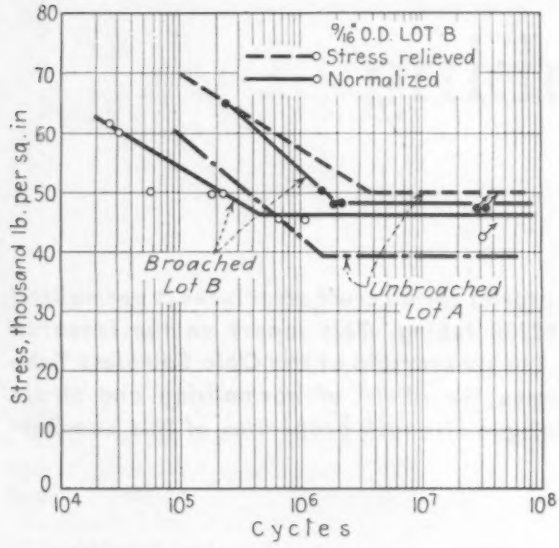

FIG. 5—Effect of broaching on fatigue strength of SAE X4130 tubing.

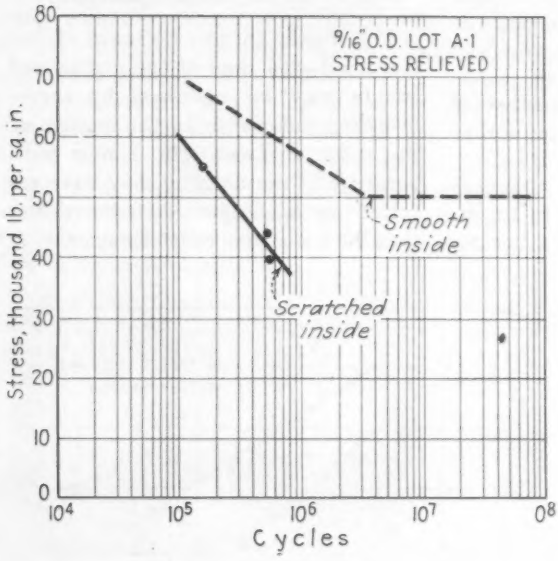

FIG. 6—Effect of inside scratches on regular fatigue strength of stress relieved SAE X4130 tubing.

slight decarburization was usually observed in all the tubing tested.

In order to eliminate this factor, four-in. lengths of 9/16-in. diameter tubing were broached on the inside, 0.005 in. being removed from the wall thickness by means of two specially built broaches, each having 12 steps; that is, 0.0002 in. were removed per step. The large number of cuts yielded a smooth polished inside surface. From these lengths of tubing, having a diameter of 0.565 in. o.d., and a wall thickness of 0.045 in., fatigue specimens were machined similar to those shown in Figs. 3 and 4. In order to secure failures within the reduced sections, the wall of the polished center portion had to be reduced to a thickness of 0.018 to 0.022 in.

According to these tests, Fig. 5, the fatigue strength of the stress relieved specimens was slightly lowered by broaching, this difference being, however, within the limits of scattering. On the contrary, the fatigue strength of the normalized specimens was considerably raised by the broaching of the inside.

The fatigue strength values for the stress relieved and normalized conditions, tested with a broached surface, 48,000 and 46,000 lb. per sq. in. respectively, were almost identical, within the limit of accuracy. However, such a comparison does not take into account the tensile strength of this stress relieved tubing (Lot B-1) which was considerably lower than the tensile strength of all the other investigated lots. Table I. Consequently, the ratio of fatigue strength to tensile strength was increased by broaching for both the stress relieved and normalized conditions by 0.04 and 0.07 respectively. Table II, page 67. Thus, the broaching only partially eliminated the difference in the fatigue strength ratios of the two conditions.

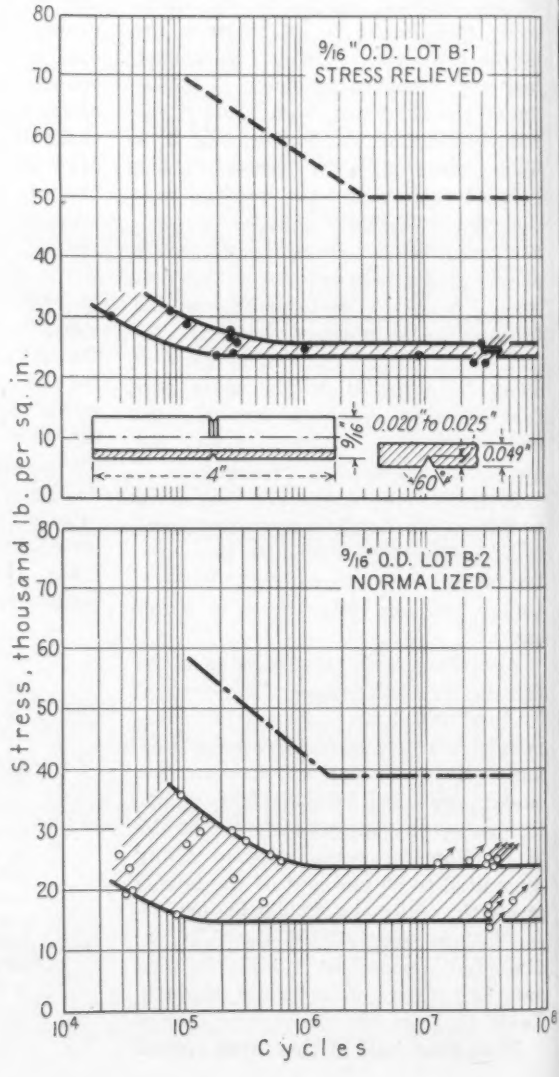
o o o

FIG. 7—Notch fatigue strength of SAE X4130 tubing.

Tests on Scratched Tubing

Some of the specimens prepared for the regular fatigue tests (without broaching) were found on inspection to exhibit deep "scratches" on the inside. Fatigue tests on such defective metal resulted in a considerably reduced life, Fig. 6. While the number of tests was not sufficient to establish a definite endurance limit for scratched tubing, their results indicate a fatigue strength of not over 35,000 lb. per sq. in., or 30 per cent lower than that of specimens with an unbroken surface.

This agrees with some similar tests



previously made on ½-in. diameter SAE 4130 steel tubing, heat treated to a tensile strength of over 200,000 lb. per sq. in.[1] For this steel, the fatigue strength of scratched specimens, 47,000 lb. per sq. in., was 30 per cent lower than that for unscratched tubing (67,000 lb. per sq. in.).

These results are difficult to explain. The effect of "notches" located in the direction of the straining (tension) should be small, according to general conceptions. However, it was observed that some of the scratched specimens exhibited longitudinal splits after failure, indicative of the development of transverse tension during loading.

Tests on Notched Specimens

In order to determine the effect of conventional notches, positioned perpendicular to the applied stress, specimens, 4 in. in length, cut from the 9/16 in. tubing were provided with a machined sharp 60-deg. V-notch,* having a depth of 0.020 to 0.025 in., or 40 to 50 per cent of the wall thickness, Fig. 7. Similar to the previously discussed fatigue strength values, the notch fatigue strength of tubing in the stress relieved condition was found to be superior to that in the normalized condition (without broaching), Fig. 7. In addition, normalized tubing differed from stress relieved tubing particularly with respect to the large scattering of the results. The lower limit of the scattering range for the normalized condition, 15,000 lb. per sq. in., was only 60 per cent of that for the stress relieved condition, 24,000 lb. per sq. in., while the upper limits of the scattering ranges differed only slightly.

There are various possible explanations for this peculiar discrepancy. First, it was observed that the vibrations, which are difficult to avoid in fatigue tests, considerably reduced the number of cycles for a given load for the normalized specimens, but did not noticeably affect the stress relieved specimens. Second, it appears possible that the normalized tubing varies over the length more than the stress relieved tubing. However, a large number of specimens in each condition would be required to establish definitely such differences between the two conditions of tubing.

Similar notch fatigue specimens of 9/16 in. tubing with a more shallow 60 deg. V notch, 0.012 ± .002 in. or approximately 25 per cent of the wall thickness, failed in chafing.

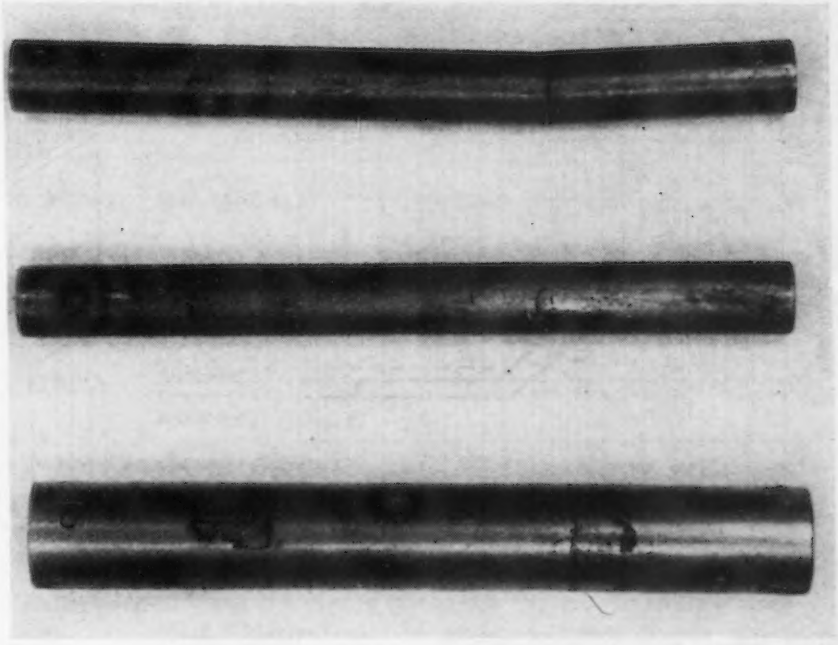


FIG. 8 — Chafing fatigue specimens need not be machined prior to testing. The pressure of the gripping collets constitutes an efficient stress raiser.

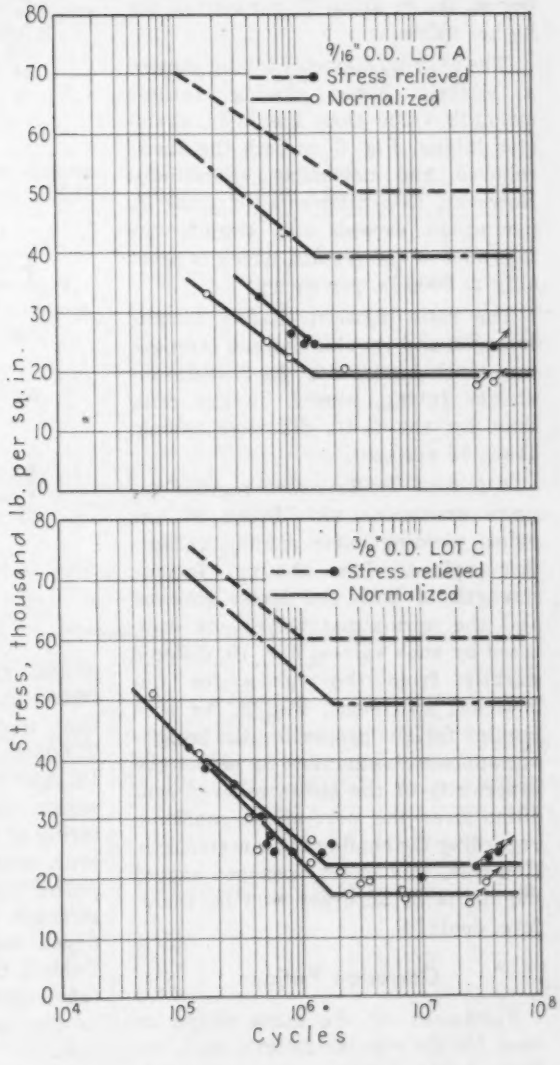

FIG. 9 — Chafing fatigue strength of SAE X4130 tubing.

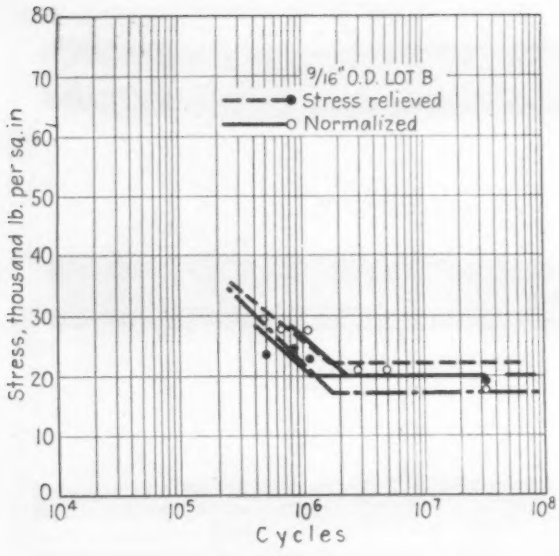
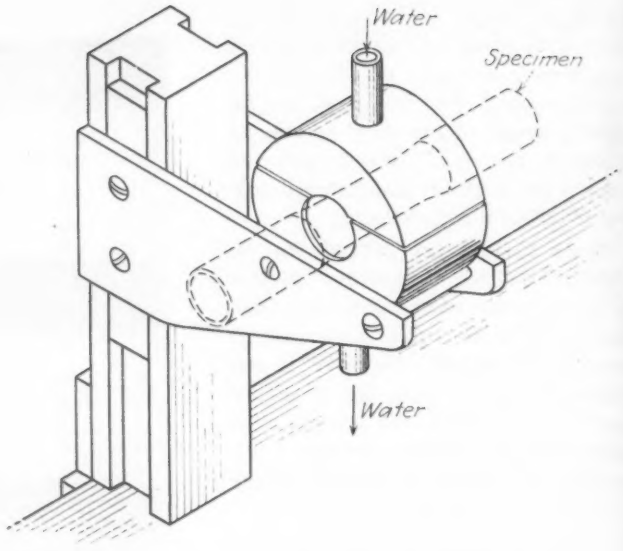
Chafing Fatigue Tests

The effect of lateral pressure as a stress raiser in fatigue can be determined in a particularly simple manner.[4] A suitable length, 4 in., of the tubing can be tested without any machining Fig. 8. The pressure of the gripping collets constitutes an efficient stress raiser, resulting in pitting and abrasion, called "chafing," or "fretting," and in fatigue breaks at the edge of the contact under comparatively low vibrating stresses.

The values of the chafing fatigue strength, Fig. 9, for the various tubing were found to be between 24,000 and 17,000 lb. per sq. in., and within the common limits of the values determined for small size round and flat rods of steels having the same strength as the SAE X4130 steel.[4]

The chafing fatigue strength values were again considerably higher for the stress relieved than for the normalized tubing. The difference, for





either size, is approximately 5000 lb. per sq. in., or about 20 per cent of the higher value.

The 9/16-in. diameter tubing showed a slightly lower chafing fatigue strength value than the ⅜-in. diameter tubing, Fig. 9, in both the stress relieved and normalized conditions. However, this difference of 2000 lb. per sq. in. exceeds only slightly the tolerance of the results, which is probably ± 2000 lb. per sq. in.

The ratio between chafing fatigue strength and regular fatigue strength was much higher for the 9/16-in. diameter tubing, almost 50 per cent, than for the ⅜-in. diameter tubing, about 35 per cent.

A few of the broached regular fatigue specimens also broke at the grips, yielding some chafing fatigue test values. The chafing fatigue strength of both the stress relieved and the normalized tubing, as indicated by such values, Fig. 10, differed slightly from the values for unbroached specimens, Fig. 9. As with regular fatigue properties, the broaching appears to eliminate or reduce the superiority of the stress relieved condition over the normalized condition regarding the chafing fatigue strength. However, this effect does not exceed the limits of accuracy and is, therefore, doubtful.

Corrosion Fatigue

Specimens of the same shape as used for the regular fatigue tests, see Figs. 3 and 4, were subjected simultaneously to rotational bending and to corrosion by running tap water, using the attachment illustrated in Fig. 11.

The stress relieved tubing appeared to possess only a slightly higher corrosion fatigue strength, 26,000 lb. per sq. in., than the normalized tubing, 25,000 lb. per sq. in., Fig. 12. The small difference is within the limits of scattering of the results. However, considering the comparatively low tensile strength of the stress relieved tubing (Lot B-1), Table I, this condition was found again to be superior to the normalized condition.

UPPER LEFT

FIG. 10.—Effect of broaching on chafing fatigue strength of SAE X4130 tubing.

o o o

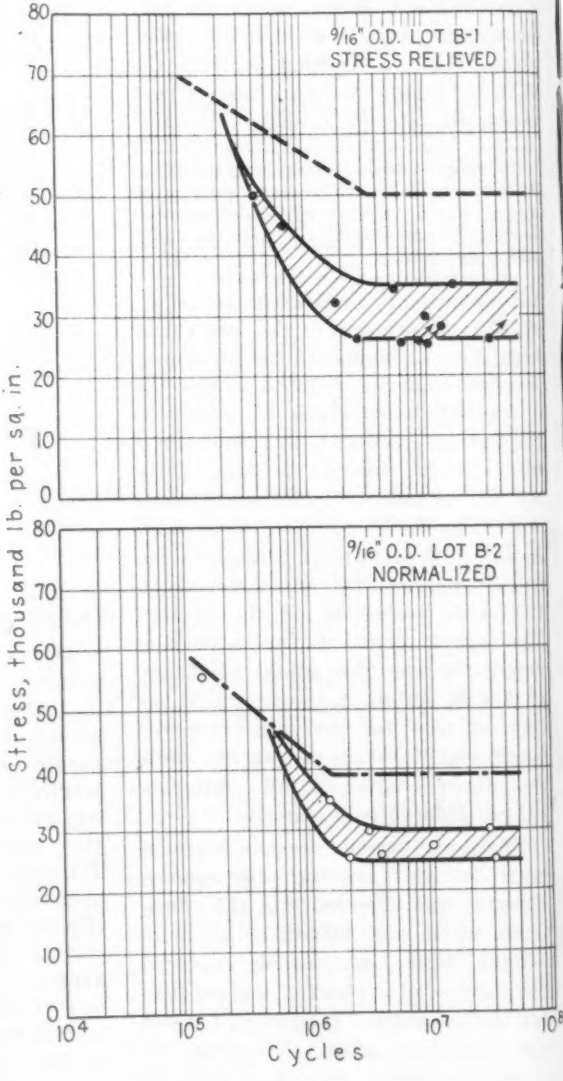
UPPER RIGHT

FIG. 11 — Attachment for corrosion fatigue tests.

o o o

RIGHT

FIG. 12—Corrosion fatigue strength of SAE X4130 tubing.



The absolute values of corrosion fatigue strength were surprisingly high in comparison to the values of the chafing and notch fatigue tests. This might be correlated with the observation that the corrosion fatigue breaks frequently occurred in the radius adjoining the reduced section of the tubing specimens, rather than in the cylindrical portion. In a number of specimens the cross section at the point of failure was greater than that of the cylindrical reduced portion. It appears that the corrosive attack is

more effective where it can progress in the longitudinal direction than where it can proceed only in the circumferential direction.

Tests on Welded Tubing

A few specimens, circumferentially butt welded with low carbon iron rod and SAE X4130 rod, failed at the grips. This showed the welds to be stronger with respect to vibrational strain than the portion of the tubing which was subjected to chafing.

Summary

SAE X4130 tubing, processed to a minimum tensile strength of 95,000 lb. per sq. in., was found to possess different fatigue strength properties, depending upon the manufacturing procedure.

The regular fatigue strength, notch fatigue strength, chafing fatigue strength and corrosion fatigue strength were always higher, in proportion to the tensile strength, for stress relieved than for normalized tubing.

Rather low regular fatigue strength values were determined for tubing having a very thin wall.

Broaching of the inside increased the various fatigue strength values of thin walled tubing, particularly in the normalized condition.

The results obtained show that numerous, as yet not entirely recognized factors, determine the fatigue strength properties of tubular structures. More extensive tests will be required to clarify the relations.

Measuring Errors in Involute S

HOW many of us have seen a machinist or an engineer pick up a pair of mating involute gears hold one in each hand, mesh them tightly together through a considerable arc and then pronounce them good or bad, according to how they "feel"? Such methods of inspection are at all times of doubtful value and not to be tolerated in modern industry. Involute gears will accommodate considerable variation in center distance, but because of this flexibility spur gears of the involute system are frequently subjected to much abuse and misunderstanding especially in regard to interpretation of errors.

If the errors in involute spur gears are to be correctly measured and interpreted, the purpose for which the gears are intended should be kept in mind. Spur gears are the practical solution to the mechanical problem of transmitting uniform rotary motion from one shaft to another parallel shaft at a definite ratio of rotative speeds. A spur gear may fail to transmit uniform rotary motion to its mating gear because of errors in itself or in its mate or both. If a gear fails to transmit uniform rotary motion that is, causes acceleration and deceleration in its mate, the section in itself will not only be objectionable but also will tend to induce failure of various types in the gears as well as other parts of the mechanism. Furthermore, if errors prevent a full bearing across the faces of the teeth stress concentration may cause rapid wear on surface fatigue.

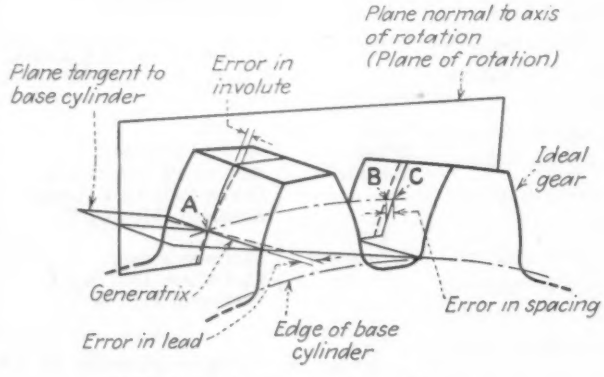
Like any other man-made object a gear must be allowed certain tolerances or departures from the ideal. Manufacturers are often confronted by more or less arbitrarily adopted tolerances listed under the headings of pitch-line runout, maximum spacing error, maximum involute error, maximum lead error, etc. The significance of various tolerances in relation to the gear's ability to transmit uniform rotary motion is more easily visualized through the conception of the ideal gear. Since almost without exception modern spur gears are based on the involute system, only involute spur gears will be considered.

The Ideal Gear

In order to analyze spur gear errors an imaginary gear which has no errors at all is used for reference. This ideal gear is assumed to be any involute gear with any fixed amount of modification that the designer may specify in order to transmit uniform rotary motion under load. It should be emphasized that modifications cannot be considered as errors but variations from a true or a modified form are errors whether within tolerances or not. Thus a heavily loaded pinion which has been designed with a profile that is 0.0003 in. above the true involute at the tip of the gear and 0.0000 in. above the involute at the lowest point of contact (in order to allow for deflections in operation) would be considered in this case as an ideal gear if no other variations were involved. But with a tolerance of + or — 0.0002 in. on profile, a pinion having 0.0005 in. "kick-up" to the tip would depart from the ideal gear by 0.0002 in. and would be 0.0002 in. in error.

In referring the ideal gear to an actual gear the outside diameter, root diameter, fillet radius, chamfer, and mean tooth thickness are adjusted on the ideal gear to equal those of the actual gear. Variations in these dimensions if within tolerances specified by the designer should not materially affect the action of the gear. If the design permits involute or fillet interference and thus prevents the transmission of uniform rotary motion to or from the mating gear, then an ideal gear cannot exist and further investigation into errors is useless until the shortcomings of the design have been removed. Having established a reference point in the form of an ideal gear we now can look at the general classification of spur gear errors.

Error in profile, error in spacing and error in lead are three fundamental types of errors which if integrated will completely describe deviations of the actual gear from the ideal gear. Fig. 1 shows the three fundamental errors. As the errors may vary at various points on the tooth surface, elements of which the surface is made up must be determined.



NOTE: Dotted lines show intersections of planes with non-ideal gears

FIG. 1—The deviations illustrate the variations of the actual gear when compared with the ideal gear.

The profile element is the intersection of the tooth surface with a plane normal to the axis of rotation, or as it is sometimes called the plane of rotation. By rotating the ideal gear around its axis the ideal profile element and the actual profile element in the same plane can be made to intersect at one or more points. With reference to one of the points of intersection, the error in profile at any other point on the profile element of the actual gear is equal to the normal distance to the profile element of the ideal gear. In Fig. 2 the involute

Spur Gears . . .

By SIDNEY CORNELL
Gear Engineer, Pratt & Whitney Aircraft Division, United Aircraft Corp.

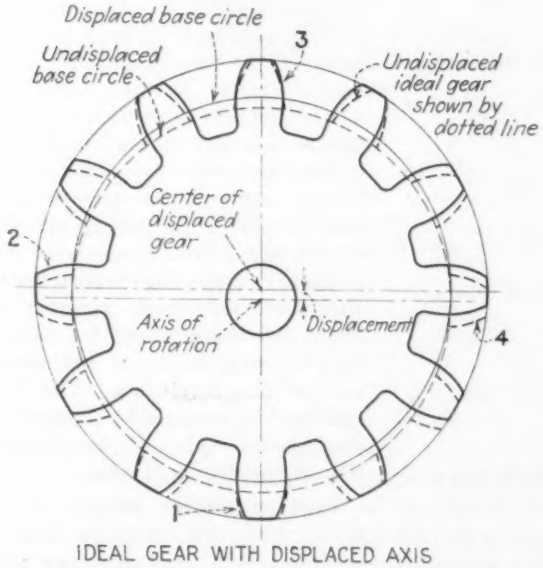
. . . In order to set up measuring standards for spur gears, the author presents a picture of an ideal gear which has no errors and using this imaginary gear as a reference point he skillfully presents a general classication of spur gear errors and outlines a method of recording and evaluating the deviations.

chart shows the involute errors on four different profile elements. Any horizontal line represents a profile element of the ideal involute gear in different rotative positions. The heavier slanting lines represent the profile elements of the actual gear. Thus the top horizontal line represents a profile element of an ideal gear that has been rotated to intersect the profile element of tooth No. 1 of the actual gear at the base circle. According to the scale on the chart the profile elements of the actual gear at the tip of the gear is about 0.0018 in. below the profile of the ideal gear. The error at the tip can be written as —0.0018 in. with respect to the base circle.

Error in profile can be caused by the general displacement of the ideal profile. Thus a geometrically perfect involute profile element when displaced radially or tipped in any direction with respect to a tangent line to the axis of rotation will be in error because it cannot be made to coincide with the profile element of the undisplaced ideal gear. In Fig. 2 profile No. 1 shows an example of radial displacement of the ideal profile.

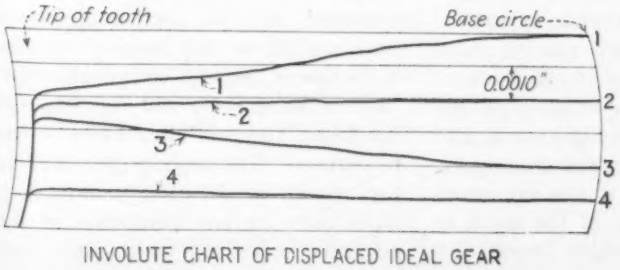
Another type of error in profile is a distortion from the ideal which may be caused by an error in base circle. If the base circle of the actual gear is larger than that of the ideal gear, it will show a *strong* involute with respect to the ideal gear. If the base circle of the actual gear is smaller than that of the ideal gear then a *weak* involute will result. In either case the error will not vary from tooth to tooth around the gear unless other sources of error are present. The departure of the actual profile from any point on the ideal profile with reference to the base circle is very nearly equal to the error in base circle radius per unit of ideal base circle radius, times the distance from the point on the ideal gear to the base circle along a line tangent to the base circle. The horizontal element of the surface shown in Fig. 1 is the intersection of the tooth surface and a plane tangent to the base cylinder of the ideal gear and is called the generatrix. The generatrix of the true involute spur gear is a straight line parallel to the axis of rotation. The ideal gear may be modified to compensate for deflection under load so that the tooth has a *lead*. The generatrix will then not be parallel to the axis of rotation but will still be in the plane tangent to the base circle. If the tooth of the ideal gear is *crowned* the generatrix will be curved.

As in the case of the error in profile, the ideal gear can be rotated around its axis until the ideal generatrix and the actual generatrix intersect. With reference to one of the points of intersection (usually taken at either of the outer faces of the gear) the error in lead at any other point on the generatrix of the actual gear is equal to the shortest distance to the generatrix of the ideal gear in the plane of rotation. Error in spacing occurs when corresponding points on the profile elements of consecutive teeth of the actual gear are not spaced as on the ideal gear. By corresponding points is meant points which are the same distance from the axis of rotation in the same plane of rotation. This is illustrated in Fig. 1. Points *A*, *B*, and *C* are corresponding points on either the actual



IDEAL GEAR WITH DISPLACED AXIS

FIG. 2 — Displacement of geometric axis which results in the irregular transmission of rotary motion. The deviation of four different profile elements is also recorded.



INVOLUTE CHART OF DISPLACED IDEAL GEAR

gear, the ideal gear, or both as they lie on an arc swung from the axis of rotation in the plane of rotation. The ideal gear has been rotated about its axis so that the points in question on the first actual tooth and the first ideal tooth coincide at A. The distance along the arc from B on the second actual tooth to point C on the second ideal tooth is a measure of the error in spacing.

There are basically four different ways of recording errors in spacing. Any of the four ways may involve either the linear or angular measurements of arcs, such as arc BC, but the linear measurements are by far the most common. The four ways of recording the errors may be called for convenience the absolute spacing error, the true circular pitch error, the relative circular pitch error, and tooth to tooth jump. If in Fig. 1 a third actual tooth with intersection D and a third ideal tooth with intersection E on the same arc as A, B, and C are visualized, then arc lengths BC and DE are the absolute circular pitch errors on the second and third teeth respectively with reference to point A. The absolute errors on the remaining teeth may be found in the same way. Any convenient point may be used for reference and the absolute error recorded with respect to that point. To find the true circular pitch error the difference in length of arcs AB, BD, etc., and the true circular pitch (arc AC) is determined. Thus arc BC is a true circular pitch error but arc DE is not. If B and E were coincident, then arc DE would be the true circular pitch error on the third tooth. The relative circular pitch error is determined in the same way as the true circular pitch error except that the arcs AB, BC, etc., are compared with an arbitrarily chosen arc, such as arc AB. The tooth to tooth jump is the variation in either the true or relative circular pitch from tooth to tooth.

The relation between these four different ways of recording errors in spacing and their significance can best be expressed algebraically as follows:

N = Number of teeth in the gear

n = Number of tooth in question with respect to arbitrarily chosen reference tooth (No. 1, No. 2, etc.)

ΔS_n = Absolute spacing error n teeth from reference tooth

ΔCP_n = True circular pitch error at tooth n

$\Delta Rel.\ CP_n$ = Relative circular pitch error at tooth n

J_n = Tooth-to-tooth jump at tooth n

ΔT = Time for ideal gear to turn through one true circular pitch arc

S_n = Distance along arc of measurement from reference tooth to tooth n

V_n = Mean linear velocity of gear along measurement arc when tooth n is in engagement

a_n = Mean linear acceleration of gear along measurement arc when tooth n is in engagement

CP = Circular pitch of ideal gear at arc of measurement and equal to the circumference of measurement circle divided by N

1. $\Delta S_n = S_n - n \cdot CP$ (definition)

2. $\Delta CP_n = \Delta S_n - \Delta S_{(n-1)}$ (definition and 1)

3. $\Sigma_o^N (\Delta CP + CP)$ = circumference of measurement circle (from definition of CP and ΔCP)

$\Sigma_o^N (CP)$ = circumference of measurement circle (from definition of CP)

$\therefore \Sigma_o^N \Delta CP = O$ (subtraction)

4. $\Delta\ Rel.\ CP_n = \Delta CP_n +$ Constant (definition and 1 and 2)

$$\text{Constant} = \Sigma_o^N \Delta Rel.\ CP/N \quad \ldots\ldots (3)$$

5. $J_n = \Delta CP_n - \Delta CP_{(n-1)}$ (definition)

6. $J_n = \Delta\ Rel.\ CP_n - \Delta\ Rel.\ CP_{(n-1)}$ $\ldots\ldots\ldots$ (4 and 5)

7. Distance $S_n = \Delta S_n + n \cdot CP$ (1)

8. Velocity $V_n = \dfrac{S_n - S_{(n-1)}}{\Delta T}$ (rate of change of distance)

$$= \frac{CP}{\Delta T} + \frac{(\Delta S_n - \Delta S_{(n-1)}}{\Delta T} \quad (7)$$

$$= \frac{CP}{\Delta T} + \frac{\Delta CP_n}{\Delta T} \quad (2)$$

9. Acceleration $a_n = \dfrac{V_n - V_{(n-1)}}{\Delta T}$ (rate of change of velocity)

$$= \frac{\Delta CP_n - \Delta CP_{(n-1)}}{\Delta T^2} \quad (8)$$

$$= \frac{J_n}{\Delta T^2} \quad (5)$$

It can be seen from the above that the position of the tooth profiles of the actual gear is measured by the absolute error, the velocity transmitted to or from the gear is related to the circular pitch error, and the acceleration is a function of the tooth to tooth jump. These conclusions are based on average conditions only and are arrived at through the assumption that profile and lead errors are small. The maximum value of the tooth to tooth jump is of major importance because it is directly related to the maximum average acceleration and, therefore, the maximum loads on the gear and its mate as well as the mechanism to which they are connected. The maximum (or minimum) value of the true circular pitch error is also important because smoothness of engagement is markedly affected by errors of this type. Impact loads not detected through the average values shown by the tooth to tooth jump can be controlled by controlling the true circular pitch error. Values of the absolute spacing error, while of major importance in connection with involute splines, are of secondary importance in regard to involute spur gears.

In a given gear any combination of profile, spacing and lead errors may exist and the values may vary around the gear and across the face of the teeth. In many instances the variation in the errors follows a definite pattern. These patterns will be found to be characteristic of the displaced ideal gear, the general distortion of the ideal gear, the local distortion of the ideal gear, or any combination of the three.

Displacement of Ideal Gear

The most simple pattern and one that is frequently encountered is the high quality gear which is geometrically the same as the ideal gear except that the axis of rotation has been displaced parallel to the geometric axis. This type of displacement is shown in Fig. 2. Irregular transmission of rotary motion to the mating gear is the result, because the involute system permits variation in center distance without affecting conjugate action, full tooth bearing will still be had with this type of error. If the profile of the gear is checked with respect to its axis of rotation it will be found to vary as shown on the involute chart in Fig. 2. Also the tooth spacing error (true circular pitch error and tooth to tooth jump) will vary through maximum and minimum once in one revolution. The mating gear will go through an acceleration—deceleration cycle once in one revolution of the displaced gear.

Another similar pattern of error occurs when an otherwise ideal gear is tipped with respect to the axis of rotation. A plane section of such a gear normal to the axis of rotation will show a general elliptical shape. Tooth spacing error will vary through maximum and minimum twice in one revolution. The mating gear will go through an acceleration—deceleration cycle twice in one revolution of the displaced gear and will also show

a minor acceleration — deceleration phase as each tooth meshes due to the non-conjugate action of the tipped involute. A full tooth bearing cannot be expected and the bearing will move from one edge to the other as the gear rotates. Involute displacement and therefore involute error will

be found to vary across the face width of any given tooth. This error will be super-imposed on the error caused by the tipping of the involute. Spacing error will also be affected by position on the tooth face. Error in lead is introduced by the tipped axis and will vary in the same way as the spacing error.

General Distortion of Ideal Gear

Another class of errors frequently encountered is found in the general distortion of the ideal gear. The elliptical type of distortion may occur from heat treating or from the machining of the gear. When this type of distortion occurs, the effect is similar to that of the tipped ideal gear except that the bearing does not wander back and forth on the face. Conjugate action may still be had in some form of elliptical distortion if the gear is generated under certain conditions. In cases where one end of a gear is distorted to an elliptical shape and the other end remains circular a variable error in lead will be found. In addition to the elliptical type of distortion there are, of course, any number of possibilities of irregular distortion producing any number of acceleration and deceleration cycles per revolution of the gear.

The local distortion of the ideal gear may be either repetitive or random. For instance an otherwise ideal gear may have one tooth displaced causing a random error in spacing. A gear cut with an incorrectly sharpened hob may have a repetitive error in involute. A distortion in lead alone sometimes occurs and is usually uniform around the gear if it is the result of generating. This type of error affects the profile in the plane of rotation if the error occurs in generating the teeth, but the effect is negligible even with wide tolerances in lead. Uniform error in lead will therefore not affect the gear action but will tend to produce an edge bearing. Uniform error in lead could also be classified as a general distortion of the ideal gear as it could be visualized as the general twisting of the ideal gear around its axis.

In actual practice combinations of two or more classes of errors are often found. A gear may be found with a displaced axis of rotation plus an elliptical distortion. A gear tipped with respect to the axis of rotation may have random indexing errors. Acceleration and deceleration patterns will be a summation of the patterns of the two types of distortion.

Measurement of Errors

There are three fundamental methods of determining the overall quality of spur gears namely the direct measurement method, the functional method and a third method which can best be described as a double-sided method. Practically all of the many machines and fixtures on the market today for measuring gear quality fall into one of the above classifications. In tooling for quality control, it is helpful to keep in mind these three general methods in order to insure complete control.

FIG. 3 — Involute measuring machine with electrical recording device.

o o o

RIGHT

FIG. 4—The spacing checker measures the relative circular pitch error and tooth-to-tooth jump.

o o o

Direct Measurement Method

The direct measurement methods cover the actual measurement of involute profile, spacing and lead. As full integration of these measurements is seldom practical representative measurements are usually relied upon. The involute profile is usually measured mechanically with a pointer contacting the profile and by any of various mechanical means made to move over it following a true involute path. Fig. 3 shows one of these machines with the pointer in contact with the gear tooth profile. The deviation from the true path by the actual

profile is registered on a dial indicator or automatically recorded on charting paper. One of these automatically recorded charts is shown in Fig. 2. By using the involute measuring machine, the error in the actual profile element can be determined.

The involute profile can also be measured with an optical comparator if the face width of the gear is not too great, and if there are no shoulders on the gear blank which would interfere with the passage of the light. In this method the magnified shadow of the profile element at the inner or outer face of the gear profile is cast on a screen and compared with a layout of the ideal profile made to the same scale as the magnification. While this optical method has been found to be excellent for measuring tooth thickness, root radius, and other dimensions, it is not in general use for checking involute profile principally because the concentration required to observe variations in tenths even with large magnifications would be too fatiguing for general quality control.

The principle of the involute as a constant rise cam is sometimes used in measuring profile. The gear is turned through arbitrarily selected angular increments by means of a precision dividing head. The amount of rise of the involute of the ideal gear is computed for each angular increment and the actual rise of the involute of the actual gear is measured with a surface gage and indicator and compared with the computed figures. This method is rather slow but has been used with success on master gears.

The absolute spacing error can also be measured with a precision dividing head with which the angular displacement of each ideal gear tooth can be controlled and the amount the actual tooth is out of position can be measured with an indicator. This is a relatively slow method and is seldom used for production work. A more rapid method around which several machines on the market have been designed consists of comparing the distances between two points identically located on successive teeth with similar measurements all around the gear. In other words, this type of machine measures the relative circular pitch error in spacing around the gear. The tooth to tooth jump may also be read directly. One of these machines is shown in Fig. 4. Some of these machines can also be adjusted to measure relative normal circular pitch or base pitch. This means that they compare the variation in spacing from one tooth to the next along the line of action. This latter type of measurement gives a combination of errors in relative circular pitch and involute. The odontometer is a portable instrument which also measures relative base pitch errors and which can be applied directly to a gear in the process of manufacture. By comparing normal circular pitch readings on the gear in question with normal circular pitch readings on a master gear, involute errors as well as spacing errors can be detected.

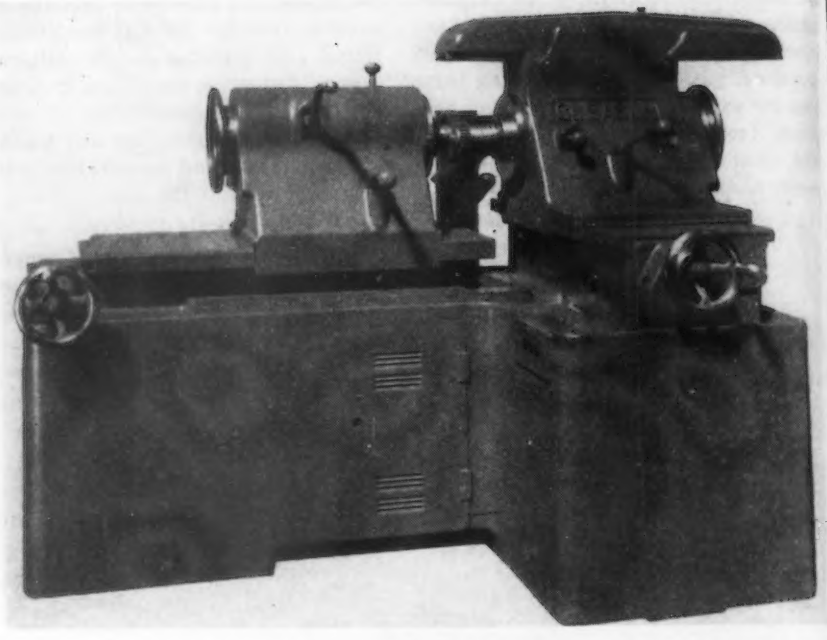

Fig. 5—Spur gear testing machine sometimes called "power tester."

Frequently tooth spacing is checked between non-consecutive teeth. The significance of this type of check is not as great as it may seem since direct measurement of the variation in spacing between adjacent teeth will indicate completely the quality of the spacing. Since the tooth action is from one tooth to its neighbor, the relation between one tooth and a tooth three teeth away has only indirect effect on the action of the gear and its mate.

The last fundamental type of gear tooth error is the error in lead. On a spur gear the simplest type of machine can be used for measuring this type of error. Lead checkers are on the market designed to handle helical gears and, of course, can be used on spur gears since a spur gear is nothing more than a helical gear with a zero degree helix angle. However, if spur gears only are to be handled, the gear can be mounted on centers and an indicator finger in contact with the tooth surface can be moved back and forth on a slide running parallel to the centers. Such a device constitutes a simple spur gear lead checking fixture. Another even simpler but less speedy method is to mount the gear on bench centers which have a wide enough bed, scraped parallel to the line of centers, so that a surface gage with an indicator can be placed to measure the maximum height of the involute in an above center position at each end of the tooth.

Functional Methods

A common functional method in inspecting gears is to run the gear with its mate (especially if the gears are to be kept in sets) or with a master gear which will duplicate the action of the mating gear. Several machines are on the market for running a pair of spur gears together under simulated operating conditions. These machines, an example of which is shown in Fig. 5, are sometimes called "power testers." Experienced operators can determine a good deal about the quality of the gears by their sound, but a more thorough method often supplemented by sound testing is to coat one or both gears with red or blue lead, or a similar compound, and to examine the *bearing* produced after the gears have been run under a pre-determined amount of load at the correct center distance. The thickness of the lead coating, the speed, brake pressure and the length of time the gears are run together will have a considerable effect on the appearance of the bearing. Consequently this type of inspection should be carried

out by an experienced operator and in conjunction with occasional checks of profile, lead and spacing. The marked advantage of this method is that the overall quality of the gear can be quickly determined. Lead and involute errors are easily detected. Spacing error especially of a progressive nature is not so noticeable from the bearing but can be often determined from the sound.

Another functional method or near functional occasionally used by "old timers" is to mount the gear and master on parallel arbors at standard center distance. The gears are then spun by hand and a slight drag applied to one to keep the driving sides in contact. The vibration felt by the finger tips on one of the arbors is then roughly interpreted as a function of gear errors.

Double-Sided Methods

Double-sided methods of measuring the quality of spur gears are methods in which the indications of error are determined solely by the relation between the errors on the *drive* side and the errors on the *coast* side of the teeth. As the *drive* and *coast* sides of the gear teeth may have independent errors, it is possible for the errors of one side to cancel or augment the errors of the other side when the two are inspected simultaneously with any of the double-sided methods. Because of this it is difficult or impossible to accurately determine the values of fundamental errors with any of the double-sided methods, but owing to their speed and simplicity such methods are extensively used and for certain types of quality control definitely workable.

There are two general types of double-sided inspection methods for spur gears. The first type consists of running the gear to be inspected with a master gear with center to center pressure to keep the gears tightly meshed. This method is not truly a functional method although it is sometimes referred to as such. It does not approximate actual operating conditions in regard to rotative speeds or tooth loading, and it operates with both sides of the teeth in action. In actual practice spur gears operate on only one side of the teeth at a time (except in certain unusual no-backlash installations).

The tooth thickness of the master gear is usually *built up* so that when tightly meshed with the gear to be inspected, the design center distance will be approximately maintained. If this is not done bottoming of the gears may occur or false indications of fillet interference or involute interference may appear. Devices for this type of double-sided inspection are known as hand-rolling fixtures or machines and consist of two arbors the distance between which can be varied with slight pressure. The variation in the distance between the arbors when the tightly meshed gear and master are rolled around together by hand is recorded on a dial indicator. Errors which decrease the tooth space will increase the center distance and vice versa. The flickering of the indicator needle as the gears are rolled together indicates the presence of local spacing errors or profile errors. General distortion of the ideal gear will sometimes be recorded in the full reading of the indicator. The Fellows Red Liner also employs the principle of the tightly meshed master gear and adds the feature of automatically recording the center distance variation. In this way a better picture of local errors can be obtained as momentary changes in center distance make definite indications on a chart which would appear only as the flicker of the indicator on a hand rolling-fixture.

The overall movement of the indicator on the hand-rolling fixture is sometimes referred to as *pitch-line runout*. This is a convenient term but because double-sided methods emphasize or minimize errors in action, and because of other kinematic reasons, the runout thus measured is not the true indication of pitch-line distortion. For instance in the generated type of elliptical distortion of the ideal gear, it is possible for the tightly meshed master gear to be accelerated and decelerated with respect to the gear being tested without any change in center distance, and thus show no indication of the error. Elliptical distortion of an ideal gear that has been sprung *out of round* will show an exaggerated variation in center distance with the master out of proportion with the acceleration and deceleration that would be imparted to its mate.

The second type of double-sided inspection is a method which does not attempt to measure profile errors. It consists of measuring *pitch-line runout* with a pin, ball, cone, rack tooth, or rack space. The same objections hold true for this type as for the master gear type of double-sided inspection. The virtues of the two types differ in that the first type is one of

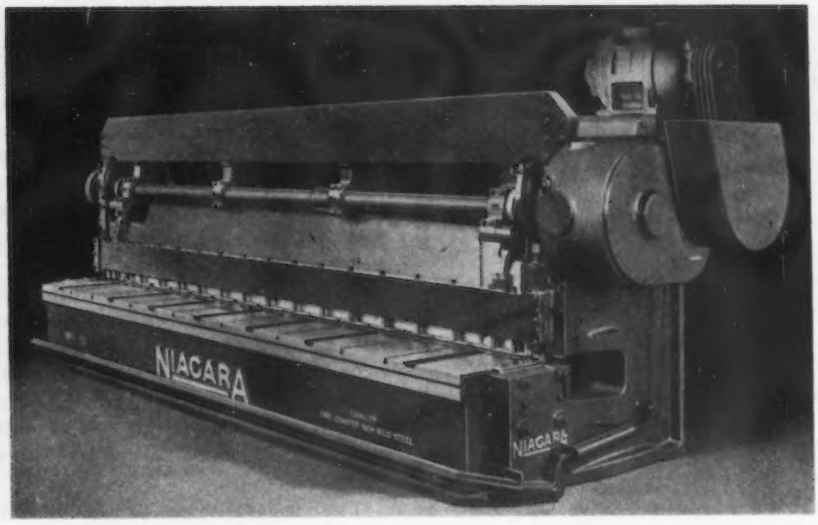
New Equipment . . .

Presses

. . . Description of new developments in hydraulic and hand presses and related sheet metal machinery is continued in the following pages from last week's issue.

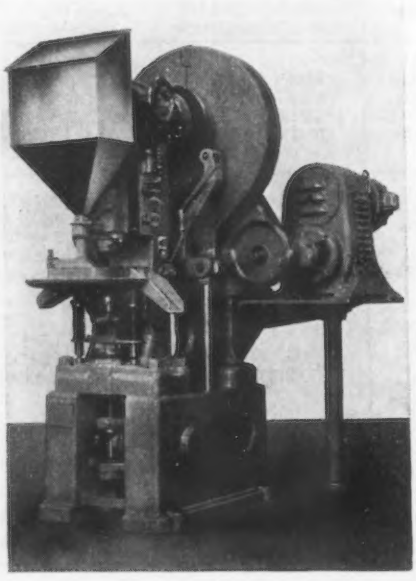


Squaring Shear

A NEW long-length power squaring shear has been added to the Series L line made by the *Niagara Machine & Tool Works*, Buffalo. This shear has a cutting length of 20 ft. and, by utilizing the gap in the housings, even longer sheets can be squared, trimmed and split. The massive bed and housings together with triangular section crosshead maintain straightness and correct clearance of knives throughout the cutting length. Convenient operation and quick gaging speed up handling of stock and reduce operators' fatigue. Self-measuring, ball bearing, parallel back gage measures in increments of 1/128 in. Full visibility of cutting line facilitates cutting to a scribed line. Drive mechanism operates on anti-friction bearings and is completely enclosed in an oil-tight case.

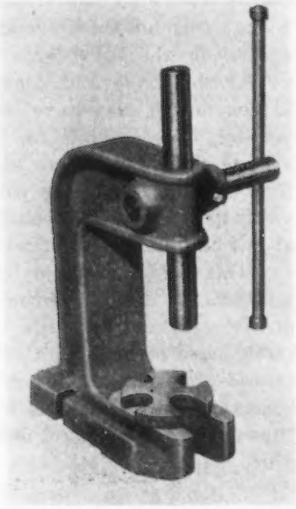
Automatic Powder Press

AN improved model of automatic press for production of powdered metal parts and Steatite and other dry-mix ceramics in which accuracy in dimension and exacting control of density are primary requisites has been brought out by the *F. J. Stokes Machine Co.*, Tabor Road, Olney P.O., Philadelphia. Pieces up to 3 in. diameter with a die-fill of 2⅝ in. are compressed by this machine at rates of 15 to 45 per min. at pressures up to 20 tons. Pressure adjustments may be made while the press is operating, assuring uniform density. Either the desired porosity in oil-impregnated bearings or the extreme density necessary in a hard carbide tool bit is readily obtainable, it is claimed.



Hand Arbor Presses

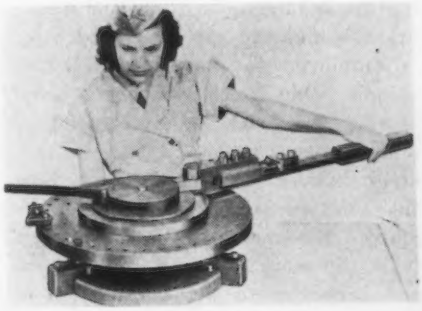
NEW 2 and 3-ton bench type arbor presses have been put on the market by *Lempco Products, Inc.*, 5682 Dunham Road, Bedford, Ohio. Snap ball check permits ram to be spun down to work. Heavy wrought steel pressing block is notched with 1⅛, 1⅞ and 2 in. openings. Large



machined table surface provides ample opening and support, taking work up to 14 in. diameter. It is claimed to be efficient for assembling, disassembling, bending, straightening and all kinds of operations requiring up to 3 tons pressure, and is made in both bench and wall types.

Pipe Bender

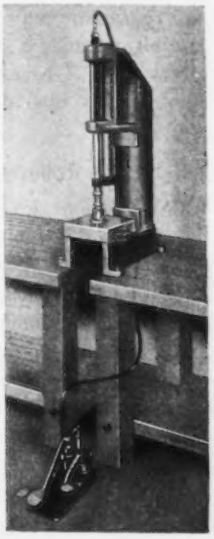
THE Di-Acro Bender No. 3 has been produced by *O'Neil-Irwin Mfg. Co.*, 317 Eighth Avenue, South, Minneapolis 15, especially for aircraft and marine work. Incorporating all the features of the smaller models, the new unit is more rugged throughout and has a considerably greater radius forming capacity. A 7-in. circle and two right angle bends can be obtained in one operation. Although especially useful in forming aircraft tubing, the



unit is capable of forming a ½ in. cold rolled steel bar to a 1 in. radius or larger. Operating leverage is 35 in. and may be increased up to 80 in.

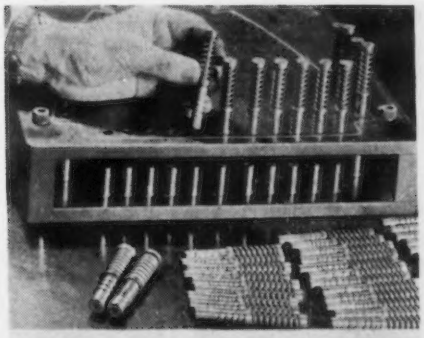
Hydraulic Arbor Press

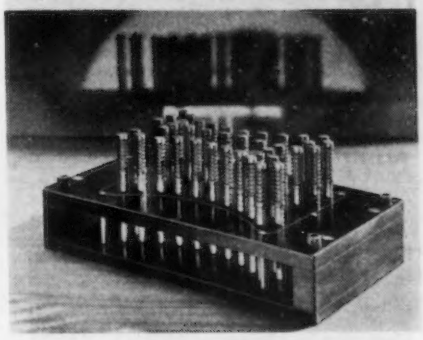
A COMPLETELY new Speedpress, a hydraulic arbor press, has just been announced by *Studebaker Machine Co.*, 9 South Clinton Street, Chicago, Ill. It is foot-controlled, leaving the operator's hands wholly free for the work. Pressures from zero to 20,000 lb. are obtained by pedal of hydraulic control base, connected with press by steel tube. One movement of the applicator pedal and the ram moves downward to contact with the work. Another foot pressure on the booster pedal, and any holding grip desired up to 20,000 lb. is applied. A release pedal breaks the pressure, and the ram automatically returns to the top of its travel.



Punch Plate System

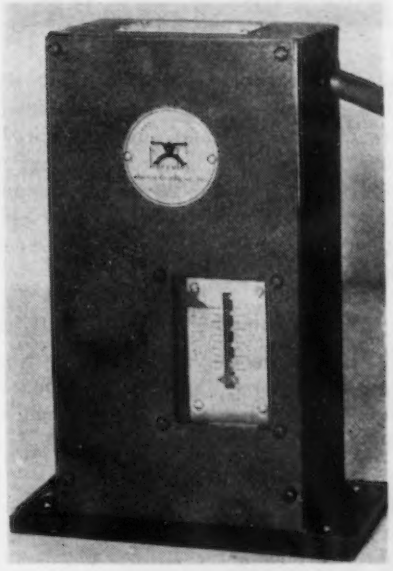
NEW equipment for punching holes arranged in any desired pattern in sheet material up to 43 x 45 in. in size has been brought out by *Wales-Strippit Corp.*, 345 Payne Avenue, North Tonawanda, N. Y. The plate set system uses Walesite plate sets and PS punch assemblies and dies to form self-contained punching units that are ready for use as soon as they are placed in the press. Being interchangeable, changing from one punching job to another is easily accomplished. A master template for locating the punch centers on the top plate of the set is provided. Two plates of Walesite are separated by spacer bars and are held together rigidly by bolts and dowel pins. The sets are made in 48 sizes.





Pressure Switch

A NEW type of electrical pressure switch with pressure ranges from 5 to 5000 lb. has been developed by *Hercules Electric & Mfg. Co.*, 2416 Atlantic Avenue, Brooklyn 33. It is equipped with a direct action gage for hydraulic pressures operating a very sensitive electrical switch. The overall dimensions are approximately 10 x 7 x 3 in.



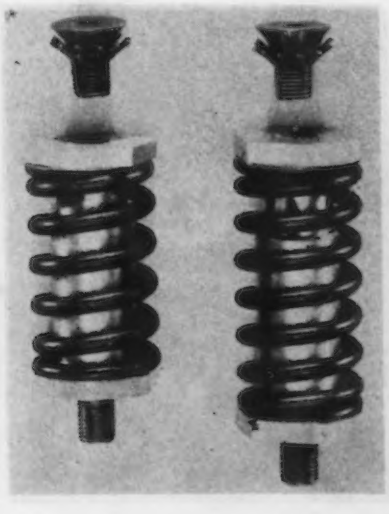
Wire Reel

A POWER-OPERATED wire reel to replace manually loaded ones has been produced by the *F. J. Littell Machine Co.*, 4151 Ravenswood Avenue, Chicago, especially for women operators. A drop center and motor drive on the Powertilt does the hard work of elevating the coil from the floor up to the working level automatically. The drop center permits the operator to roll the coil upon the floor and simply tip it onto the reel

core. A slight push against the coil centers it and the drop center is locked by throwing over a U-shaped bar. The reel will handle coils up to 25 lb.

Spring Stripping Units

SPRING stripping units called Strippits, which allow the removal and replacement of the stripper plate or dulled or broken punches without taking the die out of the press or disturbing any part of the setup, have been announced by *Wales-Strippit Corp.*, North Tonawanda, New York. The use of thinner, easier-to-handle, less expensive stripper plate is possible because pressure is exerted on the plate only when the die is punching, it is said. No stripper plate is required for stripping scrap from die. The built-in spring is held compressed by a retainer and assembly link.

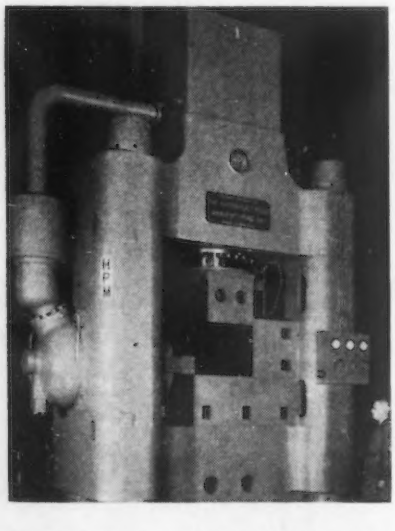


Inclinable Press

THE 150-ton C36½ press has been added to the line of open-back inclinable presses made by the *Ferracute Machine Co.*, Bridgeton, N. J. It is of the geared type with jaw clutch but can be had with pneumatic friction clutch and brake. The press frame casting is of steel, which reduces the weight of the press and the floor space required without sacrificing strength and rigidity. The stroke ranges from 6 to 13 in. Bed measures 32 in. front to back by 50 in. right to left. The entire series comprises 15 sizes ranging from 1¼ to 7 in. diameter shaft. They can be had in various combinations of special features that permit them to operate fully automatic, with finger tip controls.

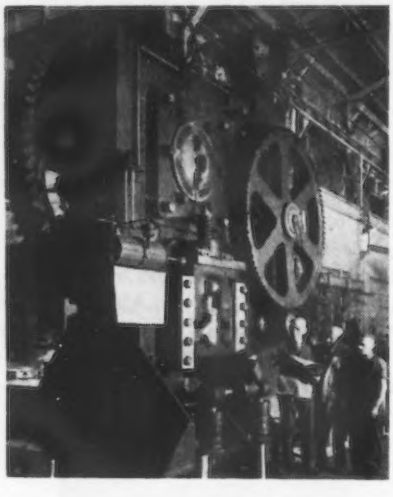
Powder Metallurgy Press

THE completion of one of the largest hydraulic presses ever built for briquetting powdered carbides of tungsten, titanium or tantulum for carbide cutting tools, dies and inspection gages is announced by the *Hydraulic Press Mfg. Co.*, Mount Gilead, Ohio. The press is also suited to other powdered metal forming which requires the application of high pressure from two different points. It will exert a 1500-ton downward acting force and a 1000-ton horizontal acting force. It is completely self-contained, being equipped with two H-P-M Hydro-Power radial hydraulic pumps which generate the operating pressure.



Billet Shear

DESIGNED and built by *Buffalo Forge Co.*, Buffalo, the No. 17 billet shear is believed to be the largest machine of its type ever constructed. Weighing over 80 tons, the machine has an electrically welded "Armor-Plate" frame. Pressure on the knives is 4,500,000 lb., cutting



10-in. steel bars at the rate of six cuts per min. Clutch and hold-down are air operated and automatic pressure lubrication is provided by a lubricator mounted on the machine. The whole unit is operated by a 125 hp. motor which drives the flywheel through multiple V-belts.

Spinning Lathe

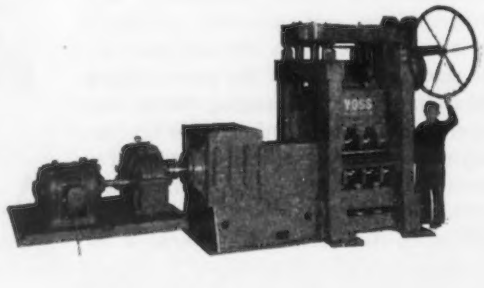
THE Ferracute spinning lathe No. 224, offered by the *Ferracute Machine Co.*, Bridgeton, N. J., has a two-speed motor which permits adjustment between 200 and 1000 rpm. The speed can be varied while the lathe is running. The motor is started and the transmission is set at the desired working speed before the headstock spindle is started. A control lever engages a dry-disk clutch, bringing the spindle up to speed and a cone brake brings the spindle to rest. Air is employed to move the tailstock spindle. One directional control lever, located for right-hand control, is moved toward the work, and the tailstock spindle travels forward. Further movement locks the spindle in place. Movement of the lever away from the work unclamps the spindle and causes it to withdraw. Use of tapered headstock spindle with a corresponding taper in the faceplate offers true-center mounting. The two members are keyed and held in place by a spanner nut, providing for quick removal of the faceplate.

Hydraulic Fittings

A LINE of high pressure hydraulic fittings is announced by the *Anker-Holth Mfg. Co.*, 332 South Michigan Avenue, Chicago 4. Standard assemblies for working pressures up to 3000 lb. include a check valve which is reversible by placing the steel ball ahead of the spring; a safety valve, which is spring loaded and adjustable; a straight connection; elbow and T-assemblies and ⅜ and ¼ in 4-way operating valves.

Roller Leveler

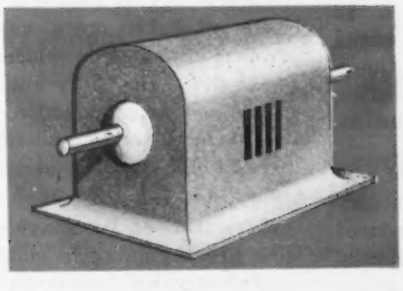
TWO roller leveler machines built to handle armor plate have been completed by *Voss Machinery Co.*, 2888 West Liberty Avenue, Pittsburgh. The machine pictured can take care of ¾ in. armor plate in continuous sheets, and up to 1 in. in some other steels. It can also be designed and built for much heavier and wider plates. Similar to the other roller levelers manufactured by the company, the straightener is of heavier construction and incorporates improvements in design. An armor plate leveler, said to be the largest and heaviest of its type ever built, has been completed by the company. The new big leveler has all the features of the former machines and is regarded as the forerunner of more heavy and powerful levelers.



PARTS FOR FACTORY EQUIPMENT & MACHINERY

Advances in engineering and design and improved materials will make "The work shop of the world" a new vision of utilitarian beauty.

Pressed Metal Parts and stampings will be used for factory equipment and machinery in the future, just as they have been in the past, but to an accelerated degree. They will make possible revolutionary advances, due to their ability to stand up to abuse, resistance to shock, rugged strength, ability to withstand corrosive conditions, survive radical temperature changes, not to mention low cost and a score of other characteristics, providing requirements not met by any other material.



Sound safe designs literally demand fullest possible use of stampings. Call on the Parish Pressed Steel Company for engineering cooperation. Our services will be found helpful.

Assembly Line . . . STANLEY H. BRAMS

• Goodyear's Jackson tire plant reconversion offers a previewing of the picture ahead . . . Truck tire needs throw long shadow over plans for 1944 production of civilian vehicles.

DETROIT—A prototype for reconversion is at hand in the Jackson, Mich., plant of the Goodyear Tire & Rubber Co. This plant was a prime prewar producer of original equipment tires sold by Goodyear; when war came on it converted to output of 3-in. guns and fuel cells. Now it is reconverting to manufacture of tires. The use of the tires is mainly for military and essential commercial wheels, but the move is definitely a reconversion, and as such previews some of the problems of the future.

In this particular case, physical reconversion costs were not a factor. Government contract provision for rehabilitation expense is caring for re-installation of machines, etc., and all old equipment was put back into use. In addition, Goodyear is investing around $4,000,000 in new equipment, which should logically be charged to expansion rather than reconversion, for the Jackson Goodyear plant was built in 1937, was up to the minute, and had few worn-out or obsolete facilities.

The effect of reconversion on the workers is interesting. Payrolls had swollen to almost triple their former size at the peak of the war production program, gaining to 2300 men and women. Today they stand at about 675, and will reach no more than 1000 when the reconversion and expansion is completed.

The bulk of the increased payroll was secured from the Jackson area population. A comparatively small number of men from other areas, particularly the rather thinly war converted western Michigan section, took over machining operations of major complications; operators for the other machines were trained among local workers. Substantial numbers of women were hired.

The in-migrants, for the most part, have already left Jackson. Most have gone to other industrial centers—Detroit has attracted a large proportion. This is extremely interesting if it portends a general development that migrant war workers will leave the areas to which they flocked.

Not typical in forthcoming broad reconversion is the situation of the workers now laid off. Increases in subcontracts at Reynolds Spring Co. and other Jackson plants made jobs for most of these, and they switched. Those since called back to work at the Goodyear plant have returned readily, to protect seniority.

ONE problem at Goodyear which will be general when national reconversion starts has been the matter of pay rates. As rubber workers, the Goodyear employee pay scales were lower than the rates paid them for machine operations. Going back to their original jobs, they are grumbling about the concurrent pay reductions. Thus far there has been no adjustment of this situation; WLB is standing on its pay classification lines and gives no indication of changing them.

Mention was made of expanded facilities. A part of this lies in a new building which Goodyear is putting up. Its cost runs around $1 to $2 more per square foot than would have been expected in prewar times. Reconstruction costs within existing plants are above that proportion, however.

From this picture the shape of several reconversion factors can be dimly made out—complaints over reduced pay scales which, although rejected now might become loud enough in national volume to hold postwar wage levels at their present stand, even though the classifications of work are lower; higher costs for physical refurbishing of plants than were required to transform them for war work; less of an in-migrant problem than has been expected. These indications cannot be considered positive, but confirmatory evidence should be watched for.

The Goodyear reconversion calls attention anew to worries over supplies of heavy duty tires, which are now beginning to shape up as a prime bottleneck in the 1944 truck program. Original projections called for upward of 20,000,000 truck tires to be produced this year; since then the indications are that the total will be below 18,000,000. Of these, approximately 5,000,000 were earmarked for original equipment; this total is now down around 3,500,000. Inasmuch as a proportion of about 25 per cent natural crude must be inter-mixed with the synthetic used to make truck tires, in order to withstand the greater operating load placed on the heavier casings, these curtailed figures seem to be maximums. Also imposing a positive limitation on production is the fact that molds for processing heavy tires are quite definitely in limited quantity, and therefore offer a positive check on production.

AS a result, truck tires have gone under an allocations system just as stringent as CMP. There are eight claimant agencies involved. The manufacturers of vehicles for any of these agencies must file their wants in Washington on the first day of the second month in each quarter. Allotments to claimants will come back 15 days later, and in the 30 succeeding days orders must be placed by vehicle manufacturers with suppliers. Schedules are frozen as of the start of the quarter.

To fit the shortages of truck tires, the much-juggled 1944 truck program has been shaken down more than 15 per cent in the Army vehicle category. Of the 742,433 military units originally planned for production this year, 123,149 have been eliminated, including 42,013 medium and 81,136 light trucks.

More facts on the shape of the cutback are beginning to come to light. Jeep production apparently was most severely reduced, curtailments being sent out on the heels of a small increase granted to Willys previously. As was said here earlier, Dodge was substantially sliced, and the entire half-track program, participated in by White Diamond T and Autocar, was all but eliminated. There were reductions among the very small truck makers as well as these large ones.

In theory at least, the military cutbacks make possible the increase of

You get more than a fine tap WHEN YOU SPECIFY "GREENFIELD"

THE phone rings. "We're having trouble with our tapping operation. Can you send a man?"

"Greenfield" can . . . and does. Because "Greenfield" feels its responsibility is not only to produce fine threading tools, but also to help customers get the most out of them through proper selection and use. Its responsibility ends only when its customers are getting top threading performance. That is one reason why you get more than a fine tap when you specify "Greenfield."

There are "Greenfield" field representatives in Ashville, Atlanta, Boston, Chicago, Cleveland, Dallas, Dayton, Denver, Detroit, Fort Worth, Hartford, Jacksonville, Los Angeles, Milwaukee, Nashville, New Orleans, New York, Philadelphia, Pittsburgh, Portland (Ore.), St. Louis, Salt Lake City, San Francisco, Seattle, Syracuse.

GREENFIELD TAP AND DIE CORPORATION • GREENFIELD, MASS., U.S.A.

civilian truck production by that quantity or more. In fact, however, no such thing will ensue, because of the tire shortages and their superimposition on bottlenecks of bearings, transmissions and axles.

The 15 per cent Army reduction may likely be moved onto the schedules for commercial trucks, but is less likely to be translated into finished production. In fact, the Army cutbacks bring aggregate vehicle production in all categories for 1944 just about to the extreme limit indicated by 3,500,000 available original equipment casings—in other words, around 900,000 vehicles, none equipped with spare tire.

Those who hoped that civilian vehicle production would get off to a good start were cautioned by their more realistic fellows, and the January and February showings bear out the pessimists. As reported here earlier, actual January production of civilian vehicles fell below more than 2000 units. February output was somewhat higher, but it was still farther away from the month's quota than was the case in January.

This all serves to put the truck industry in a rather irritated frame of mind these days, and their composure is not at all aided by the newly announced ODT program for rebuilding motors, transmissions and axles to keep the nation's trucking fleets operating.

ODT reports that it has prevailed on WPB to allocate enough steel to produce 138,000 engines, 18,000 transmissions and 7000 rear axle assemblies. These quantities, theoretically, will be pro-rated among various manufacturing interests and produced as new goods. They will be installed on truck fleets where needed, and the units they replace will be returned to the factories for rebuilding and subsequent distribution in the field.

Truck people have promised to go along with this program, but in private they criticize it as buck passing by ODT. They point out in the first place that the quantities are too small to do much good when spread out over the country among many different manufacturers. They point out, second, that although some of them have facilities for rebuilding motors, as in the prewar days, none has ever had any experience rebuilding transmissions and rear axles. Conceivably the professional motor rebuilders will aid in this latter branch of operations, but establishment of new facilities will likely be necessary in any case, and the difficulties of obtaining new facilities are enough within themselves to cast a shadow over the outlook for this new program.

Great Postwar Prosperity Predicted by George Bacon

• • • **George W. Bacon**, of Ford, Bacon & Davis, Inc., New York, predicted on March 15 that this country will enjoy a postwar era of unprecedented prosperity.

Mr. Bacon, a founder of the company, was the central figure in a celebration, held in its general offices at 39 Broadway, New York, on the company's 50th anniversary. Another founder, George H. Davis, now retired, was present when James F. Towers, president of the firm, presented Mr. Bacon with a commemorative medal on behalf of his associates. The occasion drew many leaders of the industrial, utility and banking worlds.

Ore Shipments to Upper Lake Ports Total 86,413,141 Tons

Cleveland

• • • **Mine shipments** of Lake Superior iron ore for 1943 by railroad to upper lake ports and all-rail to consumers totaled 86,413,141 tons according to the Lake Superior Iron Ore Association, of which 85,962,168 tons came from U. S. ranges and 450,973 tons came from Canada. The U. S. range shipments constituted 99.48 per cent of the total. All-rail shipments direct to consumers located entirely in the upper lake regions totaled 2,016,161 tons, of which 820 tons came from Canadian ranges and 2,015,341 tons came from American ranges.

Beneficiated Superior ores for 1943 totaled 15,904,756 tons. Of this, 15,453,783 tons originated in U. S. ranges and 450,973 tons originated in Canada. Minnesota ores show a slightly higher rate of beneficiation than required of over-all Lake Superior ore shipments. Of total ores shipped from the Minnesota region, the association's report shows that 22.09 per cent were beneficiated. According to the report, 18.40 per cent of all Lake Superior ores shipped in 1943 were beneficiated.

Falck Succeeds Black As Head of Production Group

Washington

• • • **Edward Falck** has been appointed executive director of the Combined Production and Resources Board, succeeding William M. Black who resigned recently. Mr. Falck has been with WPB and its predecessor, OPM, since July, 1941.

Plane Output 350 Per Day In U. S., C. E. Wilson Says

• • • **The aircraft** industry has produced 153,061 planes during the past three years, and present production is at the rate of 350 planes per day, Charles E. Wilson, chairman of the Aircraft Production Board of WPB, said March 14.

The volume and effectiveness of American plane output was pointed out in the following statement by Wilson:

"Against the declining effectiveness of German aerial strength, the production power of the Allies stands in stark contrast. British Production Minister Oliver W. Lyttelton recently told the House of Commons that Britain had produced 90,000 planes through the end of 1943. In three years, the United States aircraft industry has produced 153,061 planes of which 105,126 were combat planes. We have retained over 122,000 of these planes and we have sent approximately 28,000 planes to our Allies. And we are adding to our output of planes at the rate of 350 per day.

C. E. Noyes New Director of OCR Civilian Relations Div.

Washington

• • • **Charles E. Noyes** will succeed Dr. Austin Grimshaw, who recently resigned as director of the Civilian Relations Division of the Office of Civilian Requirements, WPB has announced. Mr. Noyes has been assistant director of the division since last June. Dr. Grimshaw, Cambridge, Mass., educator and business consultant, will assume new duties in the office of the vice-chairman.

Carburs---INDUSTRY'S FIRST CEMENTED-CARBIDE ROTARY FILES

Are Now Products of LINCOLN PARK

LINCOLN PARK
Continues to Produce

- *Carboloy Gages*
- *Chrome Plated Gages —both New and Salvaged*
- *Steel Gages*
- *Small Precision Built-Up Gages*
- *Thread Plug Gages Salvaged by Chrome Plating*
- *Non-Cutting Precision Tools of Carboloy, Chrome Plate or Steel*
- *Carblox Cemented-Carbide Gage Blocks*

During the past year, Carburs have found wide acceptance among the country's leading manufacturers. These tools, the first of their kind ever to be produced, have proved their ability to offer at least fifty times the life of ordinary rotary files.

With the merger of Carbur, Inc. with Lincoln Park Industries, facilities are now available for greater and more varied production of Carburs. The experience gained by the Lincoln Park organization over a period of many years in manufacturing high precision inspection and production equipment now promises even finer quality cemented-carbide rotary files than were possible before.

At the present time, Carburs can be manufactured in shapes and sizes to meet almost any need. We'll be glad to supply you with full information.

Washington . . .

• Government pokes its nose into everything else but lets local draft boards sweat it out alone . . . Either military programs must be slimmed or size of the armed services must be trimmed.

WASHINGTON — The manpower muddle is approaching the place the material situation found itself in early last year. Much talk is heard of shortages, and there are many fancy schemes floating in air, overstatement of labor needs by manufacturers, and general maldistribution.

Then in materials, as now in manpower, individual bad spots caused over emphasis of situation. Officials are privately saying that if military procurement is sliced back to realistic levels, as it was to "cure" the steel shortage, the manpower inflation bubble will be pricked too, and the country will turn up with manpower surpluses.

Either military programs must be slimmed, or armed service size must be trimmed temporarily to manpower supply. Cutbacks and cancellations already are causing unemployment pockets, and the trouble is no agency dealing with manpower has any idea of the effect of breaking prime contracts on subcontracts.

Then there is a lot of bearish talk by the services calculated to swing public opinion in favor of universal draft. Selective Service, WPB and manpower officials are complaining draft boards are deferring men not entitled to be deferred under existing directives, are favoring men with dependents.

ELECTION year politics are seen in the fact that Washington does not call for lists of deferred men and advise boards of the number and kind of improper deferments. The excuse is that it is against the policy of letting local boards be self-governing. Yet the government does not hesitate to poke its nose into all manner and kinds of employer-employee relationships which are of even more local and private character.

Equally inconsistent is the excuse for not giving 4F's limited service, as the President's medical commission opposed, the late combing of governmental and farm deferments. Congressmen have the feeling that government can't be too sincere in its attempts to clean up manpower.

The recent flare up over local boards' "misinterpretation" of the President's order for review of deferments and in particular of those of young men up to 26 years old is ending up with the establishment of a list of critical industries, to go with the list of critical occupations. It is predicted that there will be a mad scramble by industries to get on the critical list and the wind-up will see a new list nearly as long as the original essential list.

* * *

• The President is now siding with the Army view that civilian production increase should not come just yet. At least this is the impression correspondents were given last week when the President was asked about the dispute over civilian production timing between WPB, the Truman Committee and the Army.

* * *

• Don't look for Congress to press for the early establishment of the Office of Civilian Demobilization which would curb Army say-so on the "when" of Reconversion Day. Word is out from the White House, and even a President-bucking Congress will dare not to disregard practical politics.

If some military program slipped this would give the White House the chance for making political capital of a Congressional boner in starting civilian production too soon.

The upshot is that the period of quiet planning will continue until after the invasion with little action taken until then, unless organized labor starts throwing its weight around. WPB chairman Donald M. Nelson will go as far as he can, though.

The first WPB step will be OK for the regional surplus plan, but this will not come right away. The great obstacle to Nelson is the fact that the public does not know the extent of cutbacks, or their effect, and unofficial censorship still blankets cancellation moves. Also, no accurate manpower statistics are available in the government.

NEW ODT CHIEF: *Brig. Gen. Charles D. Young, deputy director of the Office of Defense Transportation, will assume the duties of director, succeeding Joseph B. Eastman, who died on March 15.*

The Truman report said that cancellations are running at the rate of $1,500,000,000 a month for the first half of this year. At this pace, more than $17,000,000,000 worth of contracts will have been canceled by the Army alone by June.

But no government official will say that cutbacks add labor to manpower supply. Manpower people say that the services will need all men freed through cancellations and this is just what the War Department says, too.

* * *

Along with postwar plans of personal subsidies of $10,000 each for every male adult, to be certified by the government, some of the bright boys remaining in the New Deal are thinking about a World Resettlement Administration. The looming prospect of a world shipping surplus,

SUNICUT

Saves 2 Hours Set-up Time

Transparency permits "on the job" adjustments . . . *tool life up 33%*

Minutes saved in machine shops today mean lives saved on the battlefields tomorrow . . . and here's how a large plant saves 120 of those minutes on a certain operation.

Transparency of Sunicut makes it possible. Previously they had to stop the machines during the operation to make various tool adjustments . . . requiring 2 hours set-up time. At the suggestion of a Sun Cutting Oil Engineer they made a change in cutting oil — to Sunicut, the transparent, straight sulphurized cutting oil.

Now two hours are saved. Sunicut permits a clear view of tools and work . . . adjustments are made without stopping machines . . . two hours idle set-up time turned into two hours vital production.

Added savings in tool life are realized . . . with Sunicut tools cut 33% longer. Operators find Sunicut cleaner to work with . . . and an estimated $5000 yearly saving has been effected since Sunicut requires no mixing with an expensive base.

As a result of this record Sunicut has been adopted throughout this plant. Save production time and money in your plant, too. Apply the advantages of Sunicut to your cutting oil problems. A Sun Engineer can give you full information. Write

SUNOCO

SUN INDUSTRIAL PRODUCTS HELPING INDUSTRY HELP AMERICA

largely American-built Liberties, is the genesis of the notion.

A curious idea is that while some economists are stewing about surplus American war goods, others are thinking of how to get rid of surplus Americans by shipping them to sparsely populated areas where colonization can be promoted and made popular. It is a neat way of solving unemployment. It is a good bet that Europeans are thinking even more about the idea than American government officials. At the same time, wide use of cheap transportation on maritime fleets will go a long way toward offsetting costs of subsidization of the shipping industry after the war.

Colonization targets may be South America, Canada, Australia, the temperate parts of Africa, and the less rigorous portions of Alaska. The whole thing depends upon United Nations agreement and some countries may be reluctant to receive a lot of emigrants.

• P.S. The Steel Division, which at one time had 800 employees, has now less than 450.

* * *

• Representative Wright Patman, Democrat of Texas, won't get very far with his campaign to remove his compatriot, Will L. Clayton, from the job of Surplus Property Administrator and replace him with Jesse Jones.

* * *

• Representative Carl Vinson, chairman of the Naval Affairs Committee, and Representative Andrew May, chairman of the Military Affairs Committee, are having a race to get termination bills to the floor of the House first. Both want to beat the George-Murray bill now before the Senate, and each other.

J. & L. Supply Co. Is New Name for Frick-Reid

• • • **The** Jones & Laughlin Supply Co. has succeeded Frick-Reid Supply Corp., a wholly-owned Jones & Laughlin subsidiary. The change in name was made to identify more clearly the supply company's activities and its relationship to the corporation. The principal office of the new company will remain at Tulsa, Okla.

The new company is exclusive distributor of Jones & Laughlin oil country tubular products east of the Rocky Mountains. In recent years its activities have been enlarged to include process engineering and construction of refineries, gasoline plants, recycling, repressuring and other types of plants for the oil and gas industries.

J. L. Shakely, who has been with Frick-Reid more than 30 years, and president since 1938, has been elected president of the new company. Other officers, including Robert McCoy, Jr., executive vice-president; H. H. Wilson, vice-president, and P. R. Warner, treasurer, have also been elected to serve in identical capacities with the new company.

R. J. Woods will be manager of tube sales of the supply company in the mid-continent area, with headquarters in Tulsa. He formerly was district sales manager for J. & L Steel Corp. in Tulsa and has been succeeded in that capacity by J. H. Tice.

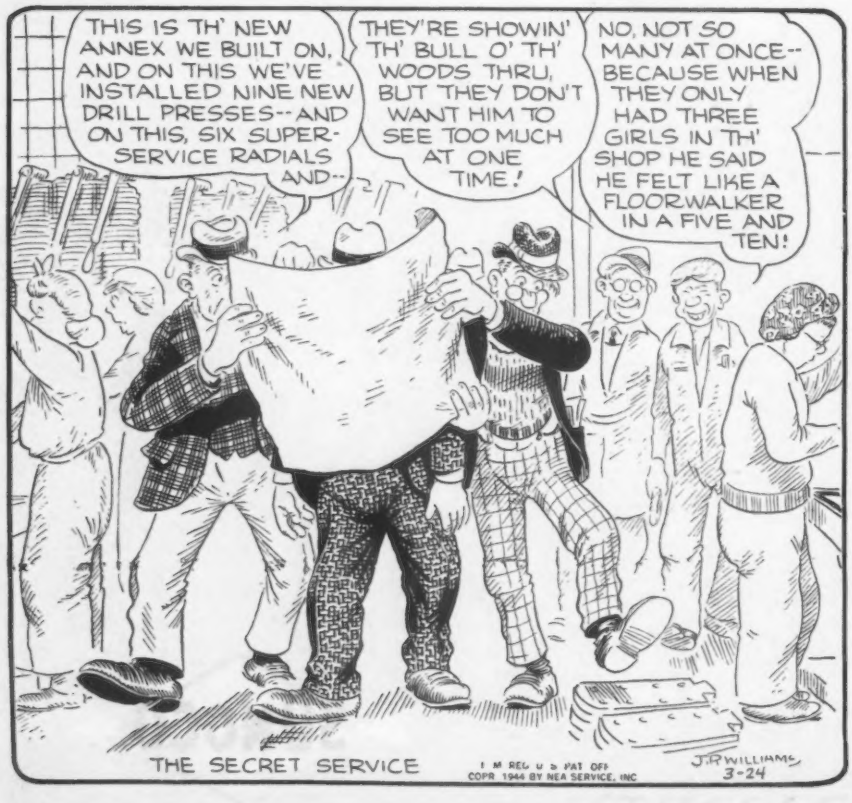
Henry J. McAdams, formerly in New York City, has been appointed manager of Jones & Laughlin Supply Co., New York office.

H. E. Wagner, district sales manager in the eastern oil and gas fields for the supply company, is being transferred from headquarters at Bradford, Pa., to the supply company's offices at 311 Ross Street, Pittsburgh, J. K. Lytle continues in the capacity of assistant to Mr. Wagner.

The Houston office will continue under the direct supervision of H. H. Wilson, vice-president, with T. L. Lewis, who recently joined the organization, as district manager of tube sales. They will be assisted by C. B. Moore, city sales manager; G. S. Emerson, salesman; G. E. Tyson, salesman, and J. T. Batchelor, chief clerk. The latter two were formerly in the tube sales department of Jones & Laughlin Steel Corp.

F. D. Winslow, district sales manager for Jones & Laughlin Steel Corp. in Houston, continues in that capacity, having charge of the sale of all steel products other than oil country tubular goods.

THE BULL OF THE WOODS — BY J. R. WILLIAMS



New Container Institute Is Headed by Keplinger

• • • **Formation** of the Steel Shipping Container Institute Inc., was completed March 16 at New York. L. R. Keplinger, vice president of Rheem Mfg. Co., was elected president. Officers include these vice presidents:

H. N. Lees, president, Draper Mfg. Co., Cleveland; John Hauerwaas, president, United States Steel Products Co., New York; E. C. Gardner, vice-president, National Enameling & Stamping Co., Granite City, Ill.

The board of directors, in addition to those mentioned, comprises the following:

S. A. Bennett, president, Bennett Mfg. Company, Chicago; F. O. Wahlstrom, president, Southern States Iron Roofing Co., Savannah, Ga.; R. P. Dieckelman, vice-president, Pressed Steel Tank Co., Milwaukee; E. D. Thompson, president, Stevens Metal Products Co., Niles, Ohio; J. H. Kerr, vice-president, Ohio Corrugating Co., Warren, Ohio; F. T. Barton, president, J. & L. Steel Barrel Co., New York, and F. J. Nesbitt, president, Owens-Illinois Can Co., Toledo, Ohio.

Exide Maps Supply Lines

How can machine tools help to prevent this kind of Victory?

Remember the big parade of the breadline— the march of the bonus army — the victorious men selling apples? Many an American hero tasted those bitter fruits of victory, and the war to end war ended nothing.

What kind of victory will this one be? It can be the great one American boys are giving their lives for — but they alone can't make it so. For victory in peace, as in war, must be planned ahead . . . and in peace, you're one of the Generals.

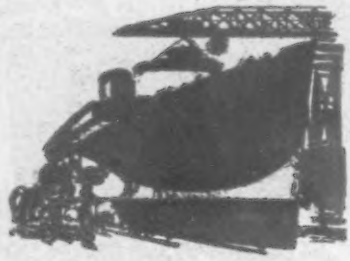
If you are a manufacturer, there is a small group of basic machine tool engineers who can help you to plan now for the kind of victory we've told our sons they're fighting for.

One of these engineers is a Bryant man. We urge you to call him today. For his specialized knowledge of internal grinding machinery is important to the manufacture of literally *everything* that will make this country a finer place: this victory a victory that we shall not be ashamed of.

BRYANT CHUCKING GRINDER COMPANY SPRINGFIELD VERMONT, U. S. A.

WEST COAST . . . OSGOOD MURDOCK

• All Utah rejoices and faces destiny unafraid since WPB authorized completion of structural mill at Geneva . . . Major California scrap dealers completely vindicated by Federal courts.



SAN FRANCISCO—Balm has been flowing as from an artesian well throughout the intermountain Gilead of Utah since the cryptic announcement came from Washington that WPB has changed its mind of three months ago and will now authorize the completion of the structural steel mill at the Geneva plant. Senators, Congressmen, the Governor, the State University, Chambers of Commerce and representatives of the railroads have combined in making their representations and carrying the appeal to Washington through every channel and pipeline available. Salt Lake newspapers have so headlined the affair that citizens or Utah generally have become well acquainted with complexities of the steel industry to a surprising extent.

Vice President E. M. Barber of Columbia Steel Co,., construction contractors for DPC, estimates that between 60 and 70 per cent of the machinery and equipment for the structural mill is now stored in the great building, which is about 90 per cent complete. Practically no erection or installation has been done and if and when all additional facilities are delivered the mill could be operating within about 90 days, after construction is resumed. Ample labor is now available, but material priorities will have to be reinstated and many suppliers have substituted other orders since the stop order was issued early in December. The 26 inch mill when complete will have an annual capacity of 200,000 net tons of structural shapes, billets and rounds. Present prospect indicates that first products may be available late in the summer or early in the fall.

From an operating standpoint, principal advantage of the structural mill is to balance the operation and utilize most efficiently the three blast furnaces and nine open hearths designed to supply ingots for the structural mill as well as the big plate capacity. Furthermore, in connection with postwar conversion, it is generally expected that the demand for plate will cut off when ship construction is terminated, and while plate facilities are being converted to roll strip and sheets, the structural mill would be an anchor to hold the organization and continue operation.

TRAFFIC experts from Utah have been in Washington conferring with DPC and ICC agencies over the crucial question of freight rates on finished steel products to the West Coast. The present rate per gross ton on pig iron from Geneva to Los Angeles, San Francisco, Portland or Seattle is $4.95 and on ingots $5.78. This is reasonable and satisfactory and considerable tonnages have been moving on this basis. On cast iron pipe made at Provo the rate has been $6.60 although no great volume moved during normal times because of the lower water rate from Birmingham. On finished steel, plates, shapes and bars, the book rate now stands at $12 per net ton, somewhat in line with the rate of $17 per ton from Minnequa (Pueblo) Colo., and $22 per net ton all rail from Chicago or Birmingham.

Recently Kaiser steel was granted a rate of $4.40 on plates from Fontana to San Francisco, a distance of 518 miles. On the basis of this rate and other considerations, the Utah traffic authorities urge a rate of $5.31 from Geneva to Pacific Coast ports. Recently DPC rate experts submitted a suggested schedule to the railroads as follows: Geneva to Los Angeles $5.95—to San Francisco $7.30—to Portland $7.75—to Seattle $8.00. The respective rail mileages involved are 746 miles to Los Angeles, 849 miles to San Francisco, 922 to Portland and 1009 miles to Seattle. In direct ratio to these mileages, on the basis of the recent Fontana to San Francisco rate of $4.40 the respective rates to Los Angeles, San Francisco, Portland and Seattle from Geneva would be $6.35, $7.20, $7.80 and $8.50. A single, equalized uniform rate to all four principal Pacific Coast ports seems desirable and the probable volume and industrial possibilities justify close and careful consideration. In fact the entire economy and future of the Geneva operation depend almost entirely on what the rail rate to Coast points may be. However, competitive implications are such that the adaption of this rate is such a crucial factor in the future industrialization of the West Coast that whatever the final decision, it will be frightfully unsatisfactory and violently distasteful to various interests involved.

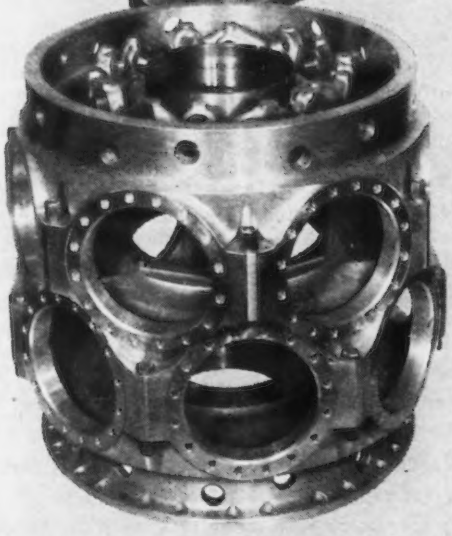
ON the basis of the long awaited decision of the United States Supreme Court in the Hecht case two California Federal District judges promptly and decisively found in favor of the defendants and against OPA in the tedious but important actions involving principal scrap iron suppliers.

California Scrap Iron Corp. of Oakland, San Francisco and Pittsburg and its able, outstanding president Marshall A. Shapiro were completely vindicated and exonerated by judge Louis A. Goodman who promptly vacated his former judgment and found in favor of the defendant. In Los Angeles Judge Ben Harrison had held the case of OPA versus Berg Metals Corp. under submission "for a considerable length of time because I was dissatisfied with the holdings in Brown versus Hecht."

Judge Harrison, the very next day after the Hecht decision was announced, issued memorandum opinion in part as follows:

"Now that the Supreme Court of the United States in a very salutary and wholesome decision has reversed the Hecht case and held in effect that the trial courts were not rubber stamps for OPA I shall proceed to dispose of the issues: I find that . . . shipments in violation . . . occurred through inadvertance and an honest misunderstanding . . . clarified by amended regulations . . . at the time of filing was in full compliance . . .

There's no substitute for EXPERIENCE!



Increased production attained in precision machining of this aircraft crankcase on the above Ex-Cell-O special-purpose machine.

Ex-Cell-O's wide experience in designing and building special machines to increase output and lower costs assures you practical advantages in your immediate or near future production

You have a substantial background of experience to draw from when you bring to Ex-Cell-O your problem in the *precision* machining of metal parts on a high production basis . . . whether it concerns an immediate war production job or a future product you are now planning. The more economical production of accurate metal parts necessitates single-purpose machines of improved efficiency, capable of giving greater output and reducing unit cost. For years Ex-Cell-O has been an acknowledged leader in the field of special-purpose machines . . . *precision* machines with exclusive features that represent the utmost in accuracy, production, operating ease, rigidity, and durability. This is why you should utilize Ex-Cell-O's experienced engineering and manufacturing facilities. Ex-Cell-O has representatives in all of the nation's principal manufacturing centers. Consult the one nearest you, or write to Ex-Cell-O Corporation Head Office in Detroit.

no evidence indicating any further violations.

"The plaintiff (OPA) presented this case on the theory that he was entitled to an injunction as a matter of right upon the establishment of any violation of any provision of the regulations and stipulated that at the time of trial the defendants were in full compliance and that he had no evidence indicating the necessity of an injunction.

"As to other alleged violations, I find against the plaintiff.

"In view of the fact that the issuance of injunction in cases of this character are still a matter of discretion, the application for injunction against the above defendants is denied."

THESE simultaneous, decisive actions by the two courts finally disposed of matters that have hung fire for nearly two years, during which the left wing legal staff of the OPA regional office at San Francisco has been backed further and further onto an untenable limb now mercifully sawed off. The two largest, most reputable and most important suppliers of scrap metal on the Pacific Coast were singled out and hauled into court for minor technical violations of a complicated regulation, involving trivial and inconsequential amounts, representing no profit or advantage and accomplishing no purpose in the war emergency. Fortunately the two firms involved had sufficient material resources and self respect to refuse to sign consent decrees and to resist through the Federal courts where the judge previously commented "if the rules of equity were controlling the court would not grant an injunction in this case."

Despite the discomfort, hardship, cost and seemingly unnecessary onus of these actions, the firms accused and others have continued to observe scrupulously the letter and spirit of OPA scrap ceilings and regulations, and fortunately the vindictive and technically sacrosanct attitude of the OPA legal department has not permeated the price section which has been practical, understanding and reasonable. The firms accused have actually gained prestige by the experience, in the respect of fellow members of the trade and in carrying the torch for the entire industry.

WHEN President P. G. Johnson of Boeing and J. H. Kindelberger of North American attended a recent Los Angeles meeting of the Aircraft War Production Council they jointly and officially made important and encouraging summaries of the general West Coast aircraft situation. For southern California only 3000 workers are short now, and a few months ago it was supposed to be some 30,000. Boeing is now short 2000 at Seattle but it was 8000 or 10,000 desperately plugged by the entire Pacific Northwest last fall. Less than one half of one per cent of all aircraft employees are in the 18 to 21 age group. All men under 22, including pre-Pearl Harbor fathers, add up to a little over 3200, a negligible percentage. But there are 15,000 men in the 23, 24 and 25 year brackets, most of them key workers and virtually irreplaceable, at least during the emergency. As to surplus materials and idle inventory, Mr. Johnson states that inventories have been steadily reduced by all council companies in the last year. "Actual surplus material of this type for each of the ten West Coast prime airframe plants is insignificant in comparison with the dollar value volume of work in process and on order with suppliers and vendors throughout the nation. Hence the major disposal problem in aircraft material at the war's end will concern raw materials in process, semi-fabricated or in transit, rather than the present surplus inventories."

West Coast Aircraft Output Soars to New High in February

Los Angeles

• • • **West Coast aircraft** production for February again points to the trend toward bigger, heavier, and deadlier planes. Despite the shorter month and inclement weather, output jumped to an all-time high of 32,469,000 lb., or 2569 planes from West Coast plants. This output compares with 31,892,000 lb., or 2559 planes produced in January, reflecting a steadily increasing labor utilization since February employment remained about the same as that of January.

While February production was only 10 planes over January in terms on finished units, it was 577,000 lb. over the 31-day month in terms of weight.

Based on the average weight per plane produced in 1942, which was 9288 lb., February production this year was equivalent to the output of 3496 planes of 1942 models and January production was equivalent to 3434 planes.

Average weight per unit during the past two years has increased in this manner: 1942, 9288 lb.; 1943, 11,673 lb.; January, 1944, 12,463 lb.; and February, 1944, 12,639 lb.

There is a definite switch in type of aircraft made discernible from the statistics on the increase in unit weight. The emphasis now is definitely on bigger bombers and huge transports. If an index is made up whereby the average lb. output per month during 1942 was a norm of 100 per cent, then January, 1944, production index of West Coast companies was 233.1 and February, 1944, production index was 237.3. Using the same index, production during 1943 went from 132.2 for January to 225.7 for December, with an average of 185.7 for the year.

ACCURATE? IT'S A MICROMETER with a 300,000 POUND SQUEEZE

Another DENISON HydrOILic Press!

With this HydrOILic straightening press the operator can handle one-of-a-kind jobs as fast as they come along, and control the pressure "as he goes" with inch-by-inch, pound-by-pound accuracy! On the other hand pressure limits may be pre-set at any point from 15 to 150 tons, and ram stroke can be pre-set anywhere up to 20 inches. Speed of stroke can also be varied.

Such flexibility and fluid power control makes this DLSC2-150 Press as highly efficient on small-lot or single-job operations as it is on volume production work. Tools and fixtures can be changed easily too, adapting the press for bending, assembling and other jobs. No wonder enthusiastic users call it a "micrometer with a 300,000 pound squeeze!"

The DLSC2's compact, fully-enclosed, round-cornered design, extra toe space and other features—typical of all Denison Presses—give the operator safe, easy access to the work area. Available with either foot-pedal or hand-lever controls—or both. Other DLSC2 straightening presses have capacities of 25, 50 and 100 tons. Let us send you information on the complete line. The Denison Engineering Co., 1158 Dublin Rd., Columbus 16, Ohio.

• **Peter V. Martin** has been appointed chief of safety of Carnegie-Illinois Steel Corp., Pittsburgh. He was superintendent of blast furnaces at their Gary Works since 1941, and has a 29-year service record with the company.

• **Mary Groff** after many years of service as assistant to the advertising manager of THE IRON AGE is resigning to make her home in New England. She joined the organization after she graduated from Barnard College and served in many important positions in the business department.

• **Daniel C. Green** has been elected board chairman of the Cleveland Pneumatic Tool Co. and its subsidiary, Cleveland Pneumatic Aerol, Inc., and **George P. Torrence** has been elected president.

• **S. L. Feduska**, research metallurgist of Indiana Steel Products Co., Chicago, since September, 1943, has been appointed plant metallurgist in charge of foundry, heat treating and forging department. Before joining this company he was connected with the Continental Roll & Steel Foundry Co., and the United Engineering & Foundry Co., Pittsburgh, Pa.

S. L. FEDUSKA, plant metallurgist of Indiana Steel Products Co.

• **Gerald A. Lux** has been added to the technical staff of Oakite Products, Inc. He will make his headquarters in New York.

• **Frederick P. Culbert**, recently resigned American Vice-Consul at Casablanca and long-time French representative for the United Aircraft Corp., has been appointed general manager of the Al-Fin Corp., a wholly owned subsidiary of the Fairchild Engine & Airplane Corp.

• **J. O. Wible** has been elected president of Union Electric Steel Corp., Pittsburgh. Mr. Wible previously filled the unexpired term of Earle G. Winner, who resigned the presidency due to ill health. **Robert C. Good** has been appointed sales manager. **R. S. Gorman**, works manager, will continue to direct plant operation and certain marketing.

E. W. POTRATZ, manager of the hoist sales division, Harnischfeger Corp.

• **John K. Colgate** has been elected president of Tyson Bearing Corp., Massillon, Ohio, succeeding **Ralph Maxson**, who resigned recently. Mr. Colgate has been vice-president and treasurer of Tyson for three years.

• **E. W. Potratz** has been appointed manager of the hoist sales division, Harnischfeger Corp., Milwaukee. He joined the Harnischfeger hoist division as an estimator in 1935, and in 1939 was named assistant sales manager. Since 1942, he has been acting sales manager.

JOHN P. BERNARD, vice-president and general manager of The Sheffield Corp.

• **John P. Bernard** has been appointed vice-president and general manager of the Sheffield Corp., Dayton. He joined the Sheffield organization in 1942 after spending 17 years with the Dyer Co., Inc., Cleveland. At the time he left this company to join Sheffield, Mr. Bernard was executive vice-president in charge of operations.

• **Harry M. Heckathorn** has been elected vice-president in charge of production of Mullins Mfg. Corp.'s Salem and Warren plants. The appointment was made following the resignation of **Howard F. Kulas**, vice-president in charge of operations at Salem, who is leaving because of ill health. Mr. Heckathorn has been vice-president in charge of operations of the Youngstown Pressed Steel division plant in Warren since 1938 and will now be responsible for the operation of the three Salem plants as well.

• **James Cope** formerly head of the Washington bureau of the Automobile Manufacturers Association, has been appointed assistant to K. T. Keller, president of Chrysler Corp., New York.

• **E. Q. Smith**, formerly vice-president of Bundy Tubing Co., Detroit, has been made president of Agaloy Tubing Co., Springfield, Ohio; **W. W. McMinn** has been made vice-president; **John J. Judge**, factory superintendent; **W. H. Lohman**, purchasing agent; **Albert Katz**, development engineer; **William Spears**, project engineer; **L. M. Clark**, personnel director and **Lester M. Elliott**, assistant secretary and treasurer.

J. N. YORKE, controller of Superior Steel Corp.

• **J. N. Yorke** has recently been elected controller of Superior Steel Corp., Carnegie, Pa. He joined Superor in 1941, coming from Haskins & Sells, certified public accountants, and was promoted to auditor in 1943.

• **Joseph Duffy** has been made sales manager of the Irving Subway Grating Co., Long Island City, N. Y. He has been associated with the firm in a sales capacity for the past two years. In his new position he will direct a large sales force with representatives in every state.

• **Charles Schwarzler** has been appointed manager of the export department of the Foxboro Co., Foxboro, Mass., succeeding **Henry B. Moelter.**

• **H. J. Carroll** has been appointed secretary of the Southern Pacific Co., with headquarters at San Francisco.

• **Charles W. Sprenger** has been made district manager for the metropolitan New York district of the Carborundum Co., Niagara Falls, N. Y. Mr. Sprenger succeeds the late **John Storm. Joseph C. Steele** has been made district sales office manager at New York.

• **Neil C. Hurley** has been made chairman of the directors of the Independent Pneumatic Tool Co., Chicago, and **Neil C. Hurley, Jr.,** has been elected president. **Edward G. Gustafson,** treasurer of the company, and **John McGuire,** secretary, were elected to the board of directors.

• **Bruno R. Neumann** until recently senior economist with the planning division of the WPB, has joined the National Foremen's Institute, Inc., Deep River, Conn., as labor economist and editorial director.

•**Henry E. Hermann,** has been appointed works manager of the Bear Mfg. Co., Rock Island, Ill., in charge of all production.

• **J. F. Woessner** was appointed assistant comptroller in charge of staff activities and general duties for Carnegie-Illinois Steel Corp., Pittsburgh. Mr. Woessner was formerly general works auditor in the company's Pittsburgh district, and had previously served as treasurer, assistant secretary and comptroller for Pittsburgh Coke & Iron Co. **M. W. Krueger,** supervisor of the Pittsburgh district organization planning department since 1942, was made assistant comptroller in charge of works accounting. He was formerly associated with the Kimberly Clark Corp., Neenah, Wis. **A. B. Cook,** assistant comptroller in charge of general office accounting, will continue in that capacity.

• **L. P. Jackson,** vice-president in charge of engineering, Mid-West Abrasive Co., Detroit, was elected a director of the firm. **Carlton M. Higbie** also was named a member of the board.

W. LYLE RICHESON, assistant vice-president of American Car & Foundry Co.

• **W. Lyle Richeson** has been appointed assistant vice-president of American Car & Foundry Co., New York. Mr. Richeson has been associated with the company for a period of 19 years. **William R. Kottsieper** has been appointed manager of the valve department. He has been associated with the company over a period of 38 years. **W. A. Gormley** and **L. A. Ward** has been made sales manager and assistant sales manager of valves, respectively.

OBITUARY...

• **Richard H. Scott,** president and general manager of Atlas Drop Forge Co., Lansing, Mich., died Mar. 11. Previously he had risen from the superintendency of the then-small Reo Motor Car Co. to become its president.

• **Maurice Pollak,** widely known steel manufacturer and president of the Pollak Steel Co., Cincinnati, died recently after a long illness. He was 67 years old. Mr. Pollak, a native of Cincinnati, entered the steel business at the bottom of the ladder in his father's plant and filled many offices before becoming president.

• **Edward R. Estberg,** treasurer and director of the Waukesha Motor Co., and of the Hein-Werner Parts Co., both of Waukesha, Wis., died in Milwaukee, March 3, after several weeks illness.

• **George M. Bower,** president of Ross Operating Valve Co., died in Detroit, March 8 at the age of 51. He was a member of the American Society of Tool Engineers.

• **Calvin L. Day** died at Montclair, N. J., on March 13. He was with the Robins Conveyor, Inc.

• **Eugene E. Hinkle,** retired president of the Hinkle Iron Works, senior partner in the E. E. & Terry Hinkle Co., and director of the Peabody Engineering Co., died March 7 at Westport, Conn. He was 78 years old.

• **Arthur W. Batcheldor,** mechanical engineer with the Ford Co., Somerville, Mass., for 15 years, died at Lynn, March 3. Before going to Ford he was associated with the Baldwin Locomotive Works and Pennsylvania Railroad.

• **William Bibbey,** 50, former owner of the Mystic Wire & Iron Co., Boston, died March 7. At the time of his death he was associated with the Quincy Ornamental Iron Co., South Boston.

Fatigue Cracks

BY A. H. DIX

War Plant Scoop

• • • Among the additional burdens the war has placed on our back is that of keeping in the good graces of the censors. This is one of the loads that does not bear too heavily on us, owing to the censorship authorities' highly intelligent application of the regulations. *(Our admiration for the censors has been boundless ever since one of them wrote us, "Your editorial material contains information that is much newer and up to date than other journals.")*

Our burden is further lightened by the cheerful cooperation of war plant press agents. Here, for example, is a photograph of a highly specialized piece of production equipment in the huge Dodge Chicago plant, where 18-cyl. airplane engines will be made.

This machine, the release informs us, makes doughnuts. We are relieved of any fear of censorial repercussions by the press agent's thoughtfulness in informing us that the photo has been cleared by the A.A.F. Materiel Command.

They look like crullers to us.

Reactionary

• • • In the "Letters to the Editor" page of the English aircraft journal, *The Aeroplane*, a reader asked if President Roosevelt said "aeroplanes" instead of "airplanes" in a recent broadcast. The editor answered:

> Possibly the rolled "r" of American speech may have made the word airplane as spoken by Mr. Roosevelt sound to a conservative ear like the good British "aeroplane." We hope not.

Even though "aeroplane" flows more smoothly over the tonsils, the editor's hope is in vain, for the streamlined term has not only established complete supremacy here but is making substantial inroads in England. We will give three to one odds that by 1950 *The Aeroplane* will have changed its name.

Left Hand Twist Drill

• • • The final chapter in the left hand twist drill controversy, whose genesis was the southpaw drill shown in "The Bull of the Woods" Dec. 9 cartoon, is written by Ernest L. Lynn, Editor, Comic Art Department, NEA Service, which distributes J. R. Williams' cartoons:

> Since Mr. Williams resides in California and letter writing is one of the things he is distinctly not fond of, I thought it better to answer your inquiry myself.
>
> Although it is true that left hand drills are made and used, nonetheless this was a little slip-up on the part of the artist. These, as you know, are rare, since I believe he could draw every tool in a machine shop blindfolded and do it correctly . . .

Advertising Striptease

• • • We have just seen an astonishing document prepared by your favorite family journal's Department of Research. The head of this department is Oliver Lewis Johnson, an individual in whom is combined a scientist's passion for the whole truth and nothing but, and a constitutional inability to abandon a trail.

He took upon himself the staggering job of analyzing the 7,921 pages of advertising (some 12,000 separate advertisements) in our last year's issues. He analyzed the ads by products, by groups of related products, and by companies, and has presented his findings in a 20-page report, which is as frankly revealing as the art lovers' books advertised in the pulps.

In it are listed the 1,016 advertisers (classified excluded) who wooed you through our pages last year, and opposite each name is the extent of their wooing, in number of pages. Biggest wooer was Westinghouse Electric, with 70.83 pages. Runner-ups were Bethlehem Steel and G.-E. Schenectady, with 64 each.

As a group, the machine tool builders were first, with 1,081 pages, about one-seventh of the total. At the low end of the scale was layout blue industry with one-third of a page.

Not only are the advertisers listed from A to Z, with aggregate space each used, but in addition the space each used for each individual product is specified.

This strip tease, with satisfying finale, is possible only because this journal, with an advertising body beautiful, has nothing to conceal. Being first in volume, it can show all — and does in an unabashed, unadorned way — thanks to Oliver L.

Pen Points in Nine Figures

> You say on page 97, Mar. 9 issue, that among the lend-lease material available for sale by the Treasury Department Procurement Division is 400 tons of pen point steel.
>
> You add that this is capable of producing "quite a few pen points." Can't any of your people weigh up a pen point and figure out how many could be made from the 400 tons?
>
> —*Deac*

The pointer on the scale in our mailing department hardly wiggled when we dropped a pen point into the pan. So we took it (an Esterbrook No. 788) over to Liggett's drugstore across the street. It weighs 1/44th of an ounce, the druggist told us.

Allowing 50 per cent for waste, you get 22 points out of an ounce of steel. The 400 tons of steel would be enough for 281,600,000 pen points.

The other day we heard of an abandoned midwestern defense plant that had several thousand snow shovels. The margin of safety in Government buying is breath taking.

Felicitous Phrasing

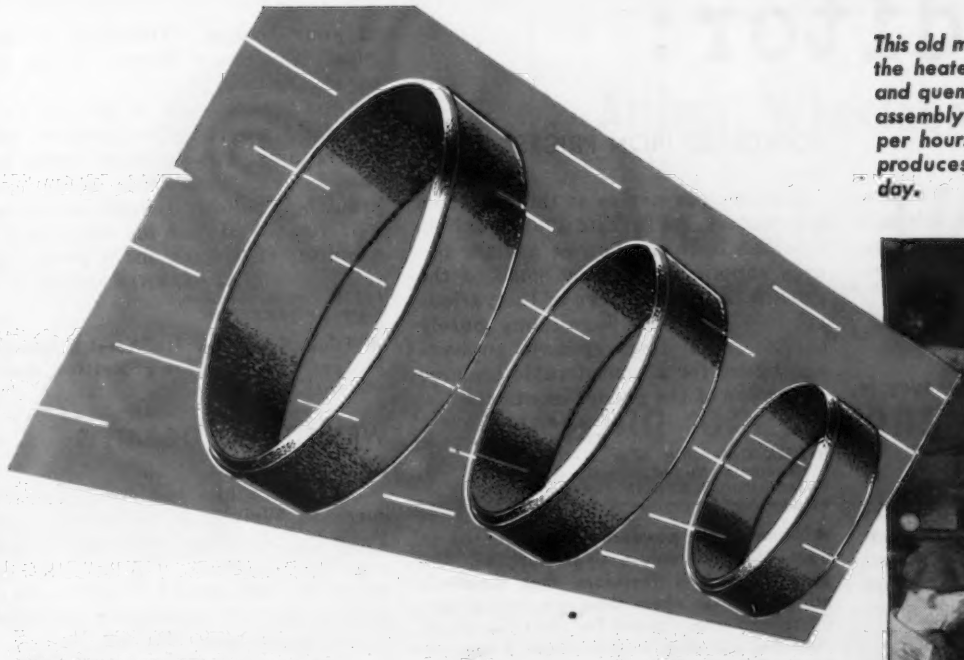
> Indications are that if the (Boykin "Steel Shortage") committee were given its way, OPA couldn't furnish enough brown ration stamps to purchase the political pork with which the South and the West would be flooded . . .
>
> —*From a Washington dispatch, page 100, March 9* IRON AGE

Puzzles

You can cheat last week's troublemaker out of a turkey by starting the counting with the third person to the left of him, and counting clockwise.

You can establish your own par for this dandruff agitator sent in by C. R. (Braeburn Alloy Steel Corp.) Cline:

> *The sum of three values equals one; the sum of their squares equals two, and the sum of their cubes equals one. Determine any three values that will satisfy all three equations.*



This old method of putting the heated ring on a jig and quenching the whole assembly produced 8 rings per hour. Super-Cyclone produces 432 rings per day.

The Lindberg Super-Cyclone Keeps Work Straighter

saves time . . . cuts costs

REDUCING the need for difficult straightening, or eliminating costly preventive measures, can speed up heat-treating production and save in many ways. The Lindberg Super-Cyclone Furnace is doing just this for users because of the heating principle on which it operates. Fan-driven hot air developed in an isolated chamber builds up temperature with rapid uniformity *throughout the charge* to as much as 1750°F. There is no direct radiant heat to cause distortion.

A bearing manufacturer placed each "race" on a special jig to hold an acceptable "round" after quenching. Produced 64 per 8 hour day. With the Super-Cyclone an operator working only 1½ hours a day, loading 63 rings at a time on a fixture, quenching all at once without jigs, yet holding to within .006" to .010" of round, finished 432 per day—*7 times more production.*

Besides keeping work straighter, saving time and saving space, the Super-Cyclone can be used for normalizing, hardening and tempering, because temperature can be accurately controlled between 300° and 1750°F.

Write for complete information to: Lindberg Engineering Company, 2452 W. Hubbard St., Chicago 12.

LINDBERG FURNACES

ARMY NAVY

SUPER-CYCLONE for hardening, normalizing, annealing, tempering
CYCLONE for accurate, low-cost tempering and nitriding
HYDRYZING for scale-free and decarb-free hardening

Dear Editor:

CONTINUOUS CASTING

Sir:

May I congratulate your Mr. Lippert most sincerely upon his splendid article in your Feb. 24 issue on continuous casting. Is there any intention of reprinting it?

GEORGE D. HARTLEY
372 May Street,
Worcester, Mass.

● It has been reprinted and a copy is being sent you.—Ed.

TRICLORETHYLENE SOLVENTS

Sir:

Your Mar. 9 issue contains an article, "How to Use Triclorethylene Solvents," by Herbert H. Hines, Springfield, Vt. Kindly advise me from whom this material can be purchased.

W. WALLACE McKAIG
Cumberland Steel Co.,
Cumberland, Md.

● There are a number of makers and distributors, among them the E. I. du Pont de Nemours & Co., Wilmington, Del., and Detrex Corp., 13005 Hillview Ave., Detroit.—Ed.

BONDERIZING

Sir:

Can you tell me the name of the company responsible for the metal finish called Bonderizing?

JAMES DUNCAN,
Heat Treat Department
Standard Products Co.,
Port Clinton, Ohio

● Parker Rustproof Co., 2177 E. Milwaukee Ave., Detroit, Mich.—Ed.

TOOL FORECAST

Sir:

Our Chief Tool Engineer would very much like to secure a reprint of the article, "Forecasting Tool and Gage Requirements," by Sergius D. Brootskoos, in your issues of Mar. 9 and 16. Are reprints available?

MARGARET M. FLEMING,
Librarian
Republic Aviation Corp.,
Evansville, Ind.

● No reprints have been made, but clippings have been sent you.—Ed.

BRAZILIAN IRON ORE

Sir:

A friend of mine asked me to find out the conditions under which he could export iron ore from Rio de Janeiro, Brazil, to this country. I would be glad if you could inform me about buyers, conditions of payment, duty, and shipping conditions for about 3,000 tons of ore per month.

ARLINDO DE BARROS VALENCIA
235 W. 108th Street,
New York 25

● Few companies here are interested in importing iron ore as most here have their own domestic ore reserves. Some of the new Texas steel plants might eventually show some interest but currently are developing their own Texas ore bodies—Ed.

POWDERED IRON PRICES

Sir:

How do you arrive at the powdered iron quotations in THE IRON AGE? Is there an open market, or are the figures supplied to you by some of the producers or consumers of the various grades? Are the quotations purely nominal, or do they represent an average figure for a considerable tonnage of powder of the grades mentioned?

F. A. FORWARD,
Technical Director
British Columbia War Metals Research Board,
University of British Columbia,
Vancouver, Canada

● Some of the powdered metals quoted on page 160 have only a single supplier. The price quoted is therefore that supplier's price. In cases where there are several suppliers, and where prices for the same grade vary, the quotation is an average. Prices are for ton lots. Some producers add a differential for smaller quantities. Some do not.—Ed.

EDITORIAL INDEX

Sir:

We shall appreciate it if you will send us two copies of the index for 1943.

E. F. BURTON,
Chief Engineer
Douglas Aircraft Co., Inc.,
Santa Monica, Cal.

● Editorial indexes are issued semi-annually. Copies are supplied gratis upon request.—Ed.

COPPER ALLOY CASTINGS

Sir:

Will you please send us six tear sheets of the article, "Better Copper Alloy Castings," by H. E. McGowan, in your Mar. 2 issue.

W. M. ELSTUN,
Secretary
Hammond Brass Works,
Summer Blvd.,
Hammond, Ind.

Sir:

We have read with interest the article, "Better Copper Alloy Castings," by H. E. McGowan in your Mar. 2 issue. Could we get two copies of it?

WALTER M. MITCHELL
York Safe and Lock Co.,
Special Ordnance Plant,
York, Pa.

BLAST FURNACE REFRACTORIES

Sir:

We read with great interest Dr. Joseph M. Robitschek's article, "Carbon Refractories for Blast Furnaces," in your Feb. 3 issue. We are very anxious to obtain several reprints.

R. M. MAXWELL
Koppers Company,
Tar & Chemical Div.,
Pittsburgh, Pa.

● Clippings have been sent you.—Ed.

TOOL STEEL DIRECTORY

Sir:

I am enclosing 25c to pay for a copy of your booklet, "Directory of Tool Steels and Other Metal Cutting Materials."

I am very anxious to get a copy of this for I am a steel bookkeeper. This job requires you to know steels and that is why your book would be a great help to me. I would appreciate it if you would rush my order as it is a matter of helping me a great deal.

MISS WINNIE ROBERTS
14779 Lydia Avenue,
East Detroit, Mich.

● Price of the new Tool Steel Directory is $1. For more than five copies the price is 50c each.—Ed.

WRIGHT PHOTOGRAPHS

Sir:

Some time ago you took some pictures at Wright Aeronautical Corp., Paterson, N. J., and published them in your Jan. 13 issue. I've looked everywhere for this issue but can't seem to find a copy. I'd appreciate it so much if you would send me one.

MISS ETHEL CASTAKOS
108 Madison Street,
New York 2

● It seems that everyone who appeared in any one of the 15 photographs that illustrated H. E. Linsley's article, "Machining the Wright Cyclone Forge Cylinder Head," has written us for a copy of it, with the result that we have none left. If any reader is willing to part with his Jan. 13 issue and will send it to Miss Castakos direct or to us, both she and we will be grateful.—Ed.

ANNEALING

Sir:

We did not receive our July 15 issue and find that none of the other Sheffield firms has a copy. We are desirous of seeing the continuation of the series on "The Annealing of Steel," by Peter Payson. Will you send us a copy or tear sheets?

GEORGE H. DAVISON
United Steel Companies, Ltd.,
Central Research Dept.,
Stocksbridge, Nr. Sheffield,
England

● The entire series has been reprinted by the Crucible Steel Co., of America, 405 Lexington Ave., New York 17.—Ed.

PASSIVATION

Sir:

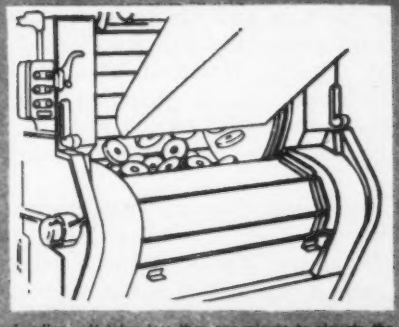
In answer to an inquiry on passivation of stainless steel, you insinuate that accomplishment can be had only by use of nitric acid. Is this necessarily so?

We have recently been using ferric sulfate with apparent success but would appreciate your comment as to its true worth in this respect.

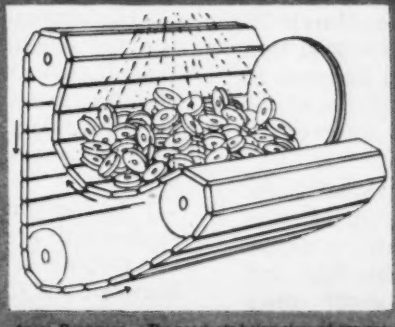
E. A. HILL,
Mech. Engineer
Palnut Co., Inc.,
Irvington 11, N. J.

● Practically all stainless steel passivation is carried out in about 15 or 20 per cent nitric acid by volume, at a temperature of 130 to 150 degrees F. The steel is usually immersed for 20 to 30 min. As to ferric sulfate, the Monsanto Chemical Co. has recommended this as a passivating agent. This technique is new, and we do not know whether enough data have accumulated to permit of a definite answer.—Ed.

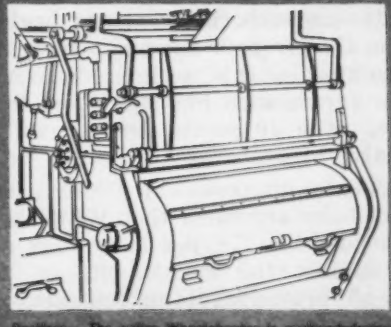
Airless Wheelabrator Tumblast Principle *CUTS TIME* and *COSTS* on metal cleaning operations in our plant



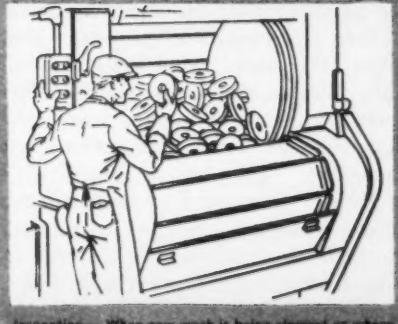
Loading — It takes less than one minute to elevate the loader and charge the machine. While the Wheelabrator is cleaning one load the next charge is dumped into the loading bucket ready for charging. The loader is operated by an individual motor which is controlled by a push button limit switch. Eliminates waste motion, and permits almost continuous operation.



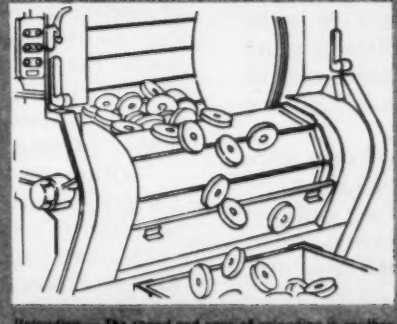
Apron Conveyor — The products being cleaned are cascaded one over the other and completely exposed to the full abrasive blast. Each piece is cushioned in its slide by the one next to it. Breakage of fragile pieces is practically eliminated. The endless apron type conveyor is one of the exclusive features of the Tumblast, which permits quick and easy loading, unloading and inspection.



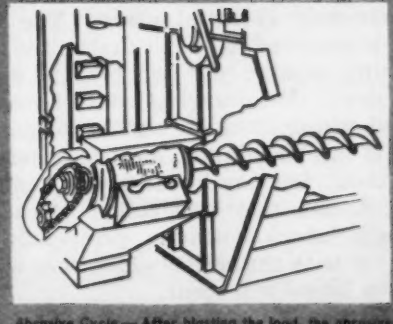
Dustless — The entire Wheelabrator is enclosed during operation, making it a safe, dust-tight unit. The door and the conveyor apron seal the front. The back is completely enclosed. All hand holes, providing access to the mechanism, are covered. A special exhaust directly above the cleaning chamber permits dust removal without the loss of good abrasive.



Inspection — When new work is being cleaned or where the cleaning time is not yet established, it is unnecessary to overclean the work. The load can be inspected at any time during the cleaning process. Only a few seconds are required to stop the machine, open the door and make an inspection. If desired, the conveyor can be operated during inspection to keep the work tumbling.



Unloading — The speed and ease of unloading is another important feature. Unloading is accomplished by reversing the travel of the apron conveyor, which carries the work up and out of the cleaning chamber, spilling it into a receptacle. This method of unloading eliminates all manual handling. Complete unloading is accomplished in from thirty to sixty seconds.



Abrasive Cycle — After blasting the load, the abrasive falls through holes in the conveyor plates and drops into a hopper directly below. A screw conveyor carries the abrasive to a screen where all refuse is removed. The cleaned abrasive is elevated to a sand separator and overhead storage hopper, from which it feeds by gravity into the Airless Wheelabrator blast unit.

World's Largest Builders of Airless Blast Equipment

This Industrial Week . . .

- ***Telescoping of Delivery Schedules Noted in Steel Industry***
- ***Production Losses Expected Due to Tighter Draft Rulings***
- ***Improvements in Product Mix of Steel Mills Reported***

HIGHLIGHTS this week include the telescoping of delivery schedules on additional invasion equipment, the tighter manpower picture resulting from stricter draft rules expected to be a brake against production, and an improvement in the steel mill product mix due to stronger buying of bars, alloy steel and other items.

Meanwhile, the industry's attention centered upon the deliberations of the National War Labor Board over the steel wage issue. The WLB was expected on Tuesday to authorize hearings beginning March 22 on the 17c per hour demand. It was understood that at the start of this week the USWA had dropped 10 of its 24 demands but still stood firm on its major points. The 10 points dropped will be referred to collective bargaining.

Counter proposals by United States Steel Corp. included the argument that WLB has no jurisdiction to consider the 17c. per hour wage demand, a provision against the maintenance of membership and check-off provisions of a contract, and eight other points.

The rush to complete invasion equipment may result in a large share of this material being completed before the tightened draft rules bite deepest, but the steel industry expects from 5 to 10 per cent of its younger workers probably will be lost through the government's decision to draft men under 26 except in extremely essential cases. The impact in some mills is expected to be felt first in the conditioning and finishing departments and then to work back toward raw steel. Metallurgical control may be hit by the loss of young chemists and metallurgists.

At the Washington meeting where steel men were told about the new draft policy, industry executives pointed out that production already has suffered through labor shortages, principally common labor, and that with the arrival of warmer weather more production losses will occur.

SHORTAGES of labor already have resulted in loss of tonnage through inability to accomplish such routine tasks as roll changes and furnace repairs in normal time. One company estimates its loss because of repair lags at 7000 tons per month, and another smaller mill places its loss at about 5000 tons per month. Departments specializing in scheduling, inspection, carloading, etc., will be effected also.

The problem facing all war goods makers is emphasized by the statement of a Moline, Ill., company that it is giving up its sizable shell forging contract because of inability to get labor.

Deferments for all tool and die makers having one and one-half years apprenticeship were asked at Washington Monday by the National Tool & Die Manufacturers Association. L. A. Sommer, Cleveland, president of the group, said 50,000 men in the 2500 tool shops of the nation are on the verge of being drafted.

In addition to steel losses from reduced efficiency, strikes still are taking their toll of tonnage. An outlaw dispute at the Duquesne Works of the Carnegie-Illinois Steel Corp. caused the loss of about 4000 tons of ingots, while a six-day wildcat strike at the American Works of American Steel & Wire Co. cost about 2400 tons of production. Another strike occurred at Andrews Steel Co.

Perhaps occasioned by the WLB steel wage case, which will have an important bearing on costs and prices, there has been delay in OPA's announcement of carbon steel price adjustments. Several weeks more may be required before the results come out. Meanwhile, the complicated alloy steel price study is going ahead, with cost data questionnaires being circulated. OPA last week received the Lake Superior iron ore industry's formal price proposal, with quick action urged.

Other developments: The sharp warning by Undersecretary of War Patterson against undue timidity by contracting officers in making termination settlements; interpretations of five sections of the new Renegotiation Act involving war contractors and relating to exemptions under the act; WPB's reductions in magnesium production at five plants; the Warner & Swasey suit to obtain a ruling on whether an amendment to the renegotiation act is retroactive.

TIGHTER than ever is the flat rolled steel production situation, by reason of the shell container program and the enlarged landing mat requirements of the armed forces. The concrete bar business has received a shot in the arm for the second quarter through a step-up in lend-lease and FEA business. Producers total orders in February at 45,000 tons were about 30,000 tons higher than in the same month last year. A Chicago contractor has received an order for 100 concrete barges for inland waterways usage, each requiring about eight tons of reinforcing steel.

Steel Market Briefs

• PRODUCTION—May have reached its peak, due to manpower situation. Repairs taking longer. If this gets worse, percentage of idle equipment will increase.

• BACKLOGS—Despite cancellations, cutbacks, etc., incoming orders have been ahead of shipments. Total backlogs have not been whittled down. Backlogs on some products are lower, others are higher. Plate carryovers are increasing, which tends to expand backlogs. Same situation present in sheets.

• CANCELLATIONS—Heavy with some companies, light with others. Not too significant, because of reorders later. Battlefield lessons will determine the cancelling out of some items, reorders of others. Considerable instability on cancellation trends expected.

• FLAT ROLLED—Relaxation on plates still expected by first of third quarter. Before that time, production pressure will be terrific, and magnified by manpower shortage. By the end of second quarter, plates, tin plate, and sheets expected to compete heavily for available rolling space. Sheet demands for shell containers and landing mats being telescoped into the first three quarters. Plate decline will be offset in third quarter because of this.

• ALLOY—Orders including NE grades more active, because of relaxation for use in road machines, hand tools, etc.

• PIPE—Demand strong for military needs, oil industry, and pipe lines.

• DELIVERIES—July and August on cold rolled sheets, October and later on hot rolled, September on strip mill plates, with October and November on wide plates. The foregoing are average deliveries, all subject to future developments.

the 825,000 ton directives, are expected to materialize completely for second quarter. Electrolytic mill schedules are rapidly filling for second quarter and some companies are receiving good tonnage for their bonderizing or chemically treated lines. As pointed out previously, electrolytic output this year is expected to be 20 to 25 per cent of total tin mill production, which also includes production of black plate.

One large tin mill product maker's production of electrolytic plate during the first three months of this year was about half as much as the output of coke tin plate, and accounted for around one quarter of total production of all tin mill products.

Production of beer cans will be heavy in second and third quarters, with about 95,000 tons of materials ordered for that purpose.

In order to distribute surplus aircraft materials more efficiently, a proposal has been formulated by officers at Wright Field, Dayton, that calls for the establishing of centralized depots where the goods can be inspected, classified, packaged, and otherwise put in first class shape for prompt sale. It is believed that such a plan can be worked out within the framework of the new Surplus War Property Administration.

THIS week's ingot rate continues unchanged at 97 per cent of capacity. District gains occurred at Detroit, up four and a half points to 101 per cent; in the Western area, up six and a half to 90.5 per cent; and at St. Louis, up three and a half to 96 per cent. Offsetting these are the losses at Pittsburgh, down half a point to 95.5 per cent; Wheeling, down two to 97; Cincinnati, down 15 to 81 per cent; and the Eastern District, down 16 to 90.5 per cent. All other steel producing centers continue operations at last week's levels. These include: Chicago, 101; Youngstown, 98; Cleveland, 99.5; Buffalo, 104.5; and Birmingham, 99 per cent.

Steel Industry Warned That 5 to 10 Per Cent Loss in Manpower Is Near Due to Draft

• • • **Unless he** is an "Einstein or an Edison" no steelworker or other steel company employee under 26 years old stands a chance of having his deferment renewed under the new draft policy recently established by the high command.

Steel industry leaders were told this on March 16 at a meeting of the Steel Industry Advisory Committee by Maj. Gen. Louis B. Hershey, WPB Chairman Donald M. Nelson and Executive Vice-Chairman Charles E. Wilson.

At the same time, the industry was told that older men in key jobs would be spared so far as is possible. It is estimated that the steel industry will lose 5 to 10 per cent of its working force under the decision.

Chairman Nelson told the group that the Army has decided that young deferred workers in industry must be drafted to maintain fighting-age-level of combat troops and has made the decision knowing that production losses may result. Mr. Nelson declared that he wouldn't say that a production loss would result from the decision and hoped that since industry has so far succeeded in conquering every production hurdle it would be able to jump this one too, and maintain high production rates.

According to Selective Service statistics, 465,000 men in industry and agriculture will be drafted and only 40,000 to 50,000 out of twice this number deferred will have their deferments continued.

Men in critical jobs in such programs as the B-29 and B-17 bomber programs can be retained, as well as men in the bearing, engine and other critical component industries.

Opinion is divided at WPB on the likelihood of a decrease of the operating rate in the steel industry and a production slump in steel-consuming industries.

While nothing authoritative is available, the most logical view is that military production cuts already planned (the Army has $1,500,000,000 in cancellations monthly scheduled for the first six months of the year) will balance the manpower loss.

Another result of the decision is the probability that orders relaxing metal controls will be held up for awhile and the date of Reconversion Day is more uncertain than ever.

Mr. Wilson announced to the committee the resignation of Steel Division Director J. T. Whiting, who will resume his duties as president of the Alan Wood Steel Co. The company has urgently requested Mr. Whiting's return, Mr. Wilson said.

Mr. Wilson pointed out that when Mr. Whiting came to WPB it was for a stated period. He has patriotically overstayed the limit.

Norman W. Foy, deputy director to Mr. Whiting, and Republic Steel Corp. executive, will become director. Mr. Foy has been with the Steel Division for more than two years.

Assistant Director Jesse Honeycutt, who has been in charge of the production branch of the Steel Division is also resigning to resume his post as vice-president in charge of sales of the Bethlehem Steel Co.

Many steel company executives expressed concern over the consequences of losing additional men. Reports were submitted which revealed that production is already falling off because of labor shortages, and with the arrival of warm weather, more production loss would occur.

One firm said that it anticipated a shortage of 11,000 workers, although already employing 15,000 women. In this plant thousands of men are working 16 hr. shifts, obviously a condition which can't keep up much longer.

Industry members indicated that there are now 42,000 fewer men working in steel plants than two months ago, and that the decline is accelerating. To conserve manpower after the heavy inductions of the next few months, committees may be set up on local levels to work with industry toward surveying the needs of each plant and making recommendations to local draft boards for those deferments that are absolutely essential to the continued operation. Membership on the committees would include representatives from the Army, Navy, Maritime Commission, WMC and WPB.

•

Cleveland

• • • **The concensus** of industrialists here seems to indicate that war production might suffer a reduction of from 10 to 60 per cent, based upon present war order volume, if current selective service withdrawals continue. Industry is pressing for a clear-cut policy covering draft withdrawals. A military source states that a new national draft policy is in the making.

The wide variance in the

NEWS OF INDUSTRY

From U. S. Steel's Annual Report, Page 142

estimates of production drop which may result from draft inroads is due to the widely varying conditions, within individual organizations and differing draft board tactics. According to some authorities, the figure of 60 per cent is an overstatement, but some reduction is certain.

One major steel producer reports that it has already lost 30 per cent of its force through the draft and that another four per cent are in the 18-26 year age bracket. The company reports that the present depletion has "already resulted in a large reduction in potential steel output" and "by midsummer this loss will run in excess of 113,000 tons per month."

A machine tool builder now mainly engaged in sub-contract work stated that about 15 per cent of his force would go under the present draft regulations within the next 90 days and that production could not be sustained above 85 or 90 per cent of present.

Another sub-contractor here reports a drop from 5500 men to 3200 to date and expects production to drop 15 per cent on an overall basis with individual departments being cut from 30 to 60 per cent within the next 90 days.

The aircraft industry is expected to be hit hard, according to a military source here, who reported that approximately 40 per cent of the aircraft industry's engineers are 26 and under.

Bill Jack, president of Jack & Heintz, said that 20 per cent of his forces were 26 or under and that production could drop 25 per cent or more depending upon which men were taken.

Chicago Mills Expect to Suffer

Chicago

• • • **Steel production** in the Chicago district, already reduced by labor shortages, will reflect immediately the draft of able bodied men under 26, a canvass of mills showed. In terms of steel deliveries, this means that delivery of such critical items as sheets and plates, now scheduled for Fall, will be delayed until well into 1945.

Steel has been named as one of the industries responsible for Chicago's recent classification as a Group I labor shortage area. The effect of increased draft calls in the "under 26" group will be particularly severe in skilled classifications heretofore shielded by Manning tables. The skilled classifications will be placed in the same category as unskilled is now —severe shortage and no available replacements. One major district mill frankly states that, not taking into account the probability of increased withdrawals by the draft, if its current rate of quits continues certain departments will have to be shut down by July for lack of crews. This same mill now is operating two 12-hour turns daily on some operations, and the industry generally has resorted to 10-hour work periods on critical jobs. The six-day week also is usual.

Past experience indicates that warm summer weather makes lengthened work periods physically impossible. Increased absenteeism throughout the plants may be expected to materially decrease the man-hours worked in proportion to the number of employees on the payroll.

Shortages of labor already has resulted in loss of substantial tonnage through inability to accomplish such routine tasks as roll changes and furnace repairs in the time normally required. Open hearth repairs formerly performed in about 10 days now are being made in 21 or 22 days.

One company estimates its ingot tonnage loss in this district because of repair lags at 7000 tons per month. Another smaller mill places its loss on this account at 5000 tons per month.

Attempts to recruit labor in cooperation with the War Manpower Commission have been fruitless. Because of the degree of physical fitness required for most mill jobs, draft of all physically fit men in the younger age bracket will tend to be out of proportion in comparison with industry and commerce as a whole. Carnegie-Illinois, now about 1800 employees below its optimum, has about 1500 men vulnerable in the "under 26" draft out of a total employment approximating 40,000. The Gary mill alone numbers about 1100 men in the "under 26" group.

The immediacy with which further withdrawals will hit production is indicated by the statement last week of a Moline firm that it was giving up its sizable shell forging contract because of inability to get labor.

Three Point Veteran Employment Plan

Chicago

• • • **Re-employment and** training of International Harvester Co. employees discharged from the armed services will take place under a comprehensive program affecting the company's 21 manufacturing and raw materials operations and its 187 sales branches and sub-branches in the United States. More than 15,000 employees now are in the armed forces.

Every company operation will have its own employment, placement, and training program for veterans, under the broad control of personnel and training departments at the main offices here. At each plant, the industrial relations manager under the supervision of the plant superintendent will direct the plan; at each branch house, the branch manager will take charge.

After an initial interview and a physical examination the veterans will be divided into three groups, with the following recommendations: 1—That the employee be returned to work without restrictions; 2—That the employee be placed according to job groupings developed by an occupational survey; and 3—That the employee requires special consideration for plant training or outside vocational training. Thus, each employee will find waiting for him some available position, or be offered special training or other preparation designed to prepare him for eventual employment.

Salvagers Select Officers

• • • **At the annual** meeting of the Salvagers and Re-Distributors Association, Inc., held on March 10, the following officers were elected: Abraham M. Hernowitz, Eastern Metal Co., Newark, N. J., president; Maury Cohen, Harry Harris, Inc., Kearny, N. J., vice president; Joseph B. Brown, Erie Steel Co., Philadelphia, secretary; and William Fabrikant, Julian Steel Products, New York, treasurer. M. Rosoff is counsel to the association.

WLB Decides to Hear 17c. Per Hour Testimony in Steel Wage Controversy

Washington

• • • **Split by internal** fights between CIO and AFL members, the War Labor Board on Tuesday was expected to authorize hearings beginning March 22 on the 17c. an hour wage issue despite the fact that a week previously public and industry members of the board had refused to permit AFL to attack the Little Steel Formula.

Already 94 companies, most in the steel producing industry and others in the casting industry, had been designated by WLB as properly in USWA's case before the board. This decision was made on March 18.

The steel companies had insisted that WLB has no jurisdiction over this issue and are far from satisfied with the decision that the board has the power to hear a case involving abrogation of the National Stabilization Program.

While the board and panel will hear the union's demand, the final decision in the last analysis rests with the President instead of the board. The whole country recognizes CIO's attempt to expand and increase the pay-off of the Little Steel Formula as a political issue. The country is waiting to see whether CIO President Philip Murray will be as successful as his rival, John L. Lewis, in further smashing war economic controls.

Through parts of last Thursday, Friday, Monday, and Tuesday the National War Labor Board debated over whether its Steel Panel should hear arguments of the USWA on the 17c. per hour demand.

Observers believed the difficulty arose because the American Federation of Labor's and Congress of Industrial Organizations members of the board's labor groups could not agree. Only a few days ago the board voted down a Federation request to ask President Roosevelt to modify the Little Steel Formula in a "realistic" way so that higher wages would be permitted. This, it is said, left the AFL smarting under the rebuff and in no mood to grant concessions to the CIO.

William H. Davis, WLB chairman, was present Monday and there was at least one other new face among the "public" members. Three of the industry group took the places of others who sat on Friday, and one of the CIO members of the labor group was a new figure.

The USWA-CIO has chopped 10 issues off its 24 demands. As the USWA case against the steel industry now stands, the following points are before the War Labor Board's Steel Panel:

1—General wage adjustment of 17c. per hr. for all employees.

2—Rehabilitation fund for steel workers in the armed services: $20 to be contributed by each steel-worker in the industry from wage increase directed by WLB and this amount to be matched by each steel company for each employee.

3—Guaranteed minimum weekly wage computed on employees' straight time average hourly rate for a year preceding the contract, plus the new wage adjustments, multiplied by 40.

4—Vacation with pay, one to two weeks depending upon length of service of employee.

5—Severance pay upon permanent closure of plant, to be based on four weeks' pay for more than one and less than three years' service, eight weeks' pay for employees with more than three years' continuous service.

6—Sick leave with pay, based on length of service.

7—Shift differentials amounting to 5c. per hr. for afternoon shift and 10c. for night shift.

8—Six holidays specified, with provisions that employees working on those days be paid time and one-half without reference to the present national emergency.

9—Elimination of geographical wage differentials.

10—Any wage inequality to be made subject of a grievance barring settlement of which may be submitted to the War Labor Board.

11—Classification of mechanical occupations, with fixed rates established for each classification up to three.

12—Provision for deduction of increased dues.

13—Common labor rate for learners.

14—Institution and maintenance by the company of a group insurance plan to provide life and accident insurance in a face amount equal to 75 per cent of the employees' average annual earnings with minimum coverage of $1,500, together with disability, hospital, and surgical benefits.

The other 10 points are being referred to collective bargaining, and the foregoing issues are opposed by the companies.

Meanwhile, the United States Steel Corp. has made the following counter-proposals:

1—WLB has no jurisdiction to consider a 17c. per hr. wage increase because the award of increases would be in violation to the national stabilization policy.

2—That the corporation will not voluntarily include the maintenance of membership and check-off provisions in a new contract.

3—Inclusion of wage scale in labor agreement, setting forth hourly and incentive wage rates.

4—No elimination of geographical wage differentials.

5—Elimination of inequalities of wage rates within geographical areas shall neither increase nor decrease total payroll for the plant. This means that some inequalities may be caused by too high an hourly rate for particular jobs and others by too low an hourly rate. Pay boosts for one class of workers would be reflected in pay decreases to others.

6—The new agreement should contain a procedure for adjusting alleged inequalities in both hourly and incentive rates and a procedure for establishing new and changed rates arising out of changed conditions.

7—No requirement shall be imposed on the companies for the payment of overtime rates beyond that required by law or applicable executive orders.

8—A mutually satisfactory permanent impartial umpire shall be appointed to serve for the life of the new labor agreement. The umpire's powers and functions shall be specifically defined in the agreement and his compensation and expenses shared by the parties.

9—Provision for penalties in the form of sanction and indemnities to be paid by unions in case of work stoppages, slow-downs, of interference appearing in violation of the agreement to discipline employees.

10—Agreed interpretations of the agreement should be arrived at by the corporation and the union to prevent so far as possible future misunderstandings.

Centralized Depots for Surplus Aircraft Materials Sought by Air Force

By S. H. BRAMS
Detroit Editor

• • • **An expanded program** for disposal of surplus aircraft material is taking definitive shape at Wright Field, Dayton, industry sources report. Indications from Washington are that the establishment of the new Surplus War Property Administration may shape its policies to utilize this framework for actual distribution of aircraft surpluses.

This Wright Field program is described as a down-to-earth method of procedure, rather than development of policies and principles which is being undertaken by the SWPA. Equally important is the fact that it is designed to make full use of long established and specialized industrial distribution systems in preference to superimposing on those systems a new Army-created program. For this logical and desired approach, industry can thank the chief of the Materials Distribution Branch at Wright Field, Lt. Col. A. E. R. Peterka, who, before going into service in mid-1942, was an executive of the Lamson & Sessions Co., Cleveland.

In brief, the program contemplates distribution of surplus materials by gathering them at centralized depots from which they will be filtered out through industry-operated warehouses, or, if possible, directly from contractors' plants to the warehouse distributors. Different channels would be established for steel, aluminum, copper, aircraft hardware, certain aircraft components and whatever else may be assigned to the Materials Branch for handling.

Efforts are being made by Col. Peterka to put this program into high gear while aircraft production is increasing. "If we can dispose of our surpluses by redistribution as they accumulate," he has said, "our problems later will be reduced." Accordingly, he has been in close contact in recent weeks with not only top executives of the steel and aluminum industries, but also with representative warehouse people and with the various Aircraft Councils.

Reaction of these groups has been good, but in some instances the implementation of oral arrangements by written commitments is not yet forthcoming. This is puzzling to some of the participants in these conferences. One asks, "Doesn't industry understand that this is largely their problem? Every day that goes by builds the surpluses a little larger."

Generally, however, industry agrees on the soundness of the ideas. From the viewpoint of company people, the prime obstacle to their adoption is the existence of various limitation orders which must be relaxed before the general program can be consummated.

The size of the surpluses, meanwhile, is as much a mystery as Mussolini's whereabouts. Estimates have been made, but they are only shots in the dark. Col. Peterka points out that companies which themselves hold surpluses often do not know the size of them, and hence efforts to set aggregate figures in any category are purely guesswork. The reasons for this are obvious and simple—mainly they stem from the fact that aircraft companies have been concerned with production, not in keeping records, and their inventories are not up-to-date, largely because of shortages of help. Ample proof of this is seen in Air Forces experiences in the past in obtaining lists of supposedly surplus stocks. In one case, for example, one of the largest plane producers reported approximately a million pounds of aluminum sheet and tubing as surplus, available for sale. When this was ordered picked up, only a third of that amount proved to be on hand.

This much is known, however: materials transferred thus far indicate a very substantial store of surpluses. Further, the transferral of surpluses, while relatively small today, is steadily increasing. Since last September, when this program began, approximately 6,000,000 ft. of steel tubing have been shunted from one contractor to another. About 9,500,000 ft. of aluminum tubing have been so shifted. Redistributed aluminum in other shapes aggregates more than 27,000,000 lb. More than 400,000,000 pieces of aircraft hardware, excluding rivets—"hardware" including fastening materials such as bolts, screws and nuts—have been transferred from one contractor to another.

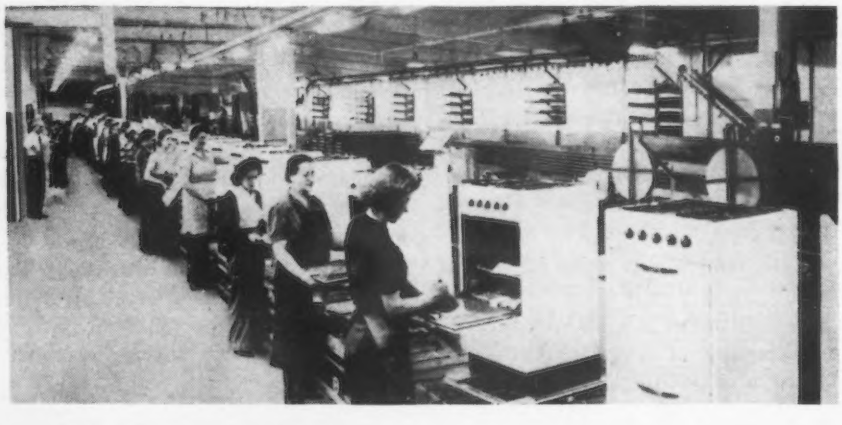
Getting down to cases, the detailed methods of disposal of surpluses differ with each material, following in general the accepted procedure of the industry involved. Distribution of aircraft hardware is through official aircraft hardware warehouses, selected by an aircraft industry vote and including the Aircraft Hardware Mfg. Co., Bronx, N. Y., and Supply Division, Inc., St. Louis, Mo. The third was in Los Angeles, but this contract has been cancelled by mutual consent and a successor is now being chosen.

Originally these warehouses were set up to supply small quantities of critical requirements, and their inventories were guaranteed against loss. Sales were at current market prices, and a customary handling profit was allowed. Gradually they have been working also into the redistribution of surpluses, but this has brought new problems which are now in process of solution.

One such problem has been the enlarged inventories which grow out of surplus material handling. The Procurement Division has recommended that the present guarantee for each of these warehouses be increased. Further, some method must be worked out to guarantee these warehouses against losses due to drops in market prices.

To illustrate, quotations on aircraft

KITCHEN RANGES: *Steel and rockwool insulated gas ranges are beginning to pour off the production line of a Borg Warner Corp., Norge division, plant at Muskegon Heights, Mich. These are not the Victory models, but first quality, pre-war types.*



hardware have declined an estimated 20 per cent in the past six months. With surplus materials coming into warehouses at going prices less commission, and moving out at the going prices, these outlets are definitely feeling a pinch today as market quotations crumble under them.

Some feel that the logical solution of this problem would be the consigning of goods by the Army to these warehouses, to be listed as sold only when they are moved out of the warehouse. However, service regulations call for the setting of a specific price at the time of transfer, and thus far the Army legal departments have been unable to work around this simple, but evidently quite formidable, stumbling block.

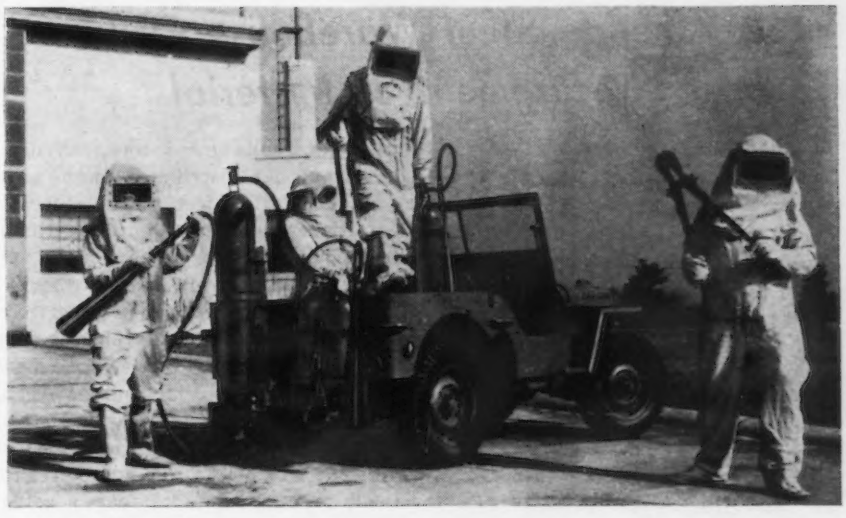
Another problem in connection with surplus disposal is that of inspection. Wright Field hopes to solve this by putting a resident Army or Navy officer at each warehouse.

Any materials coming to these warehouses under the expanded program would be checked periodically. Hardware in stock for a stated period, longer than normal under poorer-than-average conditions, would be ordered scrapped and would go to a melter. This would eliminate clogging of the warehouses.

Aluminum redistribution involves somewhat different procedure. Discussions have been held with Aluminum Co. of America and Reynolds on a cooperative program for moving surplus sheet, tubing, wire, rod and bar. This program, not yet finalized, would have Alcoa and Reynolds filing copies of their orders received with the Aircraft Scheduling Unit at Wright Field, which would in turn check them against inventories of surpluses. Should this screening establish that shipments can be made from surplus, the supplier company and the ordering firm would be so notified, and movement of goods from surplus would follow.

Commercial warehouse distributors would handle the actual redistribution. They would obtain the stock from government storage reservoirs or directly from contractors. Customary jobber discounts would be paid the commercial warehousers.

Aircraft steel redistribution is now being discussed by a committee including Col. Peterka for Wright Field and industry representatives as follows: Lester Brion of Peter A. Frasse & Co., Inc., New York; A. O. Fulton of Wheelock, Lovejoy & Co., Cambridge, Mass.; A. Y. Sawyer of Joseph T. Ryerson & Son, Inc., Chicago; G. L. Stewart of Edgar T. Ward's Sons Co., Pittsburgh; G. L. Tillson of Edgcomb Steel Corp., Hillside, N. J.; Walter S. Tower of the A. I. S. I.; and Walter S. Doxsey, president, American Steel Warehouse Assn., who is acting as committee chairman.



JEEP FIRETRUCK: *Equipped with three 15 lb. and one 75 lb. Kidde units with long hose, big nozzle and auxiliary tools, the Coast Guard jeep is converted into a highly mobile and well equipped firetruck for combating airport, dock, or other localized inflagrations. Asbestos suits protect firefighters from intense heat.*

The line of arrangements being made calls for setting up in specific detail the kinds and quantities of steel which will and will not be redistributed, together with minimum weights and sizes. Working from this pattern, the Army Air Forces would separate material to be scrapped, this to be undertaken in contractor plants or government reservoirs, and the remainder would move into warehousing channels where standard industrial procedure and standard fees would be paid. All pricing would be on a basis permitting selling of steel at published levels for warehouse or mill quantities.

At present 26 official aircraft steel warehouses are designated as handlers of critical aircraft quality steels in warehouse quantities, and these are being thought of as a nucleus for the proposed redistribution enlargement.

Copper and brass distribution presents hardly any problem at all in aircraft. Through the industry itself, the WPB Copper Division and the Copper Unit of the Materials Distribution Branch at Wright Field, surplus brass and copper products are being handled about as rapidly as they are unearthed.

Steel Warehouses' Aid Is Sought

Cleveland

• • • **The prime steel** warehouses of the nation are reported being asked by the Army Air Corps to assist in the redistribution of from 50,000 to 200,000 tons of idle and excess aircraft quality steels. This comparatively large estimated tonnage is piled up in inventories of the major aircraft producers as a result of changeovers and completion of contracts. Redistribution of the material represents a problem as it can only return to the aircraft industry from which it originated. Also the warehouse industry is not entirely suited to handling the material in the lots in which it is offered.

Greatest problem presented to the warehouses by this request is the stocking of individual lots of from several hundred tons to 1000 tons which are being offered and which the Air Corps is reluctant to break down in smaller lots. Also the prime warehouses are not well equipped to sort out the various items of a lot and do the reconditioning required as they have never been set up for such operations.

Although the warehouses may have some difficulty in handling the stocks, their use as a clearing house to keep the records straight and get the steel back into usuable condition is believed the ideal solution. No monetary risk in involved for the warehouses as the steel is expected to remain the property of the Air Corps.

WPB Amends Steel Warehouse Orders To Ease Procurement of Material

Washington

• • • **Amendments to orders** M-21-b-1 and M-21-b-2 dealing with restrictions placed upon business handled by steel warehouses and merchants of steel products have been made. These orders were planned to replace controlled materials allotments which had been ordered from the warehouses, but made it difficult for steel fabricators or other new firms to get into the business.

Under the amendments, warehouses will be authorized to place orders with producers to replace stocks. Also, they may obtain idle, excess, or salvage steel. Mills may accept additional orders from warehouses but can fill them only if the mills have excess capacity for so doing. A warehouse order placed with a producer or a holder of excess stocks will be considered an authorized controlled material order. Provisions are made in the amendments for establishing initial stocks of a warehouse for concerns not previously authorized to act as distributors of general steel products; for distributors wishing to purchase for stock a product group that was not previously handled; and for distributors who have not previously purchased general steel products from producers but now wish to do so.

As to merchant stocks, a distributor may purchase from a producer only for replacement, and may order from another distributor in the same manner and subject to the same restrictions as when he purchases from a producer. Also, a distributor may order for stock from another distributor any merchant trade product items which the latter has purchased from idle or excess inventories or has salvaged from material purchased as scrap. Such material doesn't have to be to support such an order. Lastly, a distributor may order any merchant trade product for stock from a holder of idle or excess inventories on a "special sale" as provided in Priorities Regulation No. 13.

A merchant steel distributor may place orders with any producer, which will be filled after the producer has filled all tonnages reserved for controlled material allotments. To take advantage of any reserved tonnage, a distributor must submit his orders to the producer then holding his base tonnage not later than the expiration date stated in the warehouse load directive. A producer may fill a distributor's order for that quarter received after the expiration date but may not reserve any space for such orders.

A. S. & W. Concentrates Rod Output

Chicago

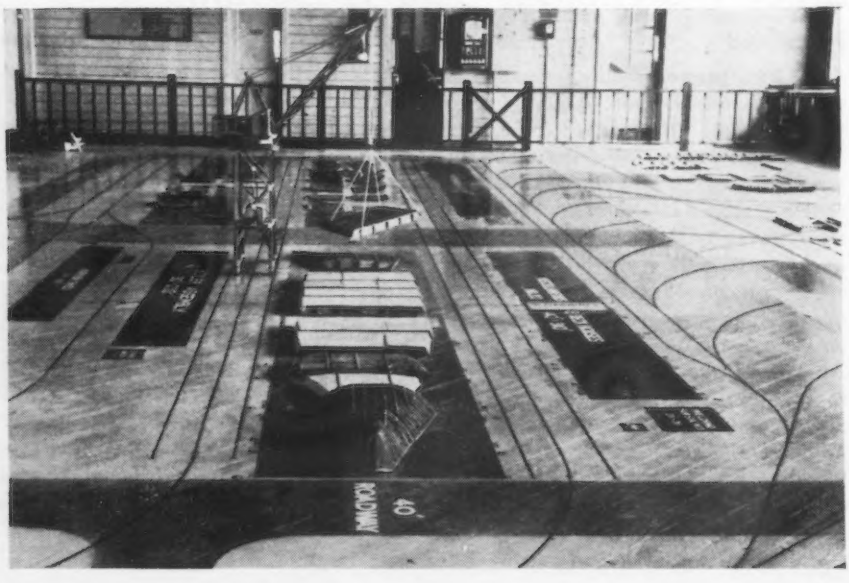
• • • **Wire rod** production facilities at the Waukegan works of the American Steel & Wire Co., Waukegan, Ill., are being dismantled, and the company's wire rod production in the district henceforth will be concentrated at its new Collins Street plant, Joliet.

One rod mill at Joliet was dismantled in 1937, and two mills are being junked in the present program. Wire rod capacity at Waukegan, which now will be eliminated, amounts to 155,000 gross tons annually, according to latest available listings.

The company recently completed a modernization program at Waukegan with view to devoting that plant entirely to production of finished manufacturers' wire in peace time. Rod patenting equipment has been replaced and relocated, heat treating equipment replaced, straightening and cutting and tinning equipment replaced and relocated, additional continuous wire drawing and finishing equipment installed, the spring mill improved, with several equipment replacements, cleaning house and iron sulphate facilities replaced, rod storage and warehouse space extended, and office facilities modernized.

Fragmentation bombs currently are being produced. Wire products which will continue to be made at the Waukegan plant include bolts, nuts, spring wire, bale ties, manufacturers' wire, valve springs, music wire, oil-tempered wire, specialty wire, etc.

SCALE MODEL SHIPYARD: *This ½-in. scale model of the Bethlehem-Fairfield shipyard is used for the rehearsal of Victory Ship production. By studying the minature, efficient flow of materials and assembly on the ways can be worked out in advance of actual production.*

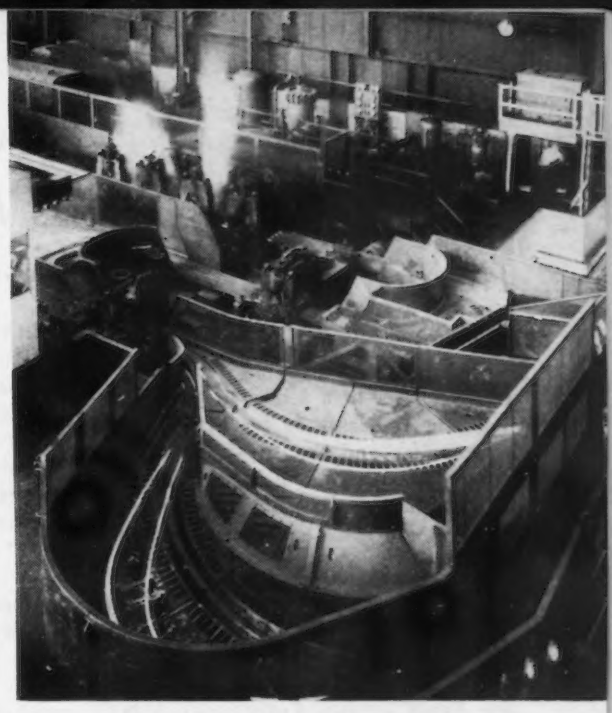


Two Divisions Created

Cleveland

• • • **American Steel & Wire Co.** is creating two separate divisions to handle the sale of electrical products and wire rope and construction materials. P. T. Coons, formerly head of the electrical, wire rope and construction materials department, which is being discontinued, will assume the responsibilities as manager of the wire rope and construction materials division. T. F. Peterson has been appointed manager of the newly created electrical division.

Merchant Wire Product Pattern Expected to Remain Liberal



Looping stands at a Bethlehem continuous rod mill

Pittsburgh

• • • **With the** exception of woven wire fence, which took a terrific dip in 1942, the general production pattern of merchant wire products changed very little in the period from 1939 to 1943. Despite this little change, in actual statistics, the possibly dry figures do indicate an excellent job on fulfilling agricultural requirements during 1942 and, especially, 1943. Credit for this achievement goes to the combined cooperation of the steel, farm, and WPB groups.

Production of nails and staples, as well as twisted and barbed wire, was exceptionally heavy in 1942, due, apparently, to military construction and some bulding up of stocks for military purposes. This was superimposed upon a WPB controlled demand from agricultural interests. Also significant, from the standpoint of reflecting the importance of certain farm products, was the exceptionally high level of bale tie production in 1942 and in 1943. The emphasis on this product, and the tying in of directives consistent with the demand, made it possible for the agricultural industry to utilize to the fullest extent baled hay, etc.

Indications are that 1944 will see just as liberal a merchant wire product pattern as last year, especially in view of the continued importance of the food and feed program during the course of the war. It is expected that any bad effects, which resulted from the virtual cessation of woven wire fence production during at least six months in 1942, will be overcome this year. Governmental officials, as well as others, apparently learned last year that such items as woven wire fence, bale ties, etc., have a direct bearing upon the amount of feed, meat, and other food, which may become available for general consumption. The lack of some of these items, at one time, threatened many farmers with a conglomeration of pigs, cattle, chickens, etc., meeting and eating upon common ground. A much better separation appears to have taken place during the past six months.

On the industrial wire front, as expected, drawn wire production advanced quite rapidly in tonnage from 1939 to 1943. In the latter year, production was about 44 per cent ahead of 1939. There is every indication that the same pattern will probably prevail this year for this product. While military demands may not have completely made up for the tonnage which originally went to the automobile industry before the conversion, the statistics for 1943 indicate that drawn wire output was not far from the unprecedented production in the year 1941.

The production of wire rods in 1943 was about 77 per cent greater than in 1939. This represents wire rods which were sold as such, and were not shipped within the steel industry for further processing into wire. This increase in wire rod output compares favorably with the 78 per cent increase in all finished steel products, from 1939 to 1943. This expansion was to be expected, in view of the varied and miscellaneous uses for wire rods in the war effort.

In considering total production of wire rods, drawn wire, and merchant wire products, the increase of this total production in 1943, compared to 1939, amounted to about 39 per cent. Summarizing, on an individual basis, wire rods were up 77 per cent, drawn wire 44 per cent, and merchant wire products 32 per cent in 1943, as compared with 1939. During that period, it is also probably significant that much standardization, with elimination of a great number of specific types or sizes of merchant wire products, was effected, and the benefits of these simplifications, it is hoped by many in the industry, will hold in the postwar period.

TRENDS IN WIRE MILL PRODUCTION FOR SALE

1939-1943. Net Tons. 000 Omitted.

Patterson Flays Officers for Timidity on Contract Termination

Washington

• • • **Undersecretary** of War Robert P. Patterson in a letter to the Commanding Generals of the Army Service Forces and the Air Forces blistered the delaying policies of War Department contracting officers in making contract termination settlements.

The letter, dated Feb. 10, but made public March 15, said:

"Termination procedures established in the contracting offices of the Army Service Forces and Army Air Forces have not produced expected results. The reluctance of contracting officers to execute courageously their responsibilities as outlined in Procurement Regulation 15 continues to delay unnecessarily contract termination settlements. This reluctance is evidenced by the number of settlements awaiting contracting officer's approval as to disposition of contractor-owned property or as to contractor's statements of charges.

"* * * It is the policy of the War Department definitely stated in Procurement Regulation 15, that the contractor receive fair and reasonable compensation for work performed and for the supplies and articles furnished under the terminated contract.

"In this respect the work of the contracting officers will be evaluated not by the extent to which they succeed in reducing the settlements proposed, but by the extent to which prompt settlements are fair to both the contractor and to the government, are made.

"The delay in approving contractor's statements of charges results not only from improper preparation of statements but also from the unreasonable utilization of detailed auditing. Reluctance to make use of the office review procedure and an insistence on field audits have delayed settlements for extended periods.

"It is important that office reviews of the scope outlined in Procurement Regulation 15 be utilized to the fullest extent and that field audits be the exception rather than the rule.

"Contracting officers should bear in mind that in submitting statements to the Government, the contractor represents the facts stated are true and he is subject to penalty for any false certificate. * * *"

Warner & Swasey Asks Ruling on Renegotiation Law Amendment

Washington

• • • **The Warner & Swasey** Co., Cleveland, filed suit in the District Court of the United States for the District of Columbia March 18 under the Federal Declaratory Judgment Act to obtain a judicial ruling as to the proper construction of an amendment to the renegotiation law.

"The original renegotiation law, which went into effect as of April 28, 1942," L. B. McDonald, vice president of the company, said in commenting on the suit, "did not include sales to the DPC as subject to renegotiation.

"Over a year later—effective as of July 1, 1943—Congress amended the renegotiation law so as to include for the first time DPC business; and this provision has been interpreted by the services as being retroactive to April 28, 1942. The question we want the Court to decide is whether or not Congress intended to make this provision retroactive, and if so, whether or not the retroactive feature is constitutional.

"At the time of our original renegotiation it was our assumption that this concluded renegotiation on our 1942 business. Then in July, 1943, Congress passed the amendment making sales to DPC renegotiable, and we have been told that retroactive renegotiation of our 1942 DPC business is necessary.

"It should be borne in mind that we are not seeking to enjoin the government in this action, nor are we questioning in this suit the constitutionality of the renegotiation statute as a whole. We have simply asked the Court, by means of a declaratory judgment, to define our rights in the matter."

Producers and Fabricators Form Magnesium Association

Chicago

• • • **To assure the** future of magnesium alloys and to foster the development of fabrication techniques, producers and fabricators have formed *The Magnesium Association.* One of the purposes will be to give members and the public authentic information as to the properties and advantages of magnesium alloys, as well as to the suitable type of applications.

Edward S. Christiansen, vice-president of Apex Smelting Co., was elected president of the association at an organizational meeting held in Chicago. C. C. Loomis, president of the New England Lime Co. was elected vice-president, and C. E. Larson, operations manager of the White Metal Rolling & Stamping Co., was elected treasurer. Temporary offices are at 2537 W. Taylor Street, Chicago 12.

The membership of the association is representative of the magnesium industry in all of its phases. Four major groups are represented: producers and smelters of ingot; sand, permanent mold and die casters; wrought products; and magnesium powder manufacturers.

C.E.D. Issues Handbook On Planning for Postwar

New York

• • • **Concrete steps** that may be taken by industrial employers in planning for high postwar levels of production and employment are set forth in a handbook, "Planning the Future of Your Business," prepared for the Committee for Economic Development by a special committee of the Association of Consulting Management Engineers.

The six steps in postwar planning by individual businesses as formulated in the C.E.D. handbook for industrial employers are: 1—Define and place responsibility for postwar planning; 2—Plan product programs; 3—Plan market and sales programs; 4—Determine the manufacturing facilities required; 5—Estimate employment requirements, define jobs, and plan employee training; and 6—Estimate the operating funds needed and plan their sources.

The detailed suggestions made under these six headings emphasize the need of making postwar plans, concrete and realistic to those "down the line." Business executives are urged to subject their pricing policies to harsh scrutiny, since "postwar competition will demand it."

WPB Eases Orders on Civilian Goods But Manpower May Prove Obstacle

Washington

• • • **Easing of the** supply situation in metals has been reflected for some time in WPB orders which relax or remove restrictions on the use of such materials. These orders are growing in number and are being issued almost daily either singly or in groups. Whether or not the Army and Navy policy of tightening up on draft requirements will so affect production as to cut down the number of these orders remains to be seen. The general impression is that the military policy will not greatly affect the trend toward wider uses of metals for civilian and war purposes. One reason for this view is that it has been found that use of substitutes for metals often requires more manpower than is required in producing the metals.

Among recent WPB orders easing the metals supply situation are the following:

Casket manufacturers were permitted to use a total of 10 lb. of iron and steel per casket and 7 lb. per shipping case. The previous maximum for caskets was 3½ lb. for shipping cases and 5½ lb. for caskets.

Restrictions were removed on the use of metals in industrial type incandescent lighting fixtures and restrictions were relaxed on residential types of incandescent lighting fixtures.

Permission was given to produce extra heavy cast iron soil pipe. Production of this type of soil pipe had been prohibited since June 1, 1942. In the meantime only a single weight, "Victory weight" of cast iron pipe could be manufactured.

Restrictions were removed on the manufacture of barbed wire and woven wire fence.

Restrictions were lifted on the use of lead for counterweights and steel plates for battery boxes in industrial power trucks.

Restrictions were removed on the use of alloy steel in hand-operated wood and special purpose saws, and on the use of alloy steel in scrapers, angledozers, or trailers and bulldozers.

Permission was granted to increase production of bedsprings and box springs by 25 per cent and to improve their quality by using more steel per unit.

Standardization restrictions on the production of general purpose thermometers were removed. The complete restriction on the use of copper base alloy for industrial thermometer cases and case fronts was removed and permission given for use of a composition alloy up to 74 per cent copper and 1½ per cent tin.

Restrictions on the production of barbed wire and woven wire fence were removed because the necessity of these restrictions has passed and these products are in less demand for the direct war program. The revocation will permit the manufacture of heavier gages and a return to standards weights of zinc coating. WPB said that the heavier gages are needed to properly confine hogs and cattle and that the standard zinc coatings will result in lengthening the life of the product.

The permitted use of alloy steel in place of carbon steel in the manufacture of special purpose saws, WPB pointed out, is in line with its general policy to re-substitute materials formerly used when such a switch is indicated by the supply situation and involves no increase in the labor force. Alloy steel was customarily used for better grade saws before the restrictions were put into effect in September, 1942. It was this same policy that prompted the removal of restrictions on the use of alloy steel in road building machinery.

WPB Urges Return Of Excess Allotments

• • • **To assure maximum** production from the available supply of steel, copper, and aluminum, WPB urged that all consumers cooperate to the fullest possible extent in returning excess or unusable allotments. CMP Regulation No. 1, paragraphs (e) and (w), require that excess or unusable allotments be returned. As of the first of each month, and again at the end of the quarter, paragraph (w) users must determine if excess allotments have been made. The following factors may be considered:

1—Whether you have received excess or duplicate allotments in any one quarter; 2—Whether you can operate on smaller inventories than in the past; 3—Whether orders actually received are less than anticipated; and 4—Whether, for any other reason you will have excess or unusable allotments. If these periodic examinations disclose any excess, the excess must be returned as set forth in paragraph (w) (2) of CMP Regulation No. 1.

Allotments may be returned by letter or on form CMP-32, preferably the latter. The return should be made to the person, Claimant Agency or Industry Division from whom it was received. In those cases where the original allotment is clearly identifiable with a CMP-4B application which has been assigned to a WPB Field Office, the return of such allotment should be made to that Field Office.

Attention was called to the amended Direction No. 26 to CMP Regulation No. 1, which explains when allotments may be returned by a secondary consumer directly to a Claimant Agency or to the WPB, rather than to the person from whom the allotment was received.

Priority Changes

L-42—Sched. IV, as amended, gives permission to produce extra heavy cast iron soil pipe. (3-15-44)

L-49—Amended order gives permission to increase production of bedsprings and box springs by 25 per cent and to improve the quality of these items by using more steel per unit. (3-16-44)

L-64—Amended order permits casket manufacturers to use a total of 10 lb. of iron and steel per casket and 7 lb. per shipping case. (3-16-44)

L-157—Sched. III, as amended, removes restrictions on the use of alloy steel in hand-operated wood and special purpose saws. (3-16-44)

L-188—Amended order permits the use of zinc for applying a protective coating or plating for metal parts of binders (blank books, loose leaf books, or covers). (3-16-44)

L-211—Sched. III has been revoked, removing restrictions on the manufacture of barbed wire and woven wire fence. (3-16-44)

L-216—Sched. VI, as amended, removes restrictions on the use of alloy steel in the manufacture of vises. (3-18-44)

L-217—Sched. I, III, and IV have been revoked, removing restrictions on the use of alloy steel in scrapers, angledozers or trail-builders, and bulldozers. (3-17-44)

L-217—Sched. VI, as amended, removes restrictions on the use of metal for specified parts of truck mixer-agitators. (3-17-44)

L-264—Amended order permits use of brass in screw bases for rectifier tubes. (3-17-44)

L-267—Amended order relaxes slightly controls over production and distribution of restricted photographic equipment, accessories, and parts for non-military orders, to permit increased production of specified items and to facilitate distribution. (3-17-44)

L-272—Sched. VII, as amended, removes standardization restrictions on the production of general purpose thermometers by deleting them from the schedule. (3-17-44)

M-21-b-1—Amended order deals with the restraints placed upon business handled by steel warehouses. (3-16-44)

Greater Civilian Output Expected

Washington

• • • **Definite quality** improvement and in some instances increased production of some minor civilian goods can be expected by consumers in the next few months, the OWI reported on the basis of the WPB's revision of a number of limitation and conservation orders during the past few months. Any forecast, the WPB says, may be upset at any time by an unexpected turn in military events.

Civilian goods whose quality is being improved or whose production is being increased are those articles most frequently mentioned by consumers as "shortages which bother them," according to a recent survey made by WPB's Office of Civilian Requirements.

The only new items of civilian goods to be brought back into production this year, according to WPB, are: 1—Articles using comparatively small quantities of manpower and materials; 2—Those not interfering with war production; 3—Those not requiring extensive conversion of facilities; and 4—Those which would contribute more time and energy to war workers for their jobs.

There are no early prospects for the production of heavy durable consumers' goods such as automobiles, washing machines, mechanical refrigerators, vacuum cleaners or radios. Plant facilities as well as certain component parts and raw materials required to make these items continue to be needed for war production.

Electronic Idle Stock Plan Of Utilization Mapped

• • • **Progress in the** utilization of idle and excess stocks of electronic components in order to meet the greatly expanded military electronics program for 1944 is being accomplished through the components recovery program of the WPB Radio and Radar Division. To implement the program, the Radio and Radar Division recently organized a Component Recovery Section which provides a clearing house for the interchange of inventories of surplus radio and electronic components between the prime contractors, the Armed Services, and the Division. The basic plan is to return surplus components to the productive stream and thus smooth the flow of production of end equipment required in the greatly increased military electronics program this year.

Advantages that may be realized by the components recovery program include:

1—Through the use of idle and surplus inventory lists, electronics prime contractors may obtain needed components from idle and excess stocks of other contractors and also from the Armed Services.

2—Through WPB distribution of these stock lists to all contractors and the Armed Services, a prime contractor may transfer excess inventory stocks to other contractors and the Services.

3—Utilization of surplus component stocks will aid prime contractors in stepping up war production and help to insure prompt delivery of end equipment to the armed forces.

4—A prime contractor can arrange for the disposal of all remaining non-military stock items through the medium of WPB form 1161 (formerly PD-470).

5—The utilizing of components of his own manufacture, which have become idle or excess stocks in the hands of prime contractors through engineering changes or by cancellation or termination of contracts, will enable a component producer to complete his orders in time to meet schedules.

The Component Recovery Section receives idle and excess inventory lists resulting from cancellations, terminations, and changes in prime contracts, and also surplus inventory lists from the Armed Services and prime contractors. These lists are distributed to Army contracting officers, Army procurement districts, the Army-Navy Electronics Production Agency, the radio material and supply officers of the Navy, and to prime contractors requiring critical components.

Auto Advisory Committee To Meet with WPB in April

• • • **A WPB Automobile** Industry Advisory Committee composed of the top-ranking official in each company that manufactured passenger cars at the time production was frozen by government order is being formed. This committee will meet with WPB officials in April to explore the basic problems that must be dealt with by industry and government as a preliminary to the eventual resumption of passenger car production. Its purpose is entirely exploratory and advisory on the part of both industry and government.

In commenting on this committee, WPB chairman Donald M. Nelson emphasized that the calling of this meeting is not prompted by any plan or prospect of achieving resumption of passenger car production at any specified time that can now be determined. This conforms to WPB's previously stated policy that there can be no major reconversion of industry until the European war is won.

The coming meeting with the Automobile group is one of the most important of a series of meetings which is being held with leaders of various consumer goods industries and WPB officials to examine the problems that will arise when the time comes for the transition back to peacetime production. It is essential to make plans now so that when the proper time does come the transition from a war economy to peacetime production can be as smooth, as rapid, and as fair as possible.

Price Briefs

• Amdt. 7 to RPS 82 limits the maximum price for sales of wire, cable, and cable accessories by wholesalers and jobbers, to industrial, commercial and governmental purchasers to 120 per cent of the manufacturer's net price to wholesalers in the same quantities. (Release No. OPA-4060)

•

• Amdt. 106 to SR 14 permits mark-up for reconditioning on ceiling prices of used airplanes. (Release No. OPA-4055)

•

• Amdt. 110 to MPR 136 adds metal stampings to the list of articles covered by the regulation establishing maximum prices for machines and parts and machinery services. (Release No. OPA-T-1825)

Restrictions Removed on Barbed Wire Manufacture

• • • **The removal** of restrictions on the manufacture of barbed wire and woven wire fence was ordered by WPB. This action was taken by the revocation of schedule 3 to limitation order L-211, which stringently restricted the gages and types of wire fencing that could be produced.

The necessity for these restrictions has passed as the types of steel required for these products are not in as heavy demand for the direct war program. There will be practically no increase in manpower demands since this revocation will result chiefly in transfers of labor from one type of operation to another. At any rate, any increase in volume would result in very few additions to labor forces.

The revocation of this schedule will permit the manufacture of heavier gages and a return to standard weights of zinc coating. The heavier gages are needed to properly confine hogs and cattle and the standard zinc coatings will result in lengthening the life of the product.

Lend-Lease to Allied Nations Totals $19,986,000,000 Since March, '41

• • • **Total lend-lease** aid in the form of materials and services from the United States to Allied nations since the beginning of the program in March, 1941, through Dec. 31, 1943, amounted to $19,986,000,000, while aid during 1943 alone totaled $11,733,000,000. Actual lend-lease exports during this period have amounted to $15,578,000,000. Munitions made up the bulk, representing 54 per cent of total aid. The ratio was 22 per cent in 1941, 47 per cent in 1942, 62 per cent in 1943, and 67 per cent in December, 1943. Total lend-lease exports to the various recipient nations are shown in the accompanying table.

Meanwhile, lend-lease also works in reverse. Under this reverse lend-lease, recent requisitions to meet plane repair and adaptation needs of U. S. Air Forces abroad have been filled by the British without payment by the United States and include items as varied as 1,357,730 sq. ft. of steel and light alloy sheets and 235,000 rubber shock absorbers. U. S. Army Engineers in the United Kingdom have received as reverse lend-lease over 44,250,000 yards of steel landing mats, hundreds of miles of electric wiring, millions of spare parts for motorized equipment, and other such equipment. Likewise, 20 per cent of the food consumed in the United Kingdom by our forces is provided as reverse lend-lease; almost all tires for American Army trucks are supplied in this manner; and Australia has turned over to American forces fleets of trawlers, launches, ketches and small coastal steamers.

The Soviet Union has received about 27 per cent of the total lend-lease shipments, with lend-lease starting to Russia in October, 1941. Significant are the heavy imports of machinery by Russia as compared with other commodities and the machinery imports of other nations. Up to Jan. 1, 1944, some 177,000 tons of explosives to be used in the manufacture of bombs and shells in Soviet factories; 1,350,000 tons of steel; 384,000 tons of aluminum, copper, and other non-ferrous metals; 740,000 tons of aviation gasoline, lubricating oils, and petroleum products; and 145,000 tons of refinery equipment were received by Russia on lend-lease. In addition, planes (see THE IRON AGE, March 9, p. 76), tanks, munitions, foodstuffs, agricultural equipment, and seeds have been sent to Russia. During 1943, 99 per cent of the ships sailing with lend-lease supplies reached Russia safely, whereas in 1942, some 12 per cent of the ships were lost.

Shipments to the United Kingdom in 1943 were three times the 1942 total, but shipments of industrial materials and products and of food were up only 50 per cent. This indicates that fighting equipment made up the bulk of the increase. Thousands of planes, tanks, trucks, and other military motor vehicles were shipped to the United Kingdom. Some $460,000,000 worth of aircraft engines and parts; 4,800,000 tons of steel; 460,000 tons of non-ferrous metals; and large quantities of other raw materials and machine tools were lend-leased to the United Kingdom. Also, there were 125,000,000 barrels of petroleum products shipped, as well as 10 per cent of the British food supply. Fertilizer and farm machinery shipments have assisted the British in increasing domestic food production by 70 per cent over pre-war levels.

Of the 1943 lend-lease exports to the Africa, Middle East, and Mediterranean areas, 75 per cent were in the form of finished munitions, 17 per cent as industrial materials and products, and 7 per cent of agricultural products. The British and the French have been the major recipients of lend-lease aid in Africa, but it has also aided the Australians, Poles, Greeks, and other fighting units of United Nations forces in these areas. Many French army divisions have been equipped through lend-lease, as have French air squadrons and French Naval units. Vital civilian supplies to the people of French North and West Africa have been forthcoming through lend-lease. These supplies are now being paid for by the French authorities at full landed cost, and the United States has already received $62,250,000 under this plan.

Transportation, the greatest obstacle in aid to China, has been helped by the development of the air transport route into China. This system

has grown by leaps and bounds until in December, 1943, twice as much was shipped into China by air than during the entire year of 1942. In January, 1944, the tonnage of goods flown into China was 15 times that of January, 1943. However, the total aid to Dec. 31, 1943, amounted to only $200,995,000. In addition, goods valued at $191,731,000 have been consigned to the United States commanding general in the India-China theater for transfer to China.

Lend-lease to India to Dec. 31, 1943, totaled $849,452,000, the policy on which has been determined by the importance of India's strategic and geographic position in the Far Eastern war theater. India is the major supply center for the war against Japan, with the best network of railroads in Asia and the terminal for the China air supply route. India is the chief base for action against the Japanese in Burma, but is also a major source of strategic materials essential to the American war effort. India is becoming a great arsenal as well as a military base. It not only produces small arms and small arms ammunition, bombs, torpedoes, armored cars, ordnance carriers, machine guns, artillery ammunition, and other military items, but is rapidly developing its industrial possibilities. Lend-lease has provided some of India's requirements for machine tools and raw materials. Machine tools under lend-lease have been valued at $10,000,000, but currently India is buying all of its machine tools in the United States for cash.

Lend-lease is also supplying munitions aid, war production aid, and agricultural aid to other allied nations, including Australia, New Zealand, and the South and Central American countries. All of these nations have rendered valuable direct military aid. (Lend-lease aviation statistics were printed in this magazine March 9, page 76.)

Truman Manpower Report Examines Over-Hiring of Workers, Other Phases

• • • **Phases of** the voluminous third annual Truman Committee report, issued early this month, have been covered in this magazine March 9, pages 78-80 and 103; and March 16, pages 82-84. The problem of manpower shortages was one of the specific subjects examined in detail by the committee. Here are some of the committee's comments on labor hoarding and other aspects of the labor picture:

"The nation-wide supply and demand for manpower is roughly in balance. Total employment is expected to reach about 53,400,000 by July, 1944, including a peak force of 12,100,000 agricultural workers. The armed forces are expected to total 11,300,000. Unemployment will remain at approximately the present level of 1,000,000 and about 815,000 additional workers will be available for employment if they could be used in their particular localities. . . .

"The committee has discovered a widespread tendency on the part of employers to estimate manpower requirements on the basis of how many workers they could crowd into the plant rather than upon the basis of how many they can efficiently employ. This is on the theory that if enough workers are available at all times to do the maximum amount of work that may be required, production will be somewhat greater than could otherwise be obtained. . . .

"**A similar practice**, prevalent when material shortages were most acute, was that of ordering materials in greater quantities and at an earlier date than required. The availability of more labor and materials than can be used greatly reduces management problems and cushions the effects of mistakes of management in estimating actual requirements. . . .

"The War Manpower Commission has done some good work through the 1500 utilization studies that have been completed to date. For example, its study of the Seattle ship construction yards resulted in an order in October to reduce employment by 10 per cent. Other controls instituted in this area reduced turnover rates considerably. These reductions were achieved with no loss of production.

"However, programs of this kind are difficult to put into effect, and require more skillful and intelligent personnel than is readily available. Utilization studies also consume time.

"These programs are steps in the right direction, but at best are merely substitutes for direct and determined action by the procurement agencies and the industries themselves. They are much more familiar with their own operations and should be better able to find and eliminate inefficiency if they have the will to do so. Their search for inefficiency will be stimu-

COOLING OFF: *After some furious action against the Japs at Cape Gloucester, New Britain, this 75-mm. howitzer had to be cooled off and cleaned up by washing out the tube.*

lated if they know that they will not be given blank checks on manpower.

"**A blank check** on manpower had to be given to the military because the secrecy that necessarily enshrouds military strategy makes it undesirable to scrutinize the accuracy of the estimated requirements. There are doubtless many situations in the United States where men in the armed forces are not being efficiently utilized, but troop utilization is so closely allied to strategy that the committee believes that the estimates of the armed services as to their needs should be accepted so long as there is assurance that strategic plans have been made to utilize the men requested. The armed services have set up special procedures to check on efficiency of utilization and to reduce or eliminate military installations that are no longer fully useful. The success or failure of such policies can be evaluated only after the war, when the conclusions reached will be largely academic.

"However, a similar blank check on manpower cannot be given to the procurement agencies any more than they could be given a blank check on materials. They must be forced to utilize efficiently what is available, despite the temptation on the part of each one to argue that its needs are so important that any contribution to them however small is more important than any loss to other programs or to the civilian economy, however serious it may be.

"This argument has even been extended by some procurement officials to the extent of saying that there is a patriotic duty to reduce the civilian economy to bare levels of subsistence to bolster the morale of the men in the armed service.

"The committee disagrees with this argument. There is a patriotic duty to maintain a sound, healthy economy capable of waging a long war and of providing jobs for the armed forces when they return. Workers requested for war production should be made available and civilian production should be cut only to the extent that such workers are actually required and can be efficiently utilized. Enforced idleness of war workers is destructive to morale and increases the cost of the war, and there has been far too much of it.

"**These principles** were frequently disregarded, and it was a common practice for manufacturers to hire more workers than they could use or even train at the time of their employment. Complaints were received by the committee from every section of the country and involved most of the key war industries. The cost of such practices was borne by the Government and not by the manufacturers. This was true both where the agreements involved were cost-plus-fixed-fee contracts and where they were fixed-price contracts, because most of the latter were so high as to require renegotiation and thereby to become in effect cost-plus-whatever-the-Government-would-allow-as-profits contracts. This was particularly true of aircraft contracts, where the fixed prices bore very little relation to the actual cost after mass production methods were evolved and put into practice. . . .

"The committee made a detailed investigation of the situation at Dallas, Texas, which had been declared by the WMC to be a critical labor area, solely because of the requests of North American Aviation Co. North American has made a major contribution to the war in the design and production of the Mustang and Mitchell planes and in the production of planes at its parent plant at Inglewood, Cal. The committee's investigation was limited to the manpower situation at North American's Dallas plant, a plant which it had undertaken to operate so far from the parent plant only at the urgent request of the War Department.

"A subcommittee of the committee proceeded to Dallas, Tex., and heard approximately 250 witnesses. The testimony established that North American was not efficiently utilizing the 36,000 workers which it then had and that it could not usefully employ the additional 13,000 workers that it was requesting. A transcript of the record of testimony was turned over to Charles E. Wilson, vice-chairman of WPB, who had been selected by the chairman of the WPB to supervise the aircraft industry because of his outstanding achievements as a production expert and as president of General Electric Co. Mr. Wilson consulted with the North American management and with representatives of the Army Air Forces and the WMC in Dallas, and informed the committee that the estimated manpower requirements of the North American plant at Dallas could safely be reduced from the previously announced peak load by approximately 10,000 workers. Mr. Wilson further informed the committee that no new employees would be required by North American until January, 1944, except for replacements, and that after that time new employees would be hired only on a gradual scale based upon new and more realistic schedules. Both Mr. Wilson and Maj. Gen. Charles E. Branshaw, commanding general, Army Air Forces, Materiel Command, Wright Field, deserve credit for the prompt and capable manner in which they handled this situation. . . .

"The investigation at Dallas had a profound effect upon the aircraft companies, particularly those on the West Coast. After re-examining their actual needs, they reported to Charles E. Wilson in the WPB that in their opinion their requests for additional workers could safely be reduced."

AMPHIBIOUS TANK: *In Kwajalein lagoon, this amphibious tank is moving from a Coast Guard-manned transport toward the beach of Namur during the recent invasion of this atoll. These powerful sea-going tanks haul fighting equipment through the surf to the beachheads.*

Egypt Examines Possibilities for a Postwar Hydro-Electric Steel Plant

• • • **An examination** of the possibilities of Egypt becoming at least self-sufficient in regard to its steel needs was made recently by Ernest Menczer, of Cairo. He pointed out that at present there are only a few foundries in the country that depend entirely upon scrap as a metal source, and no facilities are in operation for reducing metal from ore. In spite of the lack of industrial development, there are known iron ore deposits in Upper Egypt near Aswan where at least 980,000,000 tons of 40 to 60 per cent ore exists, 280,000,000 tons of which can be strip mined. In addition, there are also known deposits of manganese, molybdenite, and tungsten ores. The major deficiency and a vital factor is there is no coal available except by importation. One answer to this is electrical reduction of ores, possible by building an hydro-electric plant at Aswan.

It is felt that if at the end of the war the world returns to a system of free competition and free trade without protective tariffs, a steel industry in Egypt would have little or no chance of survival unless the cost of electrical energy and other factors reduce production costs to a level that will permit such products to compete in world markets. However, if such an industry is given governmental support by means of tariffs and other measures it is entirely feasible that the construction of such a plant would make the nation self-sufficient and have enough material left over for future subsidiary industries.

On the other hand, should the postwar world economy become one of a universal economic system to eliminate international competition and to impose restrictions on output in accordance with world demand, it is then considered quite necessary to exploit the Aswan iron deposits and develop Egyptian water power resources without regard to competition.

As to the economics of electrical reduction of ores and electrical smelting of metals, this has been proved on a small scale by electric blast furnaces in Sweden, Norway, Italy, and Switzerland, where very high grade metals have been made. The first world war saw the development of the use of electric blast furnaces and it is believed progress made in the field of metal production should permit perfection of these methods to such an extent that after the war it will be possible to economically construct and operate electrical blast furnaces.

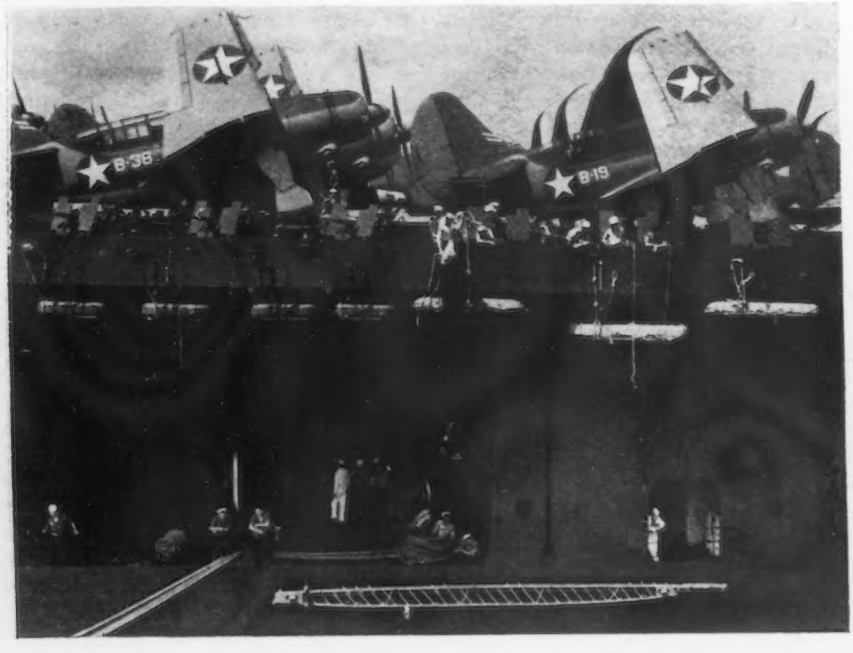
The development of an hydro-electric power system at Aswan would also permit the construction of chemical fertilizer plants, a product that Egypt imports to the extent of 2,000,000 lb. per year.

The need and plausibility of such a project is compared to some extent with the steel industry in India. However, it is acknowledged that Indian ore, running as high as 60 per cent Fe, and fine coal deposits make India a much more natural country for such industrial development. It is pointed out that all these natural resources in India have not contributed to the development of steel manufacture nearly as much as the steel requirements of India.

If the world goes back to a free trade and free competition economy, it is recommended that the Aswan project be undertaken either by the State or by a company with granted tariff protection to insure success. Egyptian needs in finished steel production total about 200,000 tons annually, consisting mainly of structurals, bars, angles, rail, and sheet. This represents about 0.1 per cent of world finished steel production, it is estimated. Even with complete electrification of ore reducing equipment, however, such a project still would be dependent upon coal or coke imports, since about 700 to 900 lb. are necessary per ton of pig iron produced.

On the development of such a project also hinges the establishment in Egypt of several allied industries, at present non-existent in the country. These would include manufacturers of machinery, boilers, tools, railroad cars, electrical apparatus, hardware products, etc. At present Egypt not only lacks a machine industry, but does not even posses a factory for the production of quite primitive agricultural implements such as ploughs.

HELLDIVERS: *These Curtiss-Wright Helldivers are stowed on board going into a theater of action. They form a "canopy" over the liferafts that can be seen secured to the side of a Navy aircraft carrier. Gun stations may be observed just over the life rafts.*

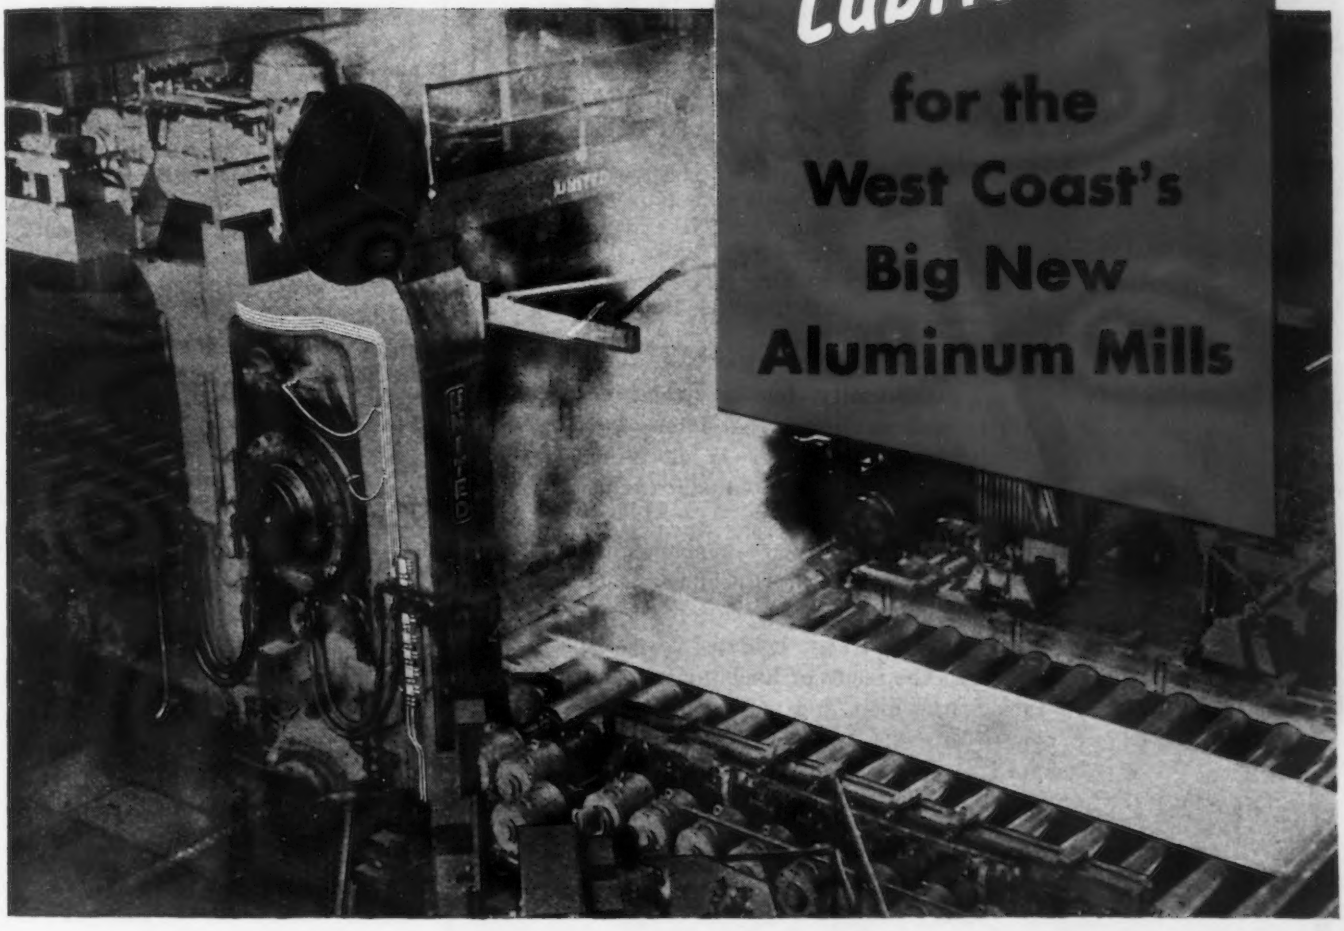


Almost Eight Billion Spent In February for War Purposes

• • • **United States** expenditures for war purposes hit a new high in February, $7,808,000,000 as compared with $7,416,000,000 in January, an increase of 5.3 per cent. The previous high was in November, 1943. The average daily rate for war expenditures in February amounted to $312,300,000.

From July 1, 1940, through February 29, 1944, the government expended $168,600,000,000 for war purposes. War expenditures for the fiscal year 1944 now amount to $58,600,000,000, as compared with $45,600,000,000 expended through February during fiscal year 1943.

Positive Lubrication for the West Coast's Big New Aluminum Mills



FARVAL SYSTEMS serve over 2300 Bearings

From farmland to integrated plant in record time, these new Aluminum Mills at Trentwood are already producing on schedule. To help maintain top output, Farval Centralized Systems are delivering lubricant on schedule and at regular intervals to *every one* of the more than 2300 bearings on Hot and Cold Mills, Skin Pass Mills, Shears, Trimmers and other equipment. Farval will help maintain top production in *your* plant too. Get Farval facts now.

Pilot Foundry Heads Post War Planning

Mahwah, N. J.

• • • **The American Brake** Shoe Co. opened its new Experimental Foundry at Mahwah, N. J. This pilot plant, instead of operating on a miniature basis, is a full-sized foundry capable of handling castings up to 2000 lb. gross weight. But only experimental work will be done in the foundry.

This plant had been planned as a further step in the company's extensive program of metallurgical research, but the priority situation on construction materials had postponed erection. Then it was learned that the U. S. Army Air Forces, Wright Field, were concerned with the procurement of forgings for aircraft needs and were considering the possibility of substituting centrifugal and static castings to ease the situation.

Since such castings required considerable piloting before they could be ready for production, Wright Field engineers approached Brake Shoe in the matter and arranged for the Army Air Forces to sponsor a priority application for the foundry. The construction was promptly authorized by the WPB and a Correlation Research Project was assigned the company by the War Metallurgy Committee of the National Research Council.

To save time and conserve new steel for direct war purposes, it was decided to buy an idle plant at Kansas City, Kansas, which was dismantled and 250 tons of structural steel and sash were shipped to New Jersey.

Everything in the way of modern foundry equipment and standard safety devices have been included.

This experimental foundry will be directly and indirectly in the service of the government for the remainder of the war. Its immediate work will be devoted to: 1—Development of pilot centrifugal and static castings practices for the aircraft industry. 2—Experimental work assigned by the War Metallurgy Committee. 3—Research projects that have a bearing on the war for the eight operating divisions of the company.

After the war the principal activity of the foundry will be experimental and research work for the company. Much of it will consist of investigation of new processes or products of interest to any of the company's hot metal divisions. A great deal of it will be to seek improvement of present

There are many GOOD THINGS AHEAD . . .

One proposed use for obsolete war planes is for the quick freezing of foods. Cargoes of freshly picked fruits and vegetables may be flown directly from the fields to high altitudes. There the compartments will be opened and the contents immediately frozen by the intense cold.

More than 2,000 varieties of plants have been tested for rubber during the last year.

A resin bonded panel of plywood, with a sprayed coating of steel, has eight times the strength of either material alone.

Electronic hearing devices are now so sensitive that the growing noises of a blade of grass may be heard.

One use suggested for the Helicopter is to carry girders and beams to high buildings or bridges and hold them in place while they are being fastened. This would make derricks, elevators and cranes unnecessary for this purpose.

Magnets are being used by draftsmen to hold drawings in place on steel-cored drafting boards.

Three stages of post-war development in railway locomotives are predicted. First, the high-efficiency turbine, using super-heated steam at 600 to 700 degrees. Second, the oil-burning internal combustion turbine. Third, the same type of turbine with a gas-producer using coal.

A small hand tool now "spot-welds" thermoplastic resins electronically.

So rapid are changes in technology that, for purposes of government bookkeeping, synthetic rubber plants are assumed to become obsolete in five years.

Transparent plastic, reinforced with glass fibers, is being used in aircraft construction. The material is said to have ten times the impact strength of ordinary plastics.

For twenty years people have been laughing scornfully at the "seadromes", 65,000 ton, 10 million dollar islands for transatlantic passenger planes. Now that seemingly fantastic project is being seriously considered by several large steel, shipbuilding and air transportation companies. Supported on floats 160 feet below water and extending 70 feet above the surface, the seadromes are unaffected by waves and would furnish a safe, level landing and refueling place as well as luxurious hotel accommodations.

Steel alloys, whose exact compositions are unknown, can now be quickly identified by the use of a small radio-like apparatus.

The most powerful electric motor in the world has recently been completed. It develops 7,000 horsepower at a speed of 25 r.p.m.

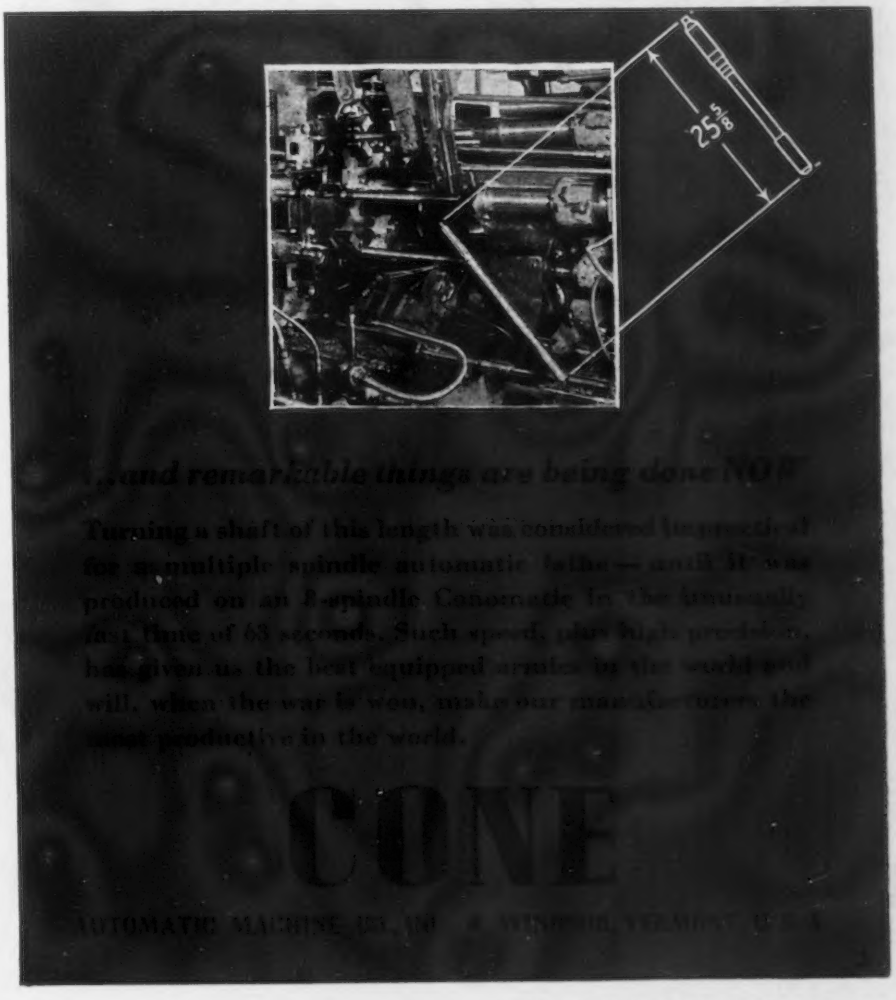
Seventy-two refineries are now making 100 octane gasoline, the production of which has increased 400% in the last year, and is expected to double again in the year ahead.

By the use of a new ultra-high frequency, resonator telephone engineers expect to send six-hundred thousand conversations or television pictures at one time through a six inch pipe.

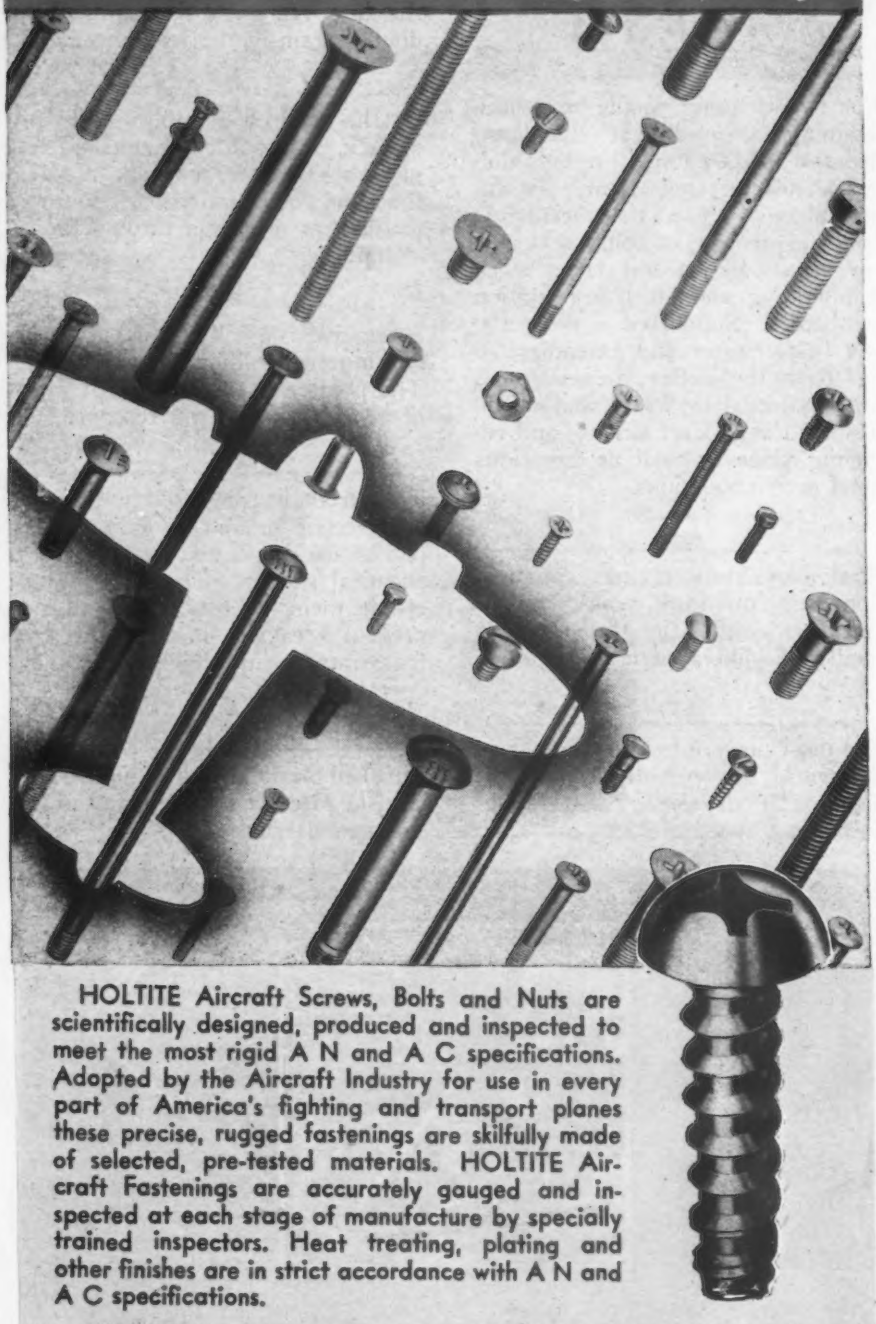
A new balance will weigh as little as two-hundred millionths of an ounce. The pointer is so tiny that it must be read through a microscope.

The carbon brushes used in the various electric motors of fighting airplanes are small, but vital. A new chemical process is reported to increase their life fifty times, and to prevent breaking down at the low temperatures in which they must operate at high altitudes.

Punched plastic sheets are now being used in place of cedar separators in storage batteries.



Precision AIRCRAFT fastenings



HOLTITE Aircraft Screws, Bolts and Nuts are scientifically designed, produced and inspected to meet the most rigid A N and A C specifications. Adopted by the Aircraft Industry for use in every part of America's fighting and transport planes these precise, rugged fastenings are skilfully made of selected, pre-tested materials. HOLTITE Aircraft Fastenings are accurately gauged and inspected at each stage of manufacture by specially trained inspectors. Heat treating, plating and other finishes are in strict accordance with A N and A C specifications.

HOLTITE "Thread-Forming" SHEET METAL SCREWS

When Speed Nuts are used with HOLTITE Sheet Metal Screws, the small, tapered point permits a quicker start and run-on of nut. The smooth threads with faster lead reduce nut-turning time and provide a much tighter lock to resist vibration.

Cutting their own threads—in metal or plastics as they are driven in, these production-boosting screws eliminate time-consuming tapping operations and effect a stronger, tighter fastening as each thread stays tight in the perfect mating thread it has cut in the material. Available with slotted head or HOLTITE Recessed Head.

CONTINENTAL SCREW CO. New Bedford, Mass., U.S.A.

BUY MORE WAR BONDS

products by changes in foundry practices, melting techniques, and rigging.

Personnel training will be a major role of the experimental foundry. It is planned to put apprentices through a short training period in the foundry and then release them as they may be needed to the operating divisions.

When it again becomes possible to employ professional engineers, a group of field metallurgists will be established to work in conjunction with the Experimental Foundry. These men will assist in developing new markets and new products for present markets, through a correlation of laboratory efforts with industrial needs. At all times the foundry is intended to be a changing, modern exhibit of good foundry practices.

Postwar Trade With China Studied by Council

• • • **Stressing** the mutual benefits to the United States and China of expanded postwar trade, Richard C. Patterson, Jr., president of the China-America Council of Commerce and Industry, recently announced in New York the development of a program based upon full cooperation and understanding.

Mr. Patterson, former assistant secretary of commerce, visualizes great possibilities for two-way and cooperative trade with China and points out that production to meet pent-up civilian needs throughout the world would greatly ease the employment problem in this country after the war.

The program, as outlined by Mr. Patterson, includes analyses of treaties, trade policies and the proposed International Monetary agreements; comparative studies of American and Chinese business laws and their effect on China-American trade; studies of commodity loans; development of Chinese natural resources and industries; postwar air and other shipping routes and the training of Chinese technicians in America. A detailed examination of China's Reconstruction Plan is also contemplated. He continued:

"With China now easing restrictions on foreign investments and evidencing a desire to build the strongest possible trade ties with the United States, the China-America Council is endeavoring to provide a solid basis for business and industry to work hand in hand with all concerned in the development of this world market.

PRECISION BOMBING

Precision must be the watchword of both the falling bombs and the sweetly purring engines to assure a successful mission. Just as the Norden bomb sight provides pin-point aiming when the bay doors swing open above a target, so Perfex gages impart that final touch of precision accuracy to the giant power plants. This kind of teamwork spells top flight performance all around. While serving war production needs, Perfex devoutly hopes soon to be filling postwar requirements.

★ Perfex manufactures thread plugs, thread rings, plain plugs, plain rings and special thread gages to blueprint. For complete information and prices wire or write our sales department today.

Foundry Equipment and Furnace Orders Are Charted

• • • **The trend of orders for foundry equipment, which rose to $3,500,000 last October as a result, mainly, of the accelerated truck program, has continued at this higher level. Shipments have been running level with orders received so that the backlog, which is slightly in excess of two months' current production, has remained level or risen slightly during the last quarter of 1943, according to WPB.**

The level of unfilled orders for metal melting furnaces remained fairly stable throughout 1943. Due to the importance of foreign requirements in this field the trend of new orders fluctuates sharply. As of the end of December, 1943, the backlog of unfilled orders represented approximately ten months' production.

Foundry equipment includes annealing ovens (malleable castings); blast cleaning equipment, sand or metal abrasive; briquetting equipment for iron and steel borings and turnings; core-making and core-crushing machines; cupolas; dust collecting equipment; ladles, for transporting and pouring iron, steel, and nonferrous metals; molding machines; conveyors; mold, and molding sand; ovens, core and mold sand reclaiming equipment; sand handling and sand preparation equipment; shakeout equipment; steel shot and grit for blasting; tumblast and rotoblast equipment; tumbling barrels and mills for cleaning castings. These data are based on the reports of approximately 90 companies and represent approximately 95 per cent of the industry. Repairs and replacements were approximately 15 per cent of shipments in the case of electric metal melting furnaces and slightly over 24.5 per cent in the case of foundry equipment on the basis of reports for the year 1943.

Alvey-Ferguson Conveyors Will Help This Stoker Plant Produce 20 Postwar Stokers Per Hour!

YOU KNOW that you must make your postwar products more economically.

You know that efficient conveyorized mass production lowers production costs.

Isn't it wise, then, to write us for a discussion of your indoor transportation problems *before* final plans are made to re-convert *your* plant to postwar production?

Perhaps we can help *you*—as we helped *this* well-known manufacturer of stokers.

The A-F Conveyor System shown above was designed to handle 20 units per hour. Sub-assembly work is handled on the roller conveyors. The A-F Trolley Conveyor acts not only as a carrying medium through dipping, painting and spraying operations, but conveys parts from storage, through machining, fabricating and finishing to storage and assembly. In addition, it acts as a stock bank releasing floor space for other purposes and eliminates wide trucking aisles.

Everything possible has been done in this plant—and will be done in yours—to make for more efficiency and lower costs. Write today.

Reports of Firms' Ordnance Feats Are Sought for History

• • • **Permanent** recognition for the war role being played by individual Ordnance producing firms can be obtained if the companies will prepare a report of their achievements.

The Historical Section of the Ordnance Department is anxious to receive narrative accounts from the individual companies, to be used in connection with the writing of a complete history of industry-Ordnance efforts in this war. It is expected that the history will be published in permanent form, in a number of volumes. Thus, valuable information for future industrial preparedness will be preserved.

Ordnance producers are requested to submit to 705 Mills Building, Washington 6, a narrative account of production activities for the Ordnance Department in World War II, dating from the commencement of such activities and covering the period from that date to Dec. 31, 1943. Thereafter, supplementary accounts covering 90-day periods, the first of these for the months of January, February, and March, 1944, are desirable within 30 days after the close of each such period until the completion of the company's final U. S. Ordnance contract for the present war.

Primary factors which might well receive treatment in each of the accounts prepared include: Speed of conversion; quality and quantity of production; overcoming production obstacles; unusual contributions to development and improvement of ordnance material; avoidance of work stoppages; maintenance of fair labor standards; records on accidents, health, and sanitation; relations with the Ordnance District Office. To these, a final topic might well be added, namely, research and development.

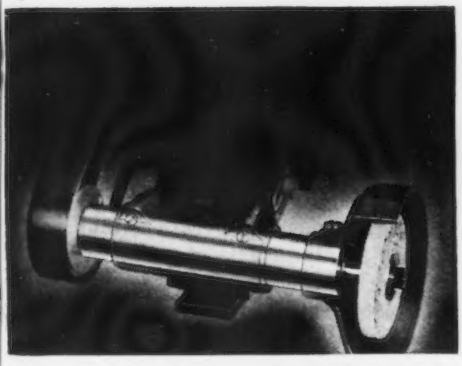
Pratt & Whitney Issues Book Depicting 1943 Events

• • • **Events of** 1943 at Pratt & Whitney, West Hartford, Conn., have been recorded by the company for its employees in a 32-page "year book" which is profusely illustrated.

After a foreword by C. W. Deeds, president and general manager, and C. R. Burt, chairman, the book depicts manufacturing activities and then covers employee activities at length. Two pages are devoted to a list of employees in the armed forces.

NOT A TIME BOMB

BUT A PACKAGE OF PRECISION



WHICH WILL EXPLODE MANY OLD NOTIONS OF PRODUCTION COSTS

Do you think high tooling costs must inevitably accompany volume production of precision parts? *This is not always true today* — as experience has proven in the numerous war plants which have discovered the "Production-with-Precision" potentialities of this sleek, shining steel cylinder. It is the quill (essential heart) of the Dumore Precision Grinder, the tool which converts existing machine tool equipment of various sorts to production grinders of high precision . . . at remarkably low cost.

As war requirements change, or conversion to peace goods takes place, the adaptability of this high-precision tool to a wide range of applications will be a major factor in keeping overhead down —quality and volume *up*.

You will find the full story of the "Dumore System" interesting, helpful and stimulating. Get the facts, today. Ask your industrial distributor, or write direct to The Dumore Company, Department TC24, Tool Division, Racine, Wisconsin.

A PRECISION TOOL FOR PRECISION RESULTS

Typical of the Dumore manufacturing methods which "build-in" the engineered precision is the assembly of the quill in a special department, air-conditioned to maintain constant temperature and exclude dust. The vibrationless, high-speed operation (up to 42,500 r.p.m.) and the stamina to maintain precision through long periods of continuous operation, are achieved only by scientific design and painstaking workmanship. Details in complete Dumore catalog, full of helpful data on grinding. Yours for the asking. Send for it, NOW!

Michigan Manpower Replacement Plan Mapped

Lansing, Mich.

• • • **Michigan Selective** Service headquarters announced recently a plan for calling war workers into the draft which, in effect, turns them over to the services as soon as cutbacks or contract completions cause their layoff.

The state's employers were "advised" to make immediate revision in their replacement schedules when contract cutbacks or cancellations reduce payrolls. The indication was that when no replacement schedules exist, the plant will be expected to release draft-eligible men first, regardless of any union seniority agreements that may exist.

It was pointed out that where replacement schedules are filed, there is no conflict with union seniority rules. A plant could reduce its working force by several hundred men, for example, in accordance with its union seniority list, and then notify selective service of its need for that many fewer men. Draft calls would be made in deferment sequence, and as these reduced the number of men at work in the plant, the workers laid off under union seniority would be called back. In practical effect, of course, this would amount to handing the draft the most eligible men first, rather than make the plants targets of accusations that they held onto younger men and released workers above 38 during layoffs. An accusation of this sort was recently made by New York selective service officials.

100,000 Worker Recruit Plan Mapped for Railroad

Washington

• • • **A campaign to fill** 100,000 present and impending job vacancies on the railroads of the nation was announced by ODT. The manpower drive will be conducted by a newly established Railroad Manpower Mobilization Committee representing the united efforts of the government and railroad labor and management. It is composed of representatives of the WMC, ODT, Railroad Retirement Board, Association of American Railroads, the railroad labor organizations, and OWI.

Additional employes, both men and women, are needed in virtually all categories of railroad work. While no serious tie-ups have yet occurred in the transportation there has been

some local congestion caused by lack of manpower, and unless offset by remedial action, such congestion is bound to become serious.

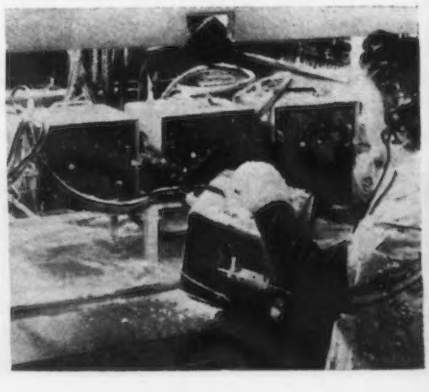
From the information assembled by the ODT, the major needs of the railroads throughout the country are for ten classifications of labor. These are: Shop workers, such as machinists and blacksmiths; track men; bridge and building mechanics; workers for freight houses, stores and roundhouses; brakemen for both yard and road services; locomotive firemen; clerks of all kinds; telegraphers, telephoners, and towermen; signal men and signal maintainers; and marine workers, licensed and unlicensed.

New Handbook Covering Mechanical Springs Out

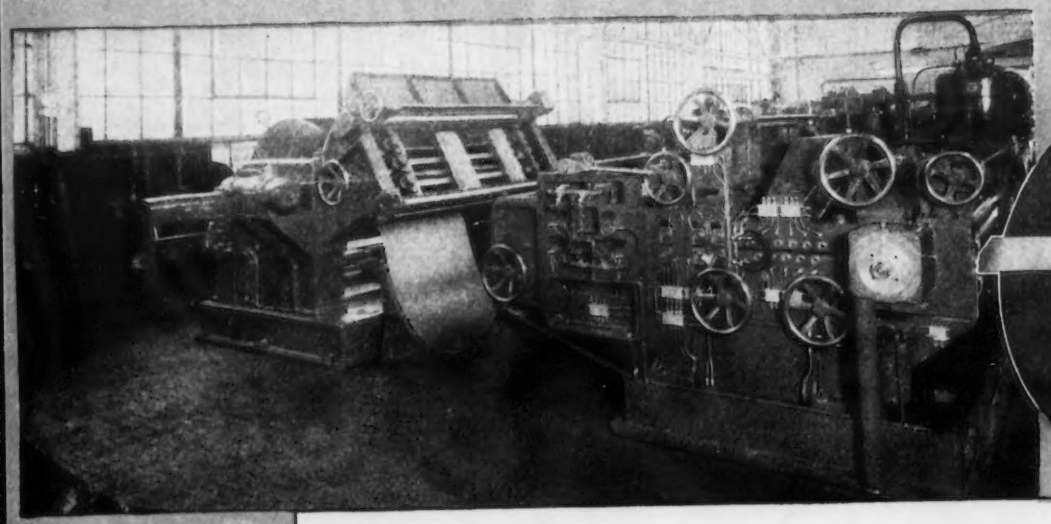
• • • **A new handbook,** "Mechanical Springs, Their Engineering and Design" has been issued jointly by the divisions of the Associated Spring Corp. It consists of around 110 pages and is profusely illustrated. Contents include charts and formulas upon which the design of all types of mechanical springs is based.

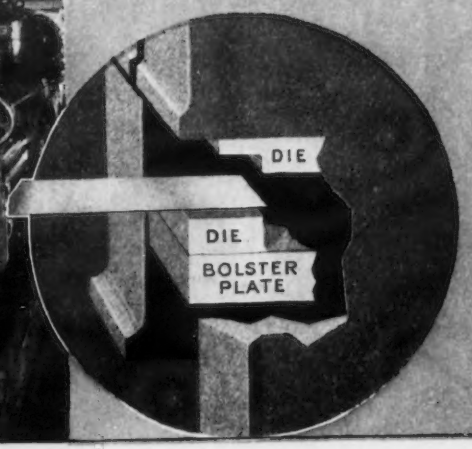
Copies may be obtained by qualified engineers and purchasing agents by writing the nearest of the divisions of the Corporation: Wallace Barnes Co., Bristol, Conn.; Barnes - Gibson - Raymond, 6400 Miller Ave., Detroit 11, and Cook plant, Ann Arbor, Mich.; F. N. Manross & Sons, Bristol, Conn.; William D. Gibson Co., 1800 Clybourn Ave., Chicago 14; Raymond Mfg. Co., Corry, Pa.; Dunbar Bros. Co., Bristol, Conn. In Canada the division is Wallace Barnes Co., Ltd., Hamilton, Ont.

SUB-ZERO TEST: *These radio instruments are being removed from a sub-zero testing chamber at the Radio Division of Bendix Aviation Corp. Such tests are incorporated in the routine inspection procedure for these aircraft radios to insure that they will function perfectly at the —65 deg. F. temperatures in which high altitude bombers operate.*



McKAY Announces a New





CONTINUOUS PROCESSING and PRESS FEEDING LINE FROM COILED STOCK for POST-WAR PRODUCTION

1. This Line Flattens the Strip
2. Feeds and Measures Stock to the Dies
3. Eliminates Stretcher Strain
4. Minimizes Die Drawing Difficulties

The schematic drawing illustrated below shows the flow of strip from coil to press

Materials Handling And Presses Described In Enemy Patents

• • • **This is the nineteenth** list of seized enemy patents, available on license from the Alien Property Custodian. These patents are grouped in classes. Sub-class numbers are shown first in parentheses, followed by the patent number, description of the patent, the inventor's name and nationality, and the date of issuance.

This series began in the Nov. 4 issue of THE IRON AGE, page 95, at which time procedures for obtaining the patents for use were described with information concerning their usage and possibilities. Seized patent applications were shown in THE IRON AGE on July 8.

Class 214—Material or Article Handling

(1) 2,117,523. Automatic barrel-treating machine of the type in which barrels move through several stations where they are successively treated. W. Strohl, Germany. 5-17-38.

(1) 2,198,976. Apparatus for conveying cigars and fillers. C. Rober, Germany. 4-30-40.

(1.10) 2,222,745. Apparatus for emptying chocolate molds or the like wherein the molds are subjected to a cooling operation. M. Heidelmeyer, Germany. 11-26-40.

(2) 1,794,299. Material receptacle for automatic weighing machines. W. Kader, Germany. 2-24-31.

(8.50) 1,862,386. Apparatus for removing articles from a pile. J. Neff, Germany. 6-7-32.

(11) 1,810,442. Sheet cutting machine comprising a driving shaft and means for conducting the sheets to separate piles according to their quality. G. Spiess, Germany. 6-16-31.

(11) 1,957,260. Machine for separating maculate parts of sheet paper. A. Gayler, Germany. 5-1-34.

(12) 1,823,172. Method of and apparatus for unloading boats, barges, and like vessels. K. Schon, Germany. 9-15-31.

(15) 1,750,095. Hold for dredgers. F. Ewig, Germany. 3-11-30.

(16.10) 2,024,190. Automobile parking and storage machine. R. Sumi and N. Sasayama, Japan. 12-17-35.

(17) 1,692,610. Silo of the kind adapted for use with powdery and granulated materials. E. Barthelmess, Germany. 11-20-28.

(17) 1,866,124. Conveying apparatus, particularly for electroplating. J. Oertli, Germany. 7-5-32.

(17) 1,921,206. Apparatus for passing articles suspended from supporting devices through baths. J. Oertli, Germany. 8-8-33.

(17) 1,935,506. Loading centrifugal extractor. H. Krantz and H. Buysch, Germany. 11-14-33.

(18) 1,668,825. Discharge funnel for silos. E. Sobek, Austria. 5-8-28.

(18) 1,824,483. Apparatus for operating shaft furnaces in the thermal treatment of granular material. O. Hubmann, and F. Voerkel, Germany. 9-22-31.

(18) 1,835,225. Charging device for shaft furnaces. E. Knoringer and C. Wolski, Germany. 12-8-31.

(18) 1,943,634. Coke oven charging machine. C. Still, Germany. 1-16-34.

(18) 1,943,635. Coal charging truck. C. Still, Germany. 1-16-34.

(18) 2,015,451. Apparatus for charging furnaces. E. Gerlach, Germany. 9-24-35.

(18) 2,032,564. Device for charging gas generators and the like. T. de Fontaine, Germany. 3-3-36.

(18) 2,121,133. Furnace charging device. C. Still, Germany. 6-21-38.

(23) 1,674,007. Coke-pushing machine. E. Grasshoff, Germany. 6-19-28.

(23) 1,763,918. Apparatus for moving ingots or masses in furnaces. W. Bangert and M. Peters, Germany. 6-17-30.

(23) 1,979,419. Leveling bar for a coke oven. C. Still, Germany. 11-6-34.

(35) 1,607,623. Furnace-charging mechanism. H. Schaffert, Germany. 11-23-26.

(35) 1,670,203. Automatic charging hopper for receptacles especially for producers. R. Moller, Germany. 5-15-28.

(35) 2,148,465. Fuel-charging apparatus. J. Hein, Germany. 2-28-39.

(35) 2,151,514. Method of and apparatus for

FOOTWORK— ON THE OCEAN

Another Success Story for BARIUM STEEL

"FULL SPEED AHEAD . . . FULL SPEED ASTERN" . . . Now to port, now to starboard — a PC Boat must be able to *maneuver* faster than the submarine it's chasing.

This rapid "footwork" puts a test on the propeller shafts — a test in strength and toughness that is met by BARIUM STEELS

Melted and refined in Barium's Furnaces.

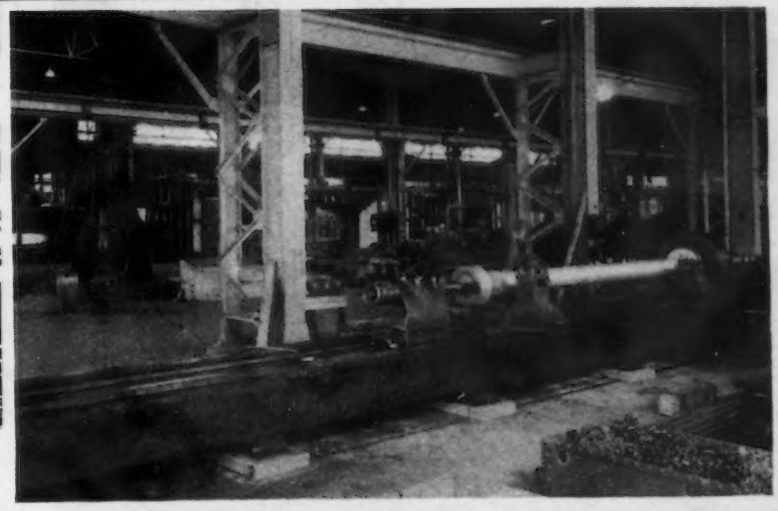
Forged under Barium's Hammers and Giant Presses.

Scientifically Heat Treated.

Turned on Barium's Lathes.

Propeller shafts in PC Boats are proving the value of *unified control* — from the first melt to the final turn — a reason for the growing success of Barium Steels in propeller shafts and thrust bearings for naval vessels . . . breech blocks and housings for naval ordnance.

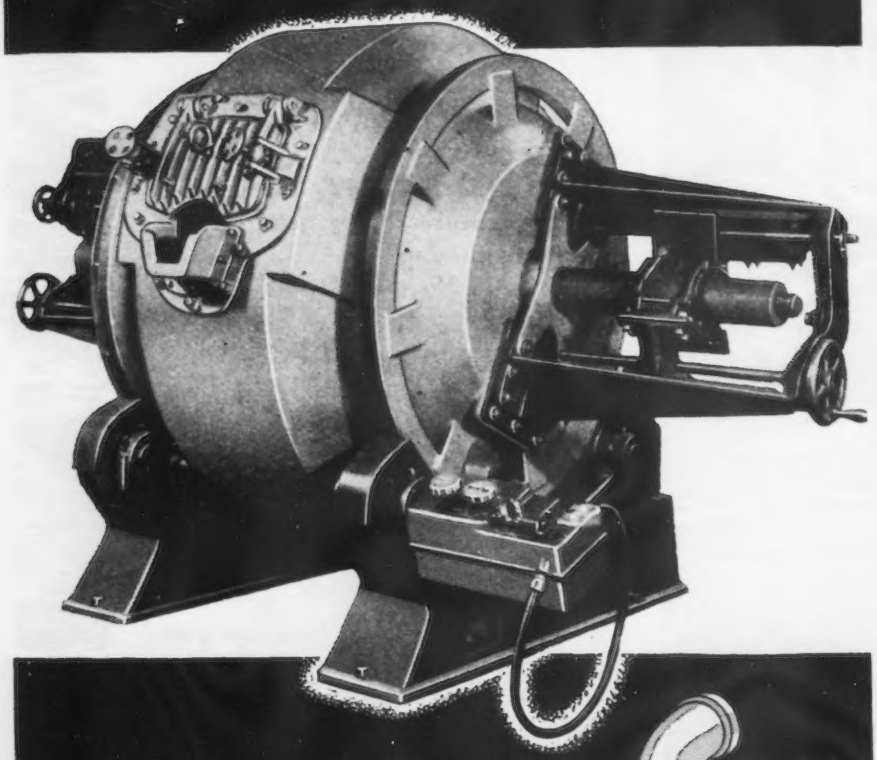
We invite your inquiries for Die Blocks, Hammer Rods and Heavy Forgings.



BARIUM STAINLESS STEEL CORP.

Producers of Stainless, Alloy, and Carbon Steels **CANTON, OHIO**

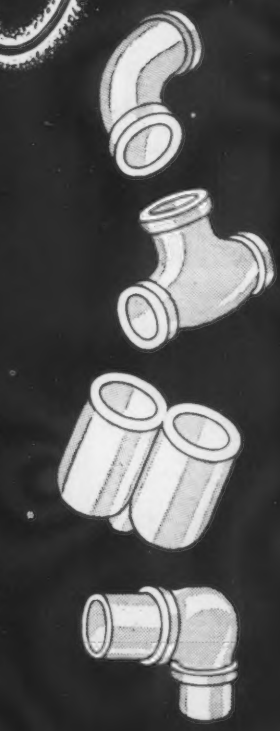
Better Metallurgical Results with Detroit Rocking Electric Furnaces



There are two main reasons why Detroit Rocking Electric Furnaces give you better Metallurgical results. They provide an automatic stirring action under non-oxidizing conditions and they allow precise control of time, temperature and composition.

Because of their high melting speed you can produce as many as eight ferrous heats or sixteen non-ferrous heats in one eight-hour shift. And you pour these heats with a minimum of dirt, fumes and hard work.

Built in sizes from 10 to 8000 lbs. molten metal capacity there is a Detroit Furnace to fit your needs. Write today for facts and prices.



DETROIT ELECTRIC FURNACE DIVISION
KUHLMAN ELECTRIC COMPANY • BAY CITY, MICHIGAN

conveying material containing at least one expansible constituent. W. Heinen, Germany. 3-21-39.

(38) 1,741,374. Loading-plant especially designed for building-stones of any kind, such as lime stones or sand stones, bricks, clinkers and the like. W. Mortz, Germany. 12-31-29.

(65) 1,944,063. Loading device especially for trucks. F. Brauner, Austria. 1-16-34.

(67) 1,739,183. Truck for removing house refuse. P. Schuberth, Germany. 12-10-29.

(67) 1,753,135. Door for vehicles for removing house refuse. P. Schuberth, Germany. 4-1-30.

(67) 1,776,034. Dust cart adapted to prevent the escape of dust or refuse during the emptying of the dust bins or containers into it. H. Krahn, Germany. 9-16-30.

(67) 1,781,346. Dust cart for the conveyance of granular material. K. Schmidt, Germany. 11-11-30.

(67) 1,831,648. Process for the complete filling and emptying of receptacles such as dust-carts. J. Bauer and A. Umbach, Germany. 11-10-31.

(67) 1,863,964. Rubbish cart built in the form of a motor driven vehicle comprising a rubbish container with a rubbish propeller arranged in its interior. G. Brenner, Germany. 6-21-32.

(67) 1,963,288. Device for emptying refuse receptacles into refuse-collecting vehicle. O. Ballert, Germany. 6-19-34.

(67) 2,113,685. Refuse vehicle. M. Leopoldo, Italy. 4-12-38.

(67) 1,996,945. Self-loading vehicle. O. Ballert, Germany. 4-9-35.

(67) 2,252,608. Dust cart in which the refuse is dumped at the rear of the cart through a hopper and is pressed into the interior of the cart by means of a rudder-like wall member. O. Ballert, Germany. 8-12-41.

(89) 1,676,041. Unloading machine. S. Nagao, Japan. 7-3-28.

(95) 1,978,153. Cooling bank plant with several delivery channels. F. Zabel, Germany. 10-23-34.

(95) 2,187,100. Automatic control for switching cars on and off mine cages. K. Ruhl, Germany. 1-16-40.

(115) 1,722,125. Lifting machine such as a crane. J. Bernhard, Germany. 7-23-29.

(119) 1,851,074. Concrete conveying bucket. T. Wagener, Germany. 3-29-32.

(135) 1,940,616. Convertible implement for excavating. K. Wissmann, Germany. 12-19-33.

(138) 2,000,150. Instroke excavator. H. Siebert, Germany. 5-7-35.

(138) 2,191,569. Drag shovel. J. Kuhsel, Germany. 2-27-40.

(140) 2,055,111. Drag shovel excavator. H. Siebert, Germany. 9-22-36.

(146) 1,988,862. Control for excavators. K. Wissmann, Germany. 1-22-35.

(152) 1,686,167. Vehicle for receiving and transporting refuse and the like. H. Neuy, Germany. 10-2-28.

(1) 1,994,399. Device for the transportation of goods both on railways and on the road. G. Moreau, France. 3-12-35.

(3) 1,914,711. Load lifting and discharging apparatus. C. Carmillet, France. 6-20-33.

(5.5) 2,058,815. Apparatus for threading tobacco leaves upon a string for the purpose of drying said leaves. P. Muller, France. 10-27-36.

(8.5) 2,253,050. Apparatus for feeding compression molds for cigar fillers. C. Rober, Germany. 8-19-41.

(11) 1,760,058. Tar-separating apparatus. H. Hennebutte and E. Goutal, France. 5-27-30.

(11) 1,774,447. Sorting or distributing apparatus. J. Marchand and J. Andriessen, Netherlands. 8-26-30.

(11) 1,852,428. Container for distributing or sorting apparatus. J. Marchand and J. Andriessen, Netherlands. 4-5-32.

(11) 1,856,165. Apparatus for sorting and distributing mail matter. J. Marchand and J. Andriessen, Netherlands. 5-3-32.

(15) 1,868,035. Device for trimming coal and like material in ships. D. Valstar, Netherlands. 7-19-32.

(16.1) 2,028,476. Garage for automobiles and the like. J. Rome and K. Rubinstein, France. 1-21-36.

(16.1) 2,297,199. Device for receiving, conveying, or transporting bulky objects. H. Buddecke, Germany. 9-29-42.

(18) 1,668,968. Charging device for gas producers, shaft furnaces, and the like. J. Lambot, Belgium. 5-8-28.

(18) 1,788,289. Means for supplying fuel to furnaces. J. Gogelein and C. Schoonenberg, Java. 1-6-31.

(18) 1,887,292. Device for distributing the charge in an oven. A. de Saint Hubert, Belgium. 11-8-32.

(36) 2,141,506. Apparatus for charging furnaces. A. Bongarcon, France. 12-27-38.

Widely variable speed ranges upon request.

These versatile machines can also be equipped for thread cutting, drum scoring, or angle turning.

Ask Bullard Engineers about the Four Speed Ranges obtainable.

Send for Circular, giving full specifications.

THE BULLARD COMPANY

BRIDGEPORT 2, CONNECTICUT

"SPECIAL" SERVICE

When you need "specials" call in our nearest Field Engineer who is fully qualified to help you. Or... send us drawing, sketch, or blue print with all angles and sizes shown. Specify grade of KENNAMETAL or describe work to be done. If chip breaker is needed, indicate on drawing, or give feed and depth of cut. For complete instructions see our new Tool Manual. If you don't have it, write for your copy today.

When you require form tools and other special shapes for steel-cutting, come to KENNAMETAL . . . relieve your toolmakers of a laborious, costly, time-consuming job . . . and at the same time be sure of highest degree of tool performance.

KENNAMETAL special tool service provides the facilities, experience, and skilled personnel that few, if any, machine shops have need for or can afford to maintain. By using this service you obtain the help of a staff of trained tool engineers, whose advice assures you of getting the right grade of KENNAMETAL, properly ground to accurate rake and cutting edge angles.

Next time you need "specials," give the job to KENNAMETAL specialists. Depending on requirements, we will economically and promptly supply either complete tools, or formed tips for brazing to shanks in your own shop. Our Catalog 43-C contains a wealth of information on KENNAMETAL tools for all steel-cutting purposes. Write for your copy.

loading wagons. P. Guilbert and J. Legrand, France. 9-27-32.

(38) **2,085,329.** Device for the loading and unloading of wheeled loads on railway cars. A. Porte, France. 6-29-37.

(41) **1,863,984.** Working and loading platform for gallery work in tunnels. C. Hoelfeldt-Lund, Norway. 6-21-32.

(41) **1,905,434.** Hopper crane of the movable and traveling type. F. Boyer, France. 4-25-33.

(44) **1,716,240.** Apparatus for the unloading of railroad cars and other vehicles. C. Postweiler, France. 6-4-29.

(47) **1,801,180.** Wagon-tipping apparatus. H. Tacvorian, France. 4-14-31.

(52) **1,763,545.** Discharging means for open railway wagons. G. Willimek and W. Kozietulski, Poland. 6-10-30.

(67) **2,050,806.** Loader for refuse vehicles. F. Rey, France. 8-11-36.

(67) **2,084,656.** Self-loading refuse vehicle. P. Rottee, France. 6-22-37.

(67) **2,091,519.** Refuse vehicle and the like. L. Noyer, France. 8-31-37.

(67) **2,130,951.** Loading apparatus for vehicles. C. Edwards, England, assignor to F. Rey, Seine et Oise, France.

(84) **1,868,568.** Movable platform for conveying goods chiefly in ship's holds. J. de Andia Yrarrazaval, France. 7-26-32.

(85) **2,305,762.** Apparatus for self-loading vehicles. U. Cristofoletti, L. Laboccetta and E. Persi, Italy. 12-22-42.

Class 100—Presses

(1) **1,669,657.** Machine for roping straw or other vegetable. R. Dunkel and A. Wilde, Germany. 5-15-28.

(41) **1,866,487.** Device for squeezing segmental fruit slices wherein the curved edge of one pressure plate is bent up to form a flange or rim which runs concentrically to the curved edge of the other pressure plate. F. Ritter, Jr., Germany. 7-5-32.

(41) **2,037,553.** Portable lemon slice squeezer for table use. S. Wagner, Germany. 4-14-36.

(44) **1,819,704.** Power press in which the advantages of mechanical and fluid operation are combined. A. Friz, Germany. 8-18-31.

(48) **1,769,658.** Press for the treatment of moist materials, for instance oil containing materials of the kind in which the material is continuously passed through a pressing chamber narrowed towards the discharge end, and the oil or other fluid expressed escapes through the walls of the pressing chamber. G. Veenhuyzen, Netherlands. 7-1-30.

(48) **1,840,263.** Press for moist material especially suitable for pressing oil-producing fruits and seeds. K. Sohler, Germany. 1-5-32.

(48) **2,165,134.** Process of preparing enamels, for instance on cast iron or wrought iron, having a high resistance to variation of temperature. K. Frank and F. Osterloh, Germany. 7-4-39.

(50) **1,637,671.** Oil press combined with a disintegrating means which has the form of a grid being inserted at the bottom in the mouth of the press space. H. Zander, Germany. 8-2-27.

(50) **1,660,160.** Means for removing compressed matter from containers. P. Hanel, Germany. 2-21-28.

(50) **1,661,614.** Apparatus for pressing out liquid matter from materials of any kind in double cage presses and is designed especially for the pressing of oleaginous materials. P. Kutschbach, Germany. 3-6-28.

(50) **1,672,659.** Straining press for extracting liquids from moist substances of various kinds and of the type having a press chamber of annular cross-section through which the material is passed. K. Sohler, Germany. 6-5-28.

(50) **1,736,262.** Hydraulic pot press for removing the oil from cocoa powder, etc. P. Hanel, Germany. 11-10-29.

(50) **2,213,815.** Horizontal press for the treatment of cellulose sheets with alkaline lye, in which in one and the same container the said sheets are soaked with the lye, the excess of lye is thereupon pressed out, and the treated sheets are discharged from the container for further treatment. F. Jaeger, Germany. 9-3-40.

(50) **2,229,900.** Combined filter and hydraulic press. H. Reitz, Germany. 1-28-41.

(50) **2,253,437.** Hydraulic pot press which serves for pressing cocoa butter from the liquid cocoa mass. K. Leimer, Germany. 8-19-41.

(54) **1,930,903.** Pressing box filter protection, especially pressing boxes of hydraulic cocoa press, in which the cocoa butter is pressed out of the cocoa mass by the application of high presses. M. Michel, Germany. 10-17-33.

(50) **2,306,477.** Filter apparatus combining an ordinary filter chamber with a hydraulic

DETROIT 8, MICHIGAN

Now for the first time..

You can... IN ONE OPERATION do these THREE jobs!

1 Effectively, quickly, safely remove oil, grease and shop dirt from surfaces of steel and iron parts

2 Impart a microscopic coating to surfaces that provides a base for tenacious bonding of paint and similar organic finishes

3 Prevent rust on surfaces between operations while parts or work are being held prior to application of paint, lacquer, varnish, etc.

If you are fabricating steel and iron parts for subsequent painting, varnishing, lacquering or similar organic finishes, here is a NEW development in the surface conditioning treatment of steel and iron that in ONE time-saving operation performs THREE important functions. It is known as

Oakite Compound No. 86

Designed primarily for use in metal washing machines, it (1) cleans, it (2) conditions surfaces with a microscopic protective coating that assures firm bond for paint adhesion and it (3) prevents rusting of work on parts between operations. It is SAFE to use in equipment. Extremely economical, lowers unit cost, facilitates and speeds production.

Free Special Service Report Gives Details

A FREE 3-page Special Service Report describes this remarkable Oakite development in detail, gives operating directions and other pertinent information. Write for your copy today.

press, the preliminary filtration, the subsequent hydraulic pressing and the emptying of residue from the filter chamber taking place entirely automatically. J. Hoffmann, Austria. 12-29-42.

(57) 1,987,318. Device for making up of sliced ham into rolls. F. Backenecker, Germany. 1-8-35.

(70) 2,164,245. Spindle-press or pressure exerting device of the type which includes an electric motor as a drive and wherein the driving element of the motor is preferably arranged at a permanent height with relation to the fly-wheel of the press. O. Kienzle, Germany. 6-27-39.

(71) 1,704,872. Hydaulic press for breaking metal blocks. O. Schlenstedt, Germany. 3-12-29.

(31) 2,198,440. Machine for tying a bundle of letters, books or like documents or for binding with a string one or more other objects. J. Marchand, Netherlands. 4-23-40.

(37) 2,027,657. Press for dehydrating colloid material, more particularly peat, wherein the two traveling members are pressed toward each other by one or more deformable supports subjected to the pressure of a plurality of resilient members distributed throughout their length. M. van Roggen and L. Robin, Belgium. 1-14-36.

(37) 2,052,909. Process of dehydrating colloid material. M. van Roggen and L. Robin, Belgium. 9-1-36.

(38) 2,084,229. Process for extracting juice from cut sugar beets and other gas-containing substances. D. van Maanen, Belgium. 6-15-37.

(47) 1,620,567. Apparatus for continuous extraction by pressure. P. Navarre, France. 3-8-27.

(47) 1,621,077. Three-roller sugar cane mill with a particularly arranged feed roller. A. Meesters, Dutch East Indies. 3-15-27.

(47) 2,313,996. Drum press comprising two drums which rotate in the same direction and are mounted within and eccentrically to each other. C. Hoolhorst, Netherlands. 3-16-43.

(47) 2,314,074. Turnplate for cane sugar mills consisting of a plurality of parallel ribs formed transversely of the top face of the plate, the front end of each of the said ribs

Copyright, 1944

being bevelled at the top and sides to form a tapering point terminating adjacent to the leading edge of the plate. N. Capay, P. I. 3-16-43.

(48) 1,630,430. Sieve plate for screw presses for removing water from aqueous substances, pulps, etc. K. Holter and O. Quiller, Norway. 5-31-27.

(48) 1,886,755. Screw press and the like which are used for pumping, conveying or conveying and concentrating viscous or doughy materials and the like. J. Strindlund, Norway. 11-8-32.

(48) 1,929,129. Continuous press for solid materials containing liquids comprising in combination with two rollers, usually large in diameter and rotating at a relatively slow speed, rollers in which the supporting shafts are stationary and an Archimedean screw press provided with a movable arresting disc. P. Villez, France. 10-3-33.

(48) 1,968,180. Screw press in which the material is displaced under pressure to a pressing chamber by the thread of the press screw. A. ten Bosch, Netherlands. 7-31-34.

(48) 2,104,197. Screw press adapted to press moisture and liquids out of animal and vegetable raw material and comprising an interiorily cylindrical perforate housing of uniform cross-section throughout and having an inlet or feed opening through which material may be fed into the housing. M. Johansen, Norway. 1-4-38.

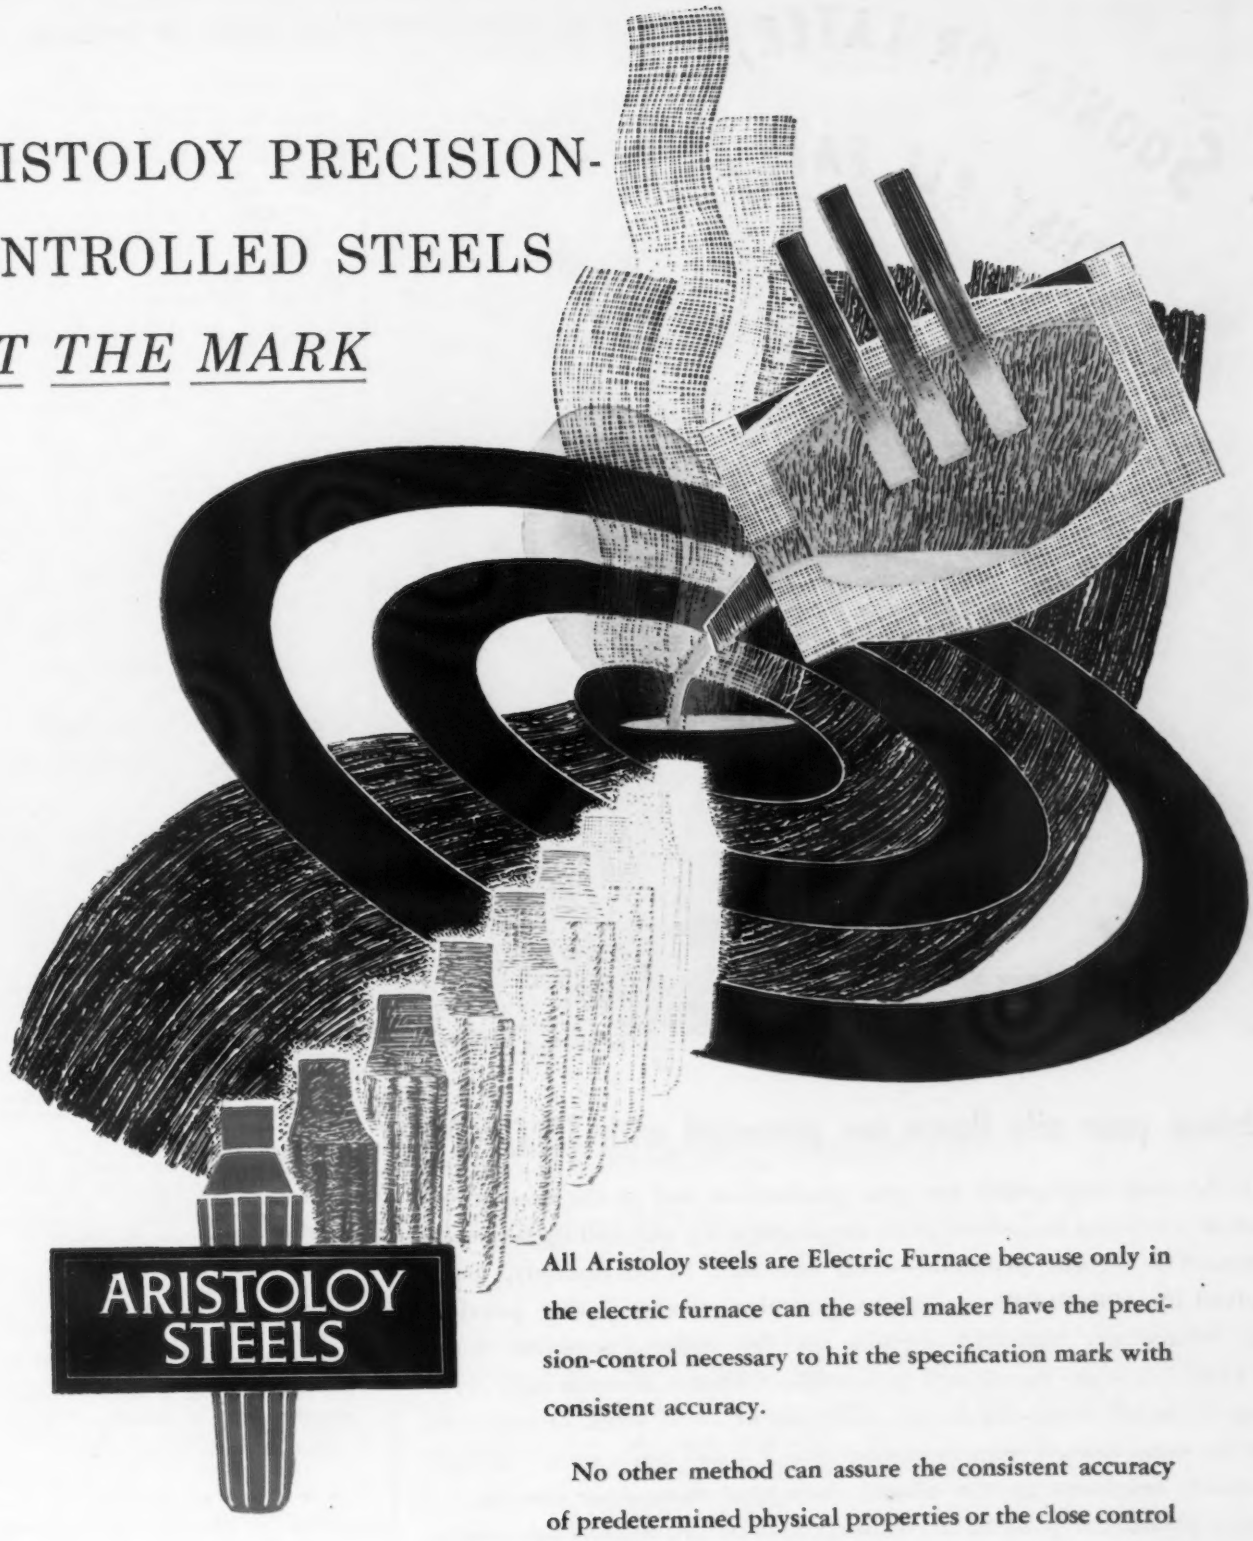
(48) 2,119,162. Screw press comprising a press casing, two longitudinal screws so arranged rotatably side by side therein that their threads intermesh with each other. H. Hartner, Norway. 5-31-38.

(48) 2,246,045. Worm press adapted for the separation of viscous resinous substances from liquids of lower viscosity and consisting of a casing and a worm rotatably arranged therein, said casing being provided with feeding and discharge devices. G. Hirschberg, Germany. 6-17-41.

(48) 2,293,297. Squeezing device for plastic and semi-plastic masses and comprising a combination of rotating worms or spindles with broad threads and has elongated channels provided for the material to be squeezed. S. Kiesskalt, K. Winnacker and K. Erb, Germany. 8-18-42.

(50) 1,724,184. Automatic hydraulically operated press for the extraction of oils from seeds or fruit in which the admission and exhaust of the pressure on the different pistons, the insertion of the filtering fabric or fabrics, the ejection of the oil cake from the

ARISTOLOY PRECISION-CONTROLLED STEELS *HIT THE MARK*



All Aristoloy steels are Electric Furnace because only in the electric furnace can the steel maker have the precision-control necessary to hit the specification mark with consistent accuracy.

No other method can assure the consistent accuracy of predetermined physical properties or the close control of chemical analyses.

SOONER OR LATER,
THEY ALL FALL!

Unless your oily floors are protected with *SPEEDI-DRI*

To the man responsible for your production and to the man whose job it is to keep insurance costs down, slipping and falling accidents present a serious problem — but one that is, fortunately, easily solved by SPEEDI-DRI — a white, granular substance that provides an immediate, non-skid surface on the oiliest, greasiest floor. SPEEDI-DRI soaks up oil and grease like a blotter absorbs ink, drawing *all* the oil (even old stains) right out of wood, steel, or concrete. At the same time, it retards fire because it won't burn even when oil-soaked; brightens up the plant; saves vital manpower needed for more productive jobs than cleaning; speeds production by making workers sure-footed. Write for literature and FREE SAMPLE.

SPEEDI-DRI
OIL AND GREASE ABSORBENT

press and the setting of the press for a new cycle of operations are automatic. L. Deoune, France. 8-13-29.

(50) 1,926,504. Process for reducing the liquid contents of materials which have many capillary spaces. A. ten Bosch Njzn, Netherlands. 9-12-33.

(51) 1,871,575. Machine for molding pressing oil seed cakes or the like, in which the seed material is pressed, for example, by means of a pressure member, into a cake mold resting on a press table. A. Aarskog and K. Svendsen, Norway and P. Ebel, Germany. 8-16-32.

(52) 2,163,839. Conveyor device for conveying molded cakes wrapped in a cloth which is automatically stripped off during conveyance, the stripped cakes being conveyed to a device for trimming their edges. A. Honig, Netherlands. 6-27-39.

(54) 1,974,697. Filter for reducing the gas or the liquid contents or both of stances which may contain many capillary spaces, for instance, for the pressing out of water and gases from peat, brown coal, of oil from oil seeds, etc. A. ten Bosch, Njzn, Netherlands. 9-25-34.

(71) 2,197,441. Hydraulic press of great power in which the principal members are made, arranged and distributed in such a manner as to permit the maximum reduction of their dimensions. J. Perony, France. 4-16-40.

(To be continued)

Central Foundries Plant Among New DPC Awards

Washington

• • • **Defense Plant Corp.**, RFC subsidiary, has authorized the following contracts:

Publicker Commercial Alcohol Co., Philadelphia, to provide plant facilities in Philadelphia at a cost in excess of $4,000,000.

Central Foundries Co., New York, the construction and equipment of a plant in Anniston, Ala., at a cost in excess of $1,200,000.

Campbell, Wyant & Cannon Foundry Co., Muskegon, Mich., to provide plant facilities at Muskegon at a cost in excess of $1,400,000.

The S. K. Wellman Co., Cleveland, to provide equipment at a plant in Cleveland at a cost in excess of $125,000.

American Viscose Corp., Wilmington, Del., to provide equipment at a plant in Lewistown, Pa., at a cost in excess of $4,000,000; equipment at a plant in Marcus Hook, Pa., at a cost in excess of $750,000; and equipment at a plant in Parkersburg, W. Va., at a cost in excess of $2,250,000.

Revere Copper & Brass, Inc., New York, to provide additional facilities at a plant in Baltimore, at a cost in excess of $900,000, making a total commitment of more than $6,800,000.

Kinetic Chemicals, Inc., Wilmington, Del., to provide equipment for a plant in East Chicago, Ind., at a cost in excess of $900,000.

Mycalex Corp. of America, New York, to provide plant facilities in Quakertown, Pa., at a cost in excess of $600,000.

• • • **The War Department** has announced the following contract awards:

Milwaukee Ordnance Plant and Signal Battery Co., Milwaukee. For conversion and adaptation of some of the existing building and utilities of the Ordnance plant and the installation of manufacturing equipment for Signal. Estimated amount of contract is $450,000. Contract awarded to Klug & Smith Co., Milwaukee. Work will be supervised by the Milwaukee district office of the Corps of Engineers.

Copher Ordnance Works, Rosemount, Minn. Award of contract to Fegles Construction Co., Ltd., Minneapolis, for dismantling portions of the works. Estimated amount of contract is $858,000. Work will be supervised by Omaha district office of Corps of Engineers.

Victory Ordnance Plant, Decatur, Ill. Contract awarded to National Concrete Fireproofing Co., Cleveland, for construction of additional facilities, alterations, and expansion. Estimated amount of the contract is $626,491. Work will be supervised by Chicago district office of Corps of Engineers.

Grinding mills used to reduce ore to appropriate size for treatment

NICKEL AIDS THE MINING INDUSTRY

to KEEP 'EM PRODUCING!

Weapons for war get their start underground.

And it's modern mining machinery that speeds 'em on their first step to Berlin and Tokio.

Through research and development work in the pre-war years, manufacturers have pioneered many innovations that make today's mining equipment amazingly efficient.

And in this war emergency, the industry is making the most of that equipment... working it harder, longer, often beyond rated capacity... spurred on by the limitless demands of war.

One reason the equipment holds up so well... thanks to the foresight of design engineers... is that many of the critical parts are made of Nickel alloyed materials.

Nickel goes a long way to make those parts longer-lasting and more dependable... tougher, stronger, more resistant to corrosion.

Hence, the use of Nickel is now so widespread that Nickel Alloys fortify nearly all kinds of mining and milling equipment parts... from drill bits and crusher frames to skips and cages, from ball mill liners to mine car axles.

Throughout the years of research and planning behind this progress, it was our privilege to cooperate with the engineers who desired help in the selection, fabrication, and heat treatment of alloys. Whatever *your* industry may be... if you'd like to have such assistance... counsel and printed data are available on request.

New Catalog Index

New Catalog C makes it easy for you to get Nickel literature. It gives you capsule synopses of booklets and bulletins on a wide variety of subjects—from industrial applications to metallurgical data and working instructions. Why not send for your copy of Catalog C today?

. . . controlling the flow of material saves man-hours and makes certain that delivery schedules will be met

On the playing fields of sport—and on the field of battle—success depends on *timing*, rhythm of motion. Timing is a vital element in production, too.

Having the right material at the right place at the right time—just enough of it and not too much — is a characteristic of efficient production.

Keeping production synchronized — timed — involves planning all along the line, to relieve congestion at one point, speed up movement at another, to the end that goods will be produced with precision and speed, and at an economical cost.

Conveyor engineering, applied like Standard does it, accomplishes all these things. If you feel that *timing* could be improved in your plant—check with Standard.

"Conveyors by Standard" — Catalog No. IA-3 is yours for the asking. Why not write today?

Distress Bearing Stocks Utilized

Washington

• • • As a result of a shortage of ball bearings, distress stocks of these products have been used to meet requirements for electric motors for the naval landing craft program, members of the WPB Electric Motor Industry Advisory Committee have reported to WPB. Government officials present at the recent meeting advised the committee that a program is now under way to provide adequate supplies of these components for motor manufacturers.

Navy officials present at the meeting indicated to members of the committee that rapid changes in future programs were anticipated, and also that heavy demands would be made for spare equipment. The industry was advised to arrange production facilities so as to be able to handle these requirements without delay.

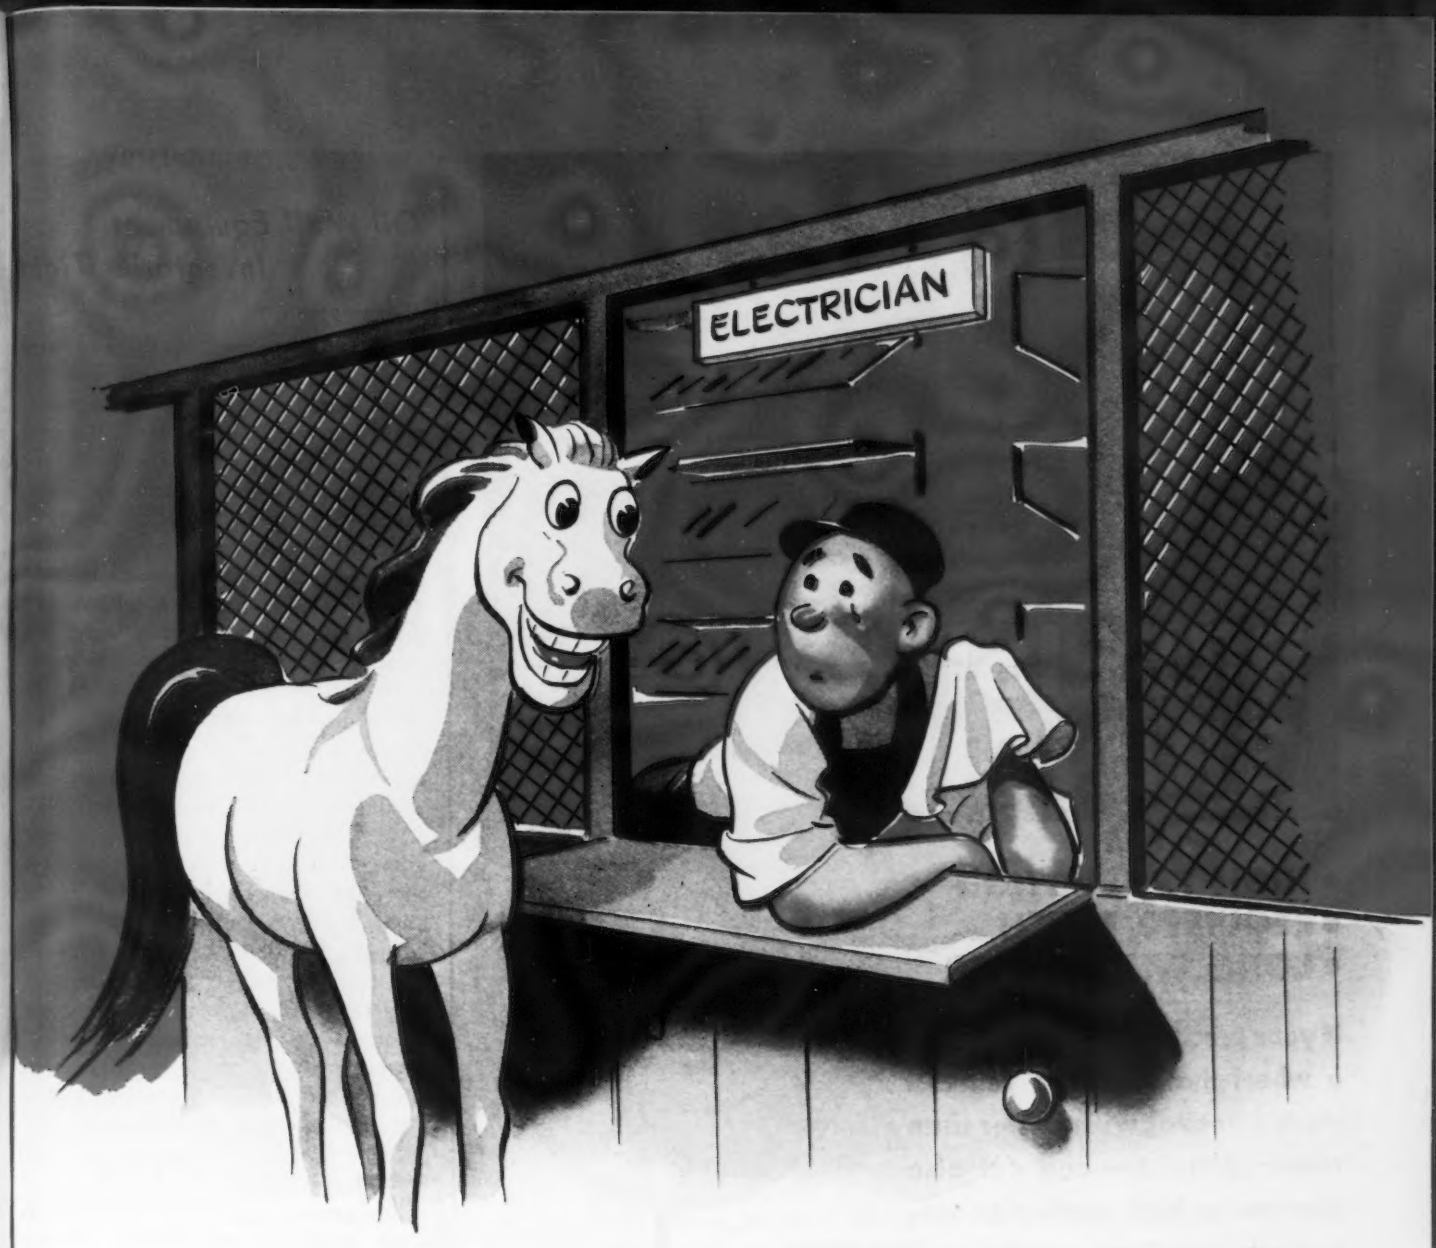
Manpower problems are becoming increasingly difficult, according to industry representatives, as key workers are absorbed by the draft. Skilled technical men, such as motor winders, electrical machinery fitters and supervisors, are being lost at a rate that threatens scheduled production of critical components such as naval DC motors, the representatives said. Industry members also reported that they are experiencing trouble in obtaining steel and malleable castings. WPB officials advised that headway is being made on easing both these problems.

OPA Puts New Price Limit On Wire Cable and Accessories

Washington

• • • OPA announced on March 13 that the maximum price for sales of wire cable, and cable accessories by wholesalers and jobbers to industrial, commercial, and governmental purchasers has been limited to 120 per cent of the manufacturer's net price to wholesalers in the same quantities. The limitation applies regardless of the number of sellers handling the product before it reaches the user.

This action, effective March 21, was taken to stop pyramiding of distributers mark-ups—a practice which, OPA said, has arisen in the industry since the war emergency. Formerly, it was possible for each seller to add to his price "average percentage margins over net invoice cost."



"Beefing" Won't Help! You need Horsepower by Howell

ELECTRICIAN: Boy, they're running me ragged. Motors coming in with no insulating varnish on 'em, and no phase insulation. Some of 'em out of balance. Doesn't take much to break those babies down.

HORSE: I know. That's why I want to tell you about Howell Motors.

ELECTRICIAN: Yeah! You better know what you're talkin' about.

HORSE: Every Howell Motor is thoroughly insulated. All our rotors are statically and dynamically balanced—they're precision-built, too.

ELECTRICIAN: Good! But do they stay that way?

HORSE: You bet they do! Good materials—copper rotors, high grade bronze or ball bearings—and careful workmanship insure long life. Ask the hundreds of Howell users in the automobile, ventilation and air conditioning industries, in dairies, grain elevators, shipyards, tank plants—they'll tell you . . . you can always depend on Howell Motors for longer, more dependable operation.

ELECTRICIAN: I know. I've used them. But we haven't got Howells here.

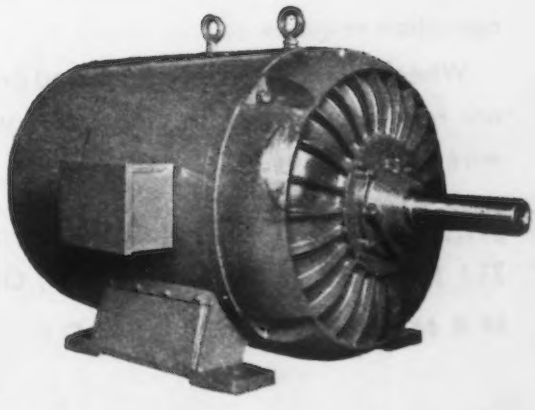
HORSE: Well, quit "beefing" and specify Horsepower by Howell for your next job.

For your specialized or standard motors, phone the nearest Howell representative today, or write the factory. Get the finest motors that money can buy at no premium in price.

HOWELL ELECTRIC MOTORS COMPANY

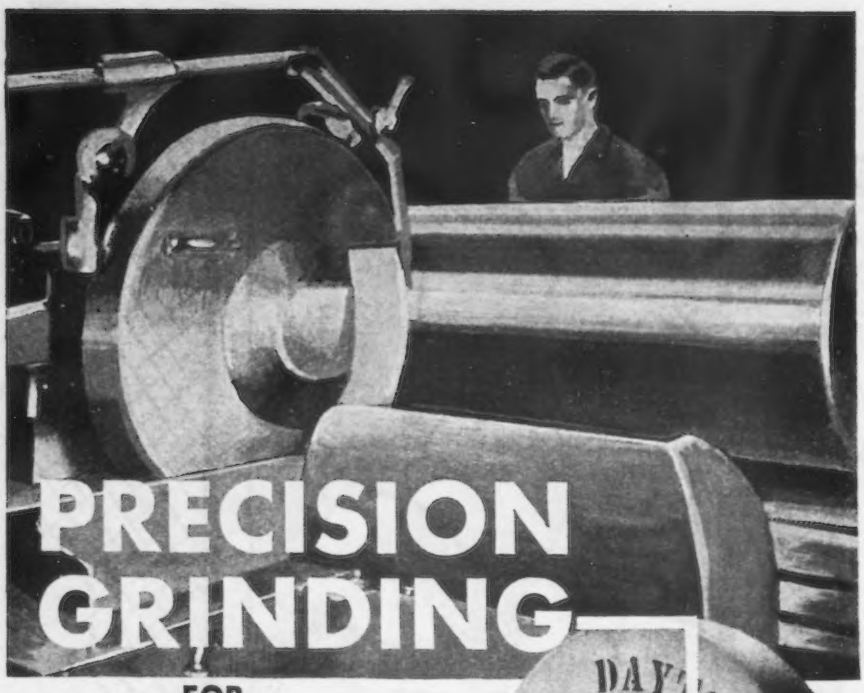
HOWELL, MICHIGAN

Manufacturers of Quality Motors Since 1915



Howell Totally Enclosed, Fan-Cooled Motor (shown above). Available through 125 H.P. . . . all working parts are protected against dust, fumes or moisture. . . . Fan cooling prevents undue temperature rise (motor overheating) . . . All steel, streamlined housing provides minimum weight and greater compactness of overall length . . . built to N.E.M.A. frame dimensions . . . special horizontal and vertical fan-cooled motors are available.

Also a wide range of other types of motors up to 150 H.P.



FOR
- HIGH PRODUCTION
- REQUIRED FINISH
- LONG WHEEL WEAR

If your precision grinding need is a wheel that will give you fast stock removal with better than required finish—and yet also give you a high production rate per wheel—then put down "DAYTON GRINDING WHEELS" for immediate trial.

You'll find Dayton Grinding Wheels have what it takes—are engineered to fit your job and to do that job precisely as the operation requires.

Wheels of many sizes, grains and grades are regularly carried in stock. Just write, wire, or phone us.

Oil Well Equipment Inventories Tight

Washington

• • • **Suppliers must** continue to carry heavy responsibility for the distribution of petroleum production equipment where it is most urgently needed, WPB and PAW officials emphasized at a recent Petroleum Equipment Suppliers Industry Advisory Committee meeting. Suppliers will be expected to maintain stocks to meet the needs of a greatly accelerated oil production program, they said, but items continue tight and no possibility of normal inventories can be realzied at this time.

Wire rope and internal combustion engines, both necessary for petroleum production, were described by WPB officials as being in extreme competition with direct military orders and therefore cannot be expected to be any more readily available at present.

Drill pipe and tool joints WPB said, are being produced at the limit of industry capacity and are going through a transition period from inadequate supply to a quantity large enough for actual operating needs. Ten million feet of drill pipe and 300,000 tool joints will be produced in 1944, WPB said.

Equipment suppliers were given much credit by government officials for their successful refereeing of operator demand with resulting favorable effect on petroleum production. Within the framework of wartime equipment shortages, petroleum production is well on its way to a wartime goal of 5,000,000 barrels a day, PAW officials said.

Scramble in Structural Market Seen by Ingalls

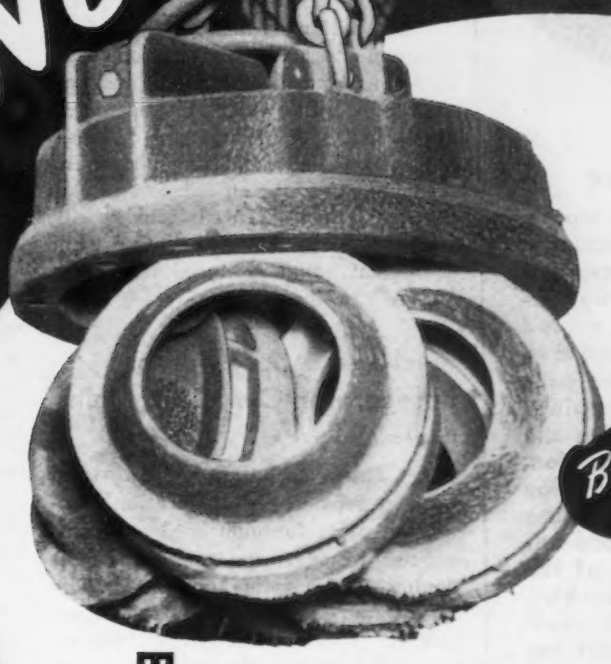
Atlanta, Ga.

• • • **A postwar** scramble for the structural steel market, bringing an era of "extremely competitive" prices in which "many of the weaker companies may fail," was forecast March 13 by R. I. Ingalls, chairman of the Ingalls Iron Works of Birmingham, Ala.

Mr. Ingalls said the structural steel industry expected a "certain amount of institutional building and a vast number of railroad and highway bridges" to be erected, but that there appeared to be no prospect of demands remotely approaching wartime schedules.

It's DINGS MAGNETS for LIFTING

YOU CAN DEPEND ON



Built to give you more

P.L.H.

POUND LIFTING HOURS

THE power, ruggedness and balanced design of every DING'S High Intensity Magnet is the result of over forty years of building magnetic equipment exclusively. The entire Dings organization is devoted to building better magnets and the engineering department is concerned only with magnetic design and operation. These years of research, testing and design have produced the DINGS High Intensity Lifting Magnet, a machine in which the balance of copper wire and steel is correctly proportioned to obtain maximum *lifting* capacity with a minimum of weight and current input.

A complete line of High Intensity Circular and Rectangular lifting magnets, to meet every requirement, is offered to those with metal handling problems.

For complete information and CATALOG, write today.

WORLD'S LARGEST EXCLUSIVE BUILDERS OF MAGNETIC EQUIPMENT

STRENES METAL
IN FRONT LINE OF SERVICE

BEFORE THE WAR

Strenes can be cast to shape. Most of the usual machining time is saved. Redressing is reduced. That is why before the war Strenes gained heavily as forming and drawing die metal. In one case around 2,000,000 stampings were obtained and the die is still in good condition, ready to resume operation at the end of the war. Runs of 100,000 pieces up are not uncommon. Hundreds of the largest plants in the country used it regularly in their tooling programs. Want the names of pre-war users of Strenes?

IN THE WAR

Strenes today is being used for draw pots, draw pot inserts, draw rings for draw bench operation, for progressing upsetting dies — all in shell manufacture. Glad to identify all such users and many others.

AFTER THE WAR

After the war, refrigerator, stove, metal casket, grave vault, farm implement and other manufacturers will resume with Strenes metal forming and drawing dies. Many of the automobile, truck and tractor builders are extensive users, for body, fender and hood dies. Will name them to interested inquirers.

Look into the merits of Strenes metal — Try it, at least once.

DAYTON 3, OHIO

Copper Use for Fasteners Approved for AA-3 Orders

Washington

• • • **Sew-on, machine** attached or riveted snap fasteners, buckles, eyelets, staples, rivets, and burrs may be manufactured from copper if they are for military use and if they are purchased on orders bearing AA-3 preference ratings or better, WPB announced.

This action, which is taken by amendment 2 to conservation order M-9-c as amended Jan. 22, replaces a former rule which restricted the manufacture of these items to those for use on jungle clothing and equipment, and for use on leather, canvas, webbing, duck, coated fabrics and special fabrics for field clothing and equipment being produced on ratings of AA-3 or higher.

Steel Use Approved for Refrigerator Condenser Units

Washington

• • • **The WPB on March 10** revoked specifications for refrigeration condensing units for industrial and commercial refrigeration and air conditioning machinery and equipment. The most important feature of the action was the removal of the prohibition on the use of steel in the construction of bases for refrigeration condensing units having motors over 20 h.p. in size. Revocation of this restriction, WPB said, will save valuable manhours formerly required to erect concrete bases at the time of installation of the unit. The original purpose of this provision was to conserve steel, but now that the type of steel required is generally more available, it is considered more important to conserve manpower.

WPB's action which revoked schedule II to order L-126 also removed standardization restrictions which limited the number of models that each manufacturer could produce. Since a large percentage of the units now being produced are for military use and since those produced for the Army, Navy and Maritime Commission were exempted from model standardization, it was felt by WPB that these restrictions were no longer necessary.

Alloy Steel Use Permitted In Hand Tool Manufacture

Washington

• • • **WPB announced** on March 10 that alloy steel may be used in the manufacture of items covered by schedules I, II, IV and V of the hand tools simplification order, L-157. As amended, the schedules will allow manufacturers to use alloy steel instead of carbon steel if they desire. In some cases this will result in the production of a better product.

Items covered by the schedules, which establish simplified practices and limit manufacture to the types, sizes, etc., specified, follow:

Schedule I — hand shovels, spades, scoops, and telegraph spoons; *Schedule II*—forged axes, hatchets, broad axes, adzes, and light hammers; *Schedule IV* — heavy forged hand tools; and *Schedule V* — hand forks, hooks, rakes, hoes, eye hoes and cultivators.

"Sure are doing everything to discourage travel, aren't they?"

U.S. Steel Output in 1943 Totals 30,540,000 Net Tons

New York

• • • In its annual report to stockholders, the U. S. Steel Corp. announced that steel production by the Corp. in 1943 totaled 30,540,000 net tons of ingots, a new production record, and the production for the three-year period, 1941-1943, totaled 89,500,000 tons. Finished steel shipments totaled 20,148,000 net tons. The Corp. is now operating steel mills, some of which belong to the government, which will have, when completed during 1944, an annual ingot capacity in excess of 33,800,000 tons. To develop the company-owned facilities, since 1929 the Corp. has spent or authorized for expenditure about $1,050,000,000 of its own funds.

In the renegotiation of contracts for the 14 U. S. Steel subsidiary companies, the Navy Price Adjustment Board, acting for all governmental agencies, completed renegotiation of 13 companies and found them to have realized no excessive income up to Dec. 31, 1942. The renegotiation with the remaining subsidiary, Federal Shipbuilding and Dry Dock Co., resulted in a reduction of $3,000,000 in the selling prices of deliveries under Navy Dept. contracts up to Dec. 31, 1942. This amounted to an actual refund of $570,000, reported as a reduction of income for 1942.

Federal Shipbuilding delivered from its Kearny and Port Newark, N. J., yards 80 ships, including destroyers, destroyer escorts, transports, and Naval auxiliaries.

Concerning strikes, it is reported that the U. S. Steel's production performance was made possible by effective cooperation on the part of employees, and only the action of small groups in bringing about a series of strikes and work stoppages marred this record. These strikes resulted in an estimated loss of steel production of 318,000 tons, compared with 53,000 tons in 1942; a loss of coal output of 2,600,000 tons compared with 32,000 tons lost in 1943, and a loss of 4,845,000 man-hours as against 267,000 man-hours similarly lost in 1942.

Concerning the CIO-USWA proposals for a wage increase of 17c. an hr., and other benefits, now pending before the War Labor Board, U. S. Steel estimates that if all proposals were accepted and applied to all subsidiaries having CIO contracts, manufacturing costs at present operating rates would be increased $186,000,000 a year.

The U. S. Steel Corp. income for 1943 totaled $63,448,546, as against an adjusted income for 1942 of $71,248,569. The adjustment in 1942 income resulted from renegotiation of contracts. Net sales for 1943 totaled $1,976,844,751 as against $1,862,951,692 for 1942 after adjustment. While sales during 1943 were 6.1 per cent higher than in 1942, net profit was 10.9 per cent less. The profit margin based on net sales for 1943 was 3.2 per cent, whereas for 1942 it was 3.8 per cent.

ASME to Meet at Birmingham

Birmingham

• • • An address by Maj. Gen. G. M. Barnes, chief, technical division, Office of the Chief of Ordnance, Washington, on "Keying Research to Battle Problems" will be one of the highlights of the 1944 spring meeting of the American Society of Mechanical Engineers to be held here April 3, 4, and 5.

On the convention agenda are such topics as management, aviation, fuels, industrial instruments, and metals engineering.

COMING EVENTS

March 27, 28—American Society of Tool Engineers, Philadelphia.

March 30, 31—American Gas Association War Conference, Rochester, N. Y.

April 2 to 5—The American Ceramic Society, Inc., Pittsburgh.

April 5, 6, 7—SAE National Aeronautic Meeting, New York.

April 12 to 15—The Electrochemical Society, Inc., Milwaukee.

April 17, 18—American Zinc Institute, St. Louis.

April 25 to 28—American Foundrymen's Association, Buffalo.

May 1, 2—Westinghouse Machine Tool Electrification Forum, Pittsburgh.

May 8—Association of Iron & Steel Engineers, spring conference, rolling mill committee, Pittsburgh.

May 9, 10—American Steel Warehouse Association, Inc., Chicago.

May 25—American Iron and Steel Institute, New York.

By any light . . . in any age

BRASS

IS ALWAYS MODERN

WHEN whale oil lit the evening reading tables of 1807, it glowed from burnished brass lamps . . . symbols of civilized living that lit the way forward from the smoky hearths and pine tapers of log cabin days. And fifty years later, when kerosene became plentiful, brass lamps with brass burners and fittings became more firmly ensconced than ever as modern home lighting fixtures.

Today, more than 130 years after the whale oil lamp . . . nearly 2,000 years after the first rude lamplight shed its rays over delicately wrought Chinese brass . . . this ageless alloy is still among the foremost of the modern metals for smart lamps and lighting fixtures. And why? Two reasons. One, because homeowners and decorators have never found another metal that gives the same golden-yellow richness and cheerful gleam of brass. And the other, because brassware fabricators have never found another metal that is so easy to machine and form into so many products. So it is safe to say that 100 or 1,000 years from today, brass will still be modern . . . because it will always be the classic of its kind.

Here at Bristol, brass of many different analyses has been rolled and drawn for a multitude of uses . . . industrial, functional, and decorative . . . though today it all goes to munitions makers to rid the world of Huns and Japs. When that job is done, then Bristol will turn to the job of helping modern-minded manufacturers win new peacetime victories with Brass, the modern metal. And it's not too early to talk things over, right now.

THE

BRISTOL BRASS

CORPORATION

Makers of Brass since 1850, Bristol, Conn.

Measuring Errors in Involute Spur Gears

(CONTINUED FROM PAGE 73)

the most rapid forms of complete inspection, and the second type involves the use of the least expensive equipment. The second type is often sufficient for completely inspecting gears where profile errors are not critical.

To use a pin to determine *pitch-line runout* the gear is usually mounted on centers, and the variation in the highest position of a pin of convenient size in the tooth space is measured with an indicator as the pin is moved from space to space around the gear. Two pins are sometimes used with a micrometer without mounting the gear on centers, but as this has no reference to the axis of rotation, it will indicate only the *out of round* type of distortion and local errors. Cone checking fixtures are a convenient and somewhat more rapid way of checking runout. On this type of fixture, the gear is also mounted on centers. A slide, mounting a cone attached to an indicator, is so arranged that the cone can be rapidly inserted in each tooth space and the variation in the distance to center determined from the indicator readings. This type of fixture is also adapted to the use of the ball, rack tooth, or rack space.

In using any of the double-sided inspection methods, it should be kept in mind that the larger the operating pressure angle between gear and master, the larger the diameter of the pin, the greater the included angle on the cone, rack tooth, or rack space, the less sensitive will the readings be to local distortion of the gear. However, a displaced ideal gear will show the same runouts as long as contact is maintained with the involute regardless of angles or diameters. Thus with *double-sided* methods of inspection, standards for testing conditions should be set up so that results will be comparable.

Red or blue lead is sometimes used on a hand-rolling fixture with the tightly meshed master gear method and is reliable except to the extent where center distance variation affects the depth of the tooth bearing. Operating speeds and pressure are of course not obtained. The same hand-rolling fixture may be used to check bearing on standard center distance with backlash between the gear and mate or master. This method is not double-sided, but neither is it truly functional as speed and pressure cannot be made to approach operating conditions.

Best Methods of Inspection

All the types of inspection mentioned herein have been used successfully. If a complete picture of gear quality is to be obtained, provision to check functional or double-sided methods against fundamental methods should be had. This means that involute measuring machines, spacing checkers and taper checking equipment should be available. For efficient and complete quality control, the power testing method has many advantages if both visual and audible techniques are used. All errors on all teeth manifest themselves to the operator in a very short time if he knows how to interpret the signs. The disadvantage of this method is obviously that a skilled operator is essential. The method of inspection using tightly meshed gear and master will detect most combinations of profile and spacing errors but it will not permit accurate evaluation of these. A master gear should be used rather than a mating gear as the mating gear will tend to operate on too short a center distance when tightly meshed. Runout can be determined without the expense of a master gear by using a cone checking machine or a pin and indicator. The advantage of the master gear is that it is somewhat faster. It should be remembered that the double-sided methods do not check lead, and so if high quality gears are required, some supplementary check for parallelism should be employed.

In the actual selection of checking equipment, the most important factors to bear in mind are volume of gears to be inspected and quality to be maintained. The chart, Fig. 6, shows a possible selection of equipment to meet various conditions. It does not cover equipment for measuring backlash, root radius or other factors not directly affecting action.

Among the Week's Trade Notes

Monsanto Chemical Co., St. Louis, has announced a contract by which it will acquire I. F. Laucks, Inc., of Seattle, manufacturing chemists and producer of plywood glues. Through the transaction, Monsanto will acquire the two Lauck plants in Seattle and other company interests at Vancouver, B. C., Los Angeles, Portsmouth, Va., Lockport, N. Y., Stanbridge, Que., and interests which Laucks holds in Australia and Sweden.

●

Electric Service Supplies Co., Philadelphia, will hereafter be known as Electric Service Mfg. Co. The company's personnel, ownership and manufacturing remain the same.

●

S. F. Bowser & Co., Fort Wayne, Ind., has purchased the Eagle Lock Co., Terryville, Conn., for two million dollars. The purchase is subject to stockholder approval.

●

E. I. du Pont de Nemours and Co., Inc., Wilmington, Del., has taken option to buy an 822-acre site containing the San Jacinto shipyard property of the U. S. Maritime Commission, near La Porte, Tex.

Greeman Steel Treating Co., Worcester, is using acetylene torches, with setup a most important part of the operation, in a new flame hardening process for delicate metal parts or where localized hardening is necessary.

●

Walton Industries, a subsidiary of Walton Die & Mold Co., Detroit, has purchased the six-story building at 28 Ionia Avenue, S W., and plans to begin manufacturing operations shortly with a payroll of around 40 persons.

●

Pennsylvania Transformer Co., Pittsburgh, announces the appointment of J. J. Costello Co. as sales representative in New England territory with offices in Boston, and New Haven, Conn. J. F. Joyce has been appointed district sales representative with offices in Cleveland.

●

B. F. Goodrich Co., Akron, Ohio, has awarded a construction contract to the George A. Fuller Co., Washington, for the buildings which will house a new tire manufacturing plant to be erected in Miami, Okla.

●

Auto-Ordnance Corp., maker of the Thompson submachine gun, has changed its name to Maguire Industries, Inc., because contemplated postwar activities will have little relation to ordnance.

●

Norman Bel Geddes has dissolved the partnership that he formed in 1943. The company will continue under his personal direction, keeping the name Norman Bel Geddes & Co. The entire sales department has been eliminated.

●

Lamson & Sessions Co. has moved its Chicago sales office from the plant to Room 1710, 310 South Michigan Avenue, Chicago 4.

●

Sprague Specialties Co., North Adams, Mass., is to erect a special type building for commercial process work in connection with the manufacture of condensers for the Navy.

●

Worcester Pressed Steel Co.'s munition work includes a pressure vessel or bottle designed from a 100-lb. forging that must function at a working pressure of 750 lb. per square inch and test at 3100 lb. pressure.

●

Leon J. Barrett Co. has devised a special centrifugal machine for making cases for covering condenser coils. It has stepped up production of steel cases from 50 to 5000 per hr. Condenser coverings originally were of copper or brass, but when these metals became scarce were made of steel, plated with copper or tin.

●

United States Rubber Co.'s wire and cable department has taken over plant No. 1 of the Lowell, Mass., Ordnance Works and will manufacture a long line of communications cable for the Signal Corps.

NO...IT'S REALLY pH THAT DOES THE CLEANING!

THE "CURE-ALL" is a great idea—but it won't work. Today, in your business and in ours, we know that it takes a "specific" to make a cure or get a job done right.

One Does The Work Best

In every processing and cleaning operation there is one specific chemical combination which precisely fills the requirements of a particular situation and will do the job best. The difference between this correct material and anything else — even the closest approximation—is extreme. Kelite sees it every day in reports from Service Engineers in the field. You can see it in the unequalled speed, certainty and economy which the correct material makes possible.

pH Simplifies The Job

This matter of the right material for the job is so important that Kelite has gone to great lengths to attain it. Formerly, standardized test tubes of correct solutions were made up in the laboratory and used as models on the job. All this work was worth while, but it was slow... until we learned how to make use of pH. Now it's simple!

No Special Skill Needed

An operator does not have to be skilled to use Kelite pH Control. The pH values are lined up and compared in an easily-understandable form on the Kelite pH Chart. It's as easy to use as a yardstick! Your inquiry is invited.

Ratings Needed for Reconditioning

Cleveland

• • • **Machine tool reconditioning** and re-tooling by the original builders has recently taken on increased importance. It has also taken on certain controversial aspects which vary between individual producers.

Most recent entrant into the field has been the National Acme Co. which is actively soliciting orders to completely recondition and re-tool any of its machines within the 10 to 15 yr. age span. The re-tooling phase of the program is being emphasized because a large number of machines particularly from the munitions field are becoming available for other production and for those manufacturers who can see their way to planning future production, this is an opportunity to re-tool in advance of actual need.

While there is need to recondition a large number of machines due to the overloads and abuse sustained during war production, there are a number of arguments presented against machine tool builders engaging in such pursuit. One of the most formidable of these is the fact that a great many of the rebuilding jobs available tend to come into the builders' shops without a rating. This in effect, causes the builders to expend man-hours and material on unrated work. This is difficult to avoid as many of the firms considering having machines reconditioned do not wish to take the trouble to obtain ratings, although they are available.

Contradictory as it seems it is also true that the workings of the current Internal Revenue Act will not permit allowance for the costs of rebuilding machines unless a rating is obtained. This should influence some machine owners to obtain ratings so that the charge may become a capital goods investment.

There is also some criticism of the policy behind reconditioning older machines which will only serve to glut the post-war market for machine tools worse than now appears likely by removing most rebuilt tools from the strictly obsolete class.

It is reported that there is a currently confidential report of idle machine tools soon to be issued by the WPB which will reveal the vast number of relatively new machine tools available. While no estimates of this survey's total can be made yet, it is known that several hundred thousand such machines are actually idle at this time. Some of the most far thinking members of the machine tool industry point to the fact that this pool of available tools represents the newest products of the industry for the most part and seem to represent the best outlet for any builder's ambitions to do reconditioning. A definite move to remove the old "hookers" from the scene and supplant with these newer machines seems sure to come a little later.

The position, however, of each individual builder with regard to rebuilding its own models differs greatly in that some have not made drastic revisions in models over the past 10 years and little could be gained by restricting rebuilding to only latest models.

CASTING DWARFS MACHINE: *Machining of this 45-ton warship propeller strut poses a difficult problem, with one 15-ft. arm sticking up in the air. Surfacing of one attachment pad is being performed on this big planer at a Kearney, N. J., shipyard by the use of an extended tool holder pedestal mounted on the standard clapper box.*

•

Order Volume Compares With 1936-38 Level

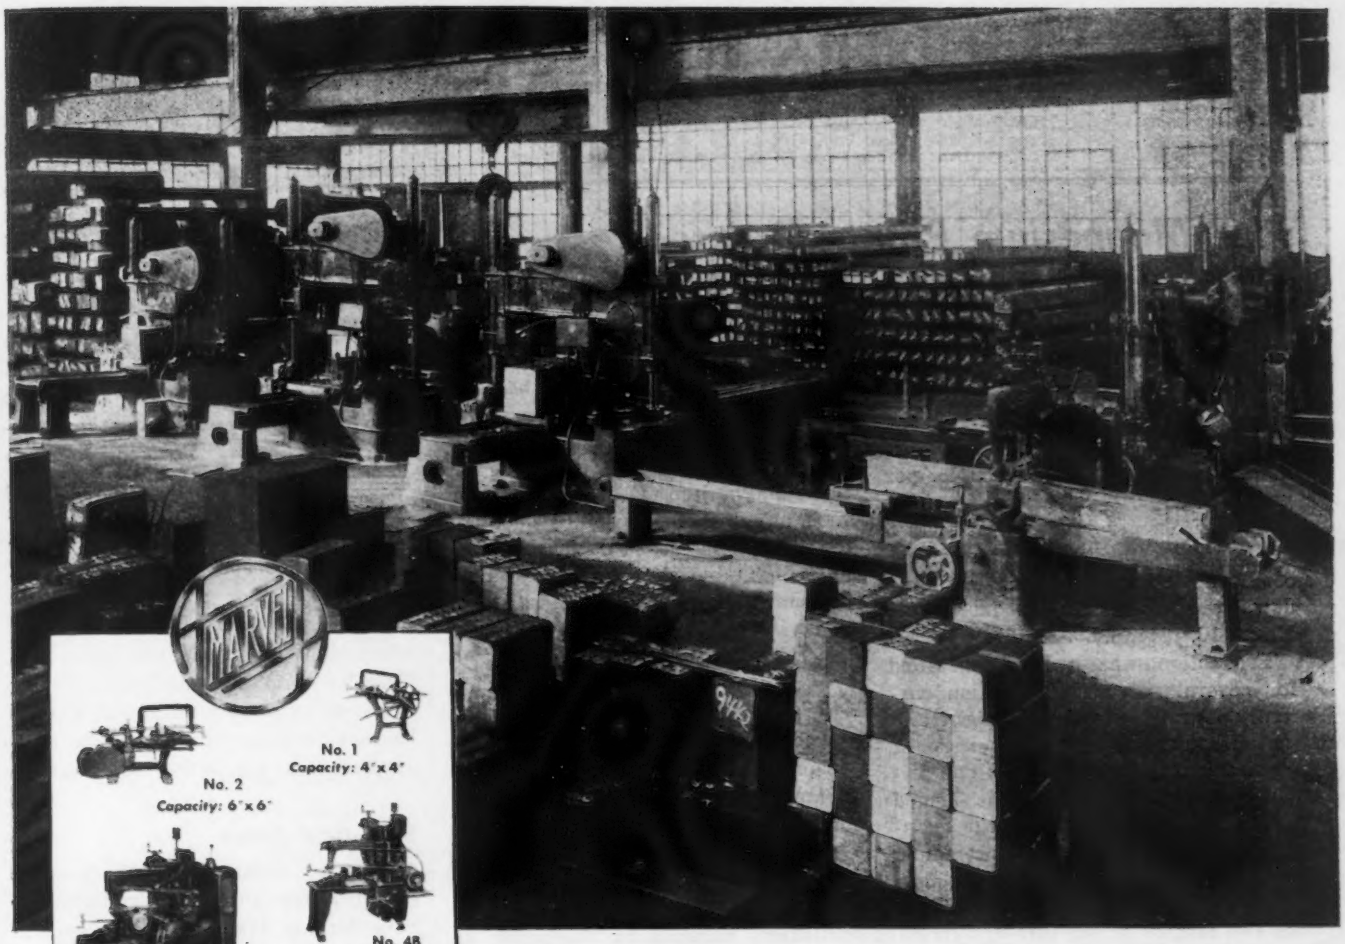
Chicago

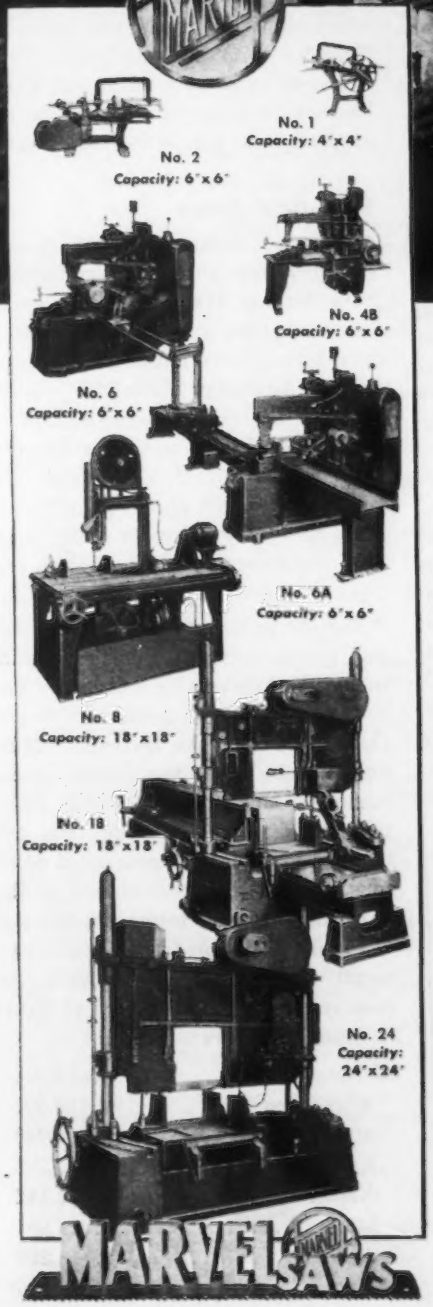
• • • **Current machine tool** volume is compared by local dealers to 1936 and 1938. Tailend orders from war plant tooling up continue to dribble in and these, combined with sustained normal buying from such civilian industry as the railroads, provide a comfortable business level for dealers in new tools. For future months, it is anticipated that buying for railroad shops indicated by current inquiries will provide a comparatively large number of orders from that industry. One huge aircraft engine plant, apparently neither fully tooled nor fully manned, still is in the market.

Design modifications in war equipment have not been of such a nature as to require much buying of new basic tools.

Among machine tool builders, a far greater degree of conversion to production of direct war products is noticeable than six months ago. At that time, conversion was chiefly noticeable among the smaller manufacturers, but some of the industry's biggest firms now are turning out a substantial volume of war goods.

With random exceptions for certain specialized machines, manufacturers' backlogs on larger tools cluster in the four to six months range, and on smaller tools, from 45 to 90 days.





2 men now do the work of 4 and save forging steel too

The Ajax Steel & Forge Company, Detroit, has solved its cutting-off problems with a battery of MARVEL Saws. Before, billets were cut-off with a hammer—an operation which not only required at least four men and tied up hammers and furnaces, but also resulted in the waste of a great deal of forging steel.

Now two operators with seven Marvel Saws supply the entire plant with billets cut to exact size from bars up to 18" x 18" square. In addition to their present Marvel Saws, five of which are illustrated above, this company is adding a super-giant MARVEL No. 24 Hydraulic Hack Saw—the new mammoth saw that quickly cuts off the toughest steels in sizes up to 24" x 26" cross section.

Our local MARVEL Sawing Engineer will gladly call at your plant, study your metal cutting problems and make recommendations as to methods and equipment. Write for new Catalog.

Five Magnesium Plants Ordered To Curtail or Stop Production

Washington

• • • **WPB ordered reductions** in magnesium production at five plants. With total rated capacity of all plants in the country at 586,000,000 lb. per year, reduction will amount to about 33,750,000 lb. per year or less than 6 per cent of capacity. Announcement of Ford magnesium plant shutting down was made in THE IRON AGE, March 16, 1944, p. 80.

Production was ordered curtailed for several reasons. Production currently is running between eight and ten million lb. per month in excess of requirements. This surplus is due primarily to the fact that the armed services have not consumed the quantity stated in their requirements. Surplus stocks of magnesium now total more than the amount required for two months at the rate of current consumption. Furthermore, this action will result in savings of coal, gas, transportation, and labor in areas where one or all of them are scarce.

Only one of these plants, Permanente Metals Corp., has been operating at capacity. Therefore, curtailments will be less drastic than appears from the rated-capacity figures. In the case of Electro Met, for example, the order will merely freeze production at 50 per cent of rated capacity or slightly more than the present rate. Practically the same thing will be true of Amco.

Magnesium is being released by WPB for all possible military requirements and for essential civilian needs. Greater utilization of magnesium products by the military has been encouraged by WPB for some time. Restrictions for all civilian purposes cannot be removed at this time because magnesium fabricating facilities such as foundries, are not adequate for other than essential demands. The following table shows January, 1944, production, cutback effected, and labor saved in the five plants affected.

•

Zinc Limitations Eased

The WPB has announced its provision for the restoration of the use of zinc in the manufacture of many finished products. The restoration was effected by amending Conservation Order M-11-b to add a number of items to the list of exceptions to the limitations imposed by the order, as follows: Coal stokers, domestic electric ranges, dry cell batteries and portable electric lights, electric fans, mechanical pencils, motorized fire apparatus, protective coating or plating of zinc on loose leaf metal parts and units.

There will be no general increase in the output of the finished products involved, nor will there be any relaxation in the restrictions on the manufacture of the products, WPB said. End product volume and other restrictions on manufacture still remain under the controls set up by the many "L" orders under which they are produced.

REDUCTIONS IN MAGNESIUM OUTPUT ORDERED BY WPB

COMPANY	Process Used	Annual Capacity, Lb.	Reduction Ordered, Per Cent of Capacity	January Production, Lb.	Monthly Reduction, Lb.
Electro Metallurgical Co., Spokane, Wash.	Ferrosilicon	48,000,000	50	1,500,000	0
Permanente Metals Corp., Manteca, Cal.	Carbothermic	20,000,000	50	1,880,000	940,000

Mathieson Alkali Works, Inc., Lake Charles, La.	Mathieson	54,000,000	100	955,000	955,000
Amco Magnesium Corp., Wingdale, N. Y.	Ferrosilicon	10,000,000	35	424,000	0
TOTAL		172,000,000	22	5,722,000	2,814,000

Canadian Aluminum Price Down

Toronto

• • • **C. D. Howe, Minister** of Munitions and Supplies, announced that Aluminum Co. of Canada has reduced the price of aluminum "by agreement between the company and the Canadian Government." The reduction also applies to purchases from the company by the United States and the United Kingdom. The Minister, however, did not specify the amount of the reduction nor give information as to the new price. Local officials of Aluminum Co. of Canada state that they have no information regarding the new price and point out that it has not been passed along to the ordinary trade as far as they are aware.

•

Statistical Notes

• **The net consumption** of silver in industry for 1943 was reported to have totaled 118 million oz., according to figures submitted at a recent Silver Producers and Distributers Industry Advisory Committee meeting. Imports of ore and base bullion and refined silver amounted to about 63 million oz. and United States mine production added about 40 million oz. The deficiency between new supply and requirements was supplied from Treasury free silver.

• **For the first month** of the year, copper production from domestic mines including Alaska was 89,506 net tons, a decrease of 1288 tons from that in December, 1943, the Bureau of Mines announced. For the same period, domestic zinc mines yielded 64,894 tons, an increase of 1020 tons over the previous month's output of 63,874 tons. Mine production of lead in January increased 409 tons to 38,325 tons.

• **Figures on non-ferrous** secondary metal recovered in 1942 have just been released by the Bureau of Mines. In brief these are:

Secondary Metal	Net Tons
Aluminum	198,492
Magnesium	6,238
Copper	927,755
Nickel	4,142
Lead	323,001
Antimony	18,200
Zinc	330,526

WPB Tries to Bolster Up Weak Scrap Market by Warning of Shortages

New York

• • • **Considerable criticism** has been forthcoming from WPB circles of reports that various grades of scrap are going at lower than ceiling prices and that some grades are not moving at all. The shortage of carbon grades, as emphasized by the WPB Industry Advisory Committee, may, on the whole, be true for a long range picture, but actual current shortages are difficult to locate. Furthermore, there seem to be no mills particularly anxious about any possibility of a coming severe scrap shortage.

Many mills have been reported from time to time as being completely out of the scrap market for periods varying from a couple of days to several weeks. This would indicate that no particular anxiety was felt by mills for scrap supplies.

Why WPB should continually try to bolster up a weakening scrap market seems pretty obvious. To let down on efforts to get out the scrap might result in a scrap shortage, and any wholesale breakdown of the scrap price structure would tend toward this end. To prevent such an occurrence, WPB's efforts have not lagged.

There have been charges from time to time that mills are trying to break scrap prices. There's a belief in some quarters that one of the large eastern consumers is very energetic along this line at present. On the surface, any current concerted effort by the mills to break the scrap market doesn't seem to make sense, because of the industry's efforts to obtain higher steel prices. The fact that mills are at present curtailing buying doesn't necessarily indicate they are trying to break the market, but more likely seems to point to the fact that a semblance of normal economics is beginning again to function in this inflated war period and mills are endeavoring to bring stocks more in line with consumption.

There was a definite trend this week toward sales closer to ceiling prices rather than toward more widespread under-ceiling sales. Most districts reported that in-district sales were holding to ceilings, while some out-of-district sales were being made sufficiently lower than the ceiling so as to absorb the freight from the point of sale to the point of consumption.

Some grades of scrap are just not selling. For example, blast furnace scrap at Cleveland doesn't have a market, but observers believe that when this grade begins to move again it will be at a price at least $1 below the ceiling. However, out-of-district sales from Cleveland of blast furnace scrap at lower than ceiling have been reported, indicating the weakened market at that center. This is true of several other specific grades, and, while sales in Cleveland under the ceiling are not being made, these low out-of-district sales will affect the local market when buying resumes in that area.

•

PITTSBURGH — Supply and demand still in balance. Most of the weakness, price-wise, on turnings from outside this district, has disappeared, temporarily at least. Other grades firm at ceiling.

•

CHICAGO—Sales are reported to mills of short shoveling turnings at $13.75; of cast iron borings at $12.75; and of mixed borings and turnings at $12.75. Sales of machine shop turnings also are reported at $1.75 below ceiling. Other open hearth grades appear to be firm with some West Coast shipyard scrap still to be delivered here under commitments made several weeks ago. In the matter of alloy residuals, one mill complains of difficulty with tin, but this is not believed to have been due to tin cans. Much difficulty with chromium, nickel, and molybdenum as residuals in material sold as carbon steel scrap continues, and the situation promises to become worse unless some real solution is found for disposal of triple alloy scrap.

•

PHILADELPHIA — Several mills that have been holding up shipments have lifted restrictions either in whole or in part. However, it is the opinion of some suppliers here that should all restrictions be lifted, the quantity of heavy open hearth grades could not be increased to meet greater demand. Low phos which had been selling at below ceiling prices is now practically impossible to move even at cut-rate. Both open hearth and foundry grades of cast scrap continues to be difficult to find.

BOSTON—With shipyard scrap allocated, little battlefield coming into New England, and natural local sources of scrap picked to the bone, coupled with a labor shortage, most yards are "existing," while brokers are able to get only an occasional car of material.

•

CINCINNATI — The situation here seems to be fairly well balanced as dealers indicate there is a reasonably ample supply of open hearth scrap and turnings. Some pressure to stop diversion of open hearth scrap to electric furnaces is reported. Cupulo cast continues to be tight, although no stringency has yet been reported. Sale of scrap for consumption within the district continues at ceiling, but some out of the district material, particularly on turnings is running $1 to $2 under the ceiling prices in Cincinnati for shipment into other districts. Consumers there refuse to pay a price which will cause them to absorb the additional freight.

•

BIRMINGHAM—Demand is practically non-existent here for any grades of material except open hearth grades. Despite lack of demand, prices are holding steady.

•

LOS ANGELES—In addition to allocations of shipyard scrap to Chicago district buyers which still continue, quite a volume of scrap is moving to Utah for the Geneva mill's priming charges. In southern California No. 1 and No. 2 heavy melting and No. 2 bales are reported at $1.00 off dealers' price and mills may reduce their offers another dollar this month. Prices are reported a little firmer in the Pacific northwest though ceilings in that area are lowest in the United States. Cast scrap continues at ceiling with scant supply.

•

BUFFALO—Mills appear to be amply supplied, with the largest consumer continuing to receive outside scrap under allocations. Very little dealer scrap is reported. Consumers apparently are shying from increasing inventories; in fact, are whittling down stockpiles. Conflicting reports of shortages and surpluses have left district dealers groggy. Nevertheless, most items are moving fairly well.

•

ST. LOUIS—Heavy snow in the area early in the week slowed down shipments to the district's mills. The main factor, however, in the movement of scrap both to and through the yards is the manpower available to handle and prepare it. Even the handling of railroad scrap is said to have slowed down because of labor shortages.

* Baled turnings are $5 per gross ton higher.

BUNDLES: Tin can bundles are $4 below dealers' No. 2 bundles; No. 3 bundles are $2 less than No. 1 heavy melting.

AT NEW YORK CITY or Brooklyn, the maximum shipping point price is $15.33 for No. 1 heavy melting, f.o.b. cars, f.a.s. vessel or loaded on truck. Minimum set at $14 per gross ton at any shipping point in U. S. Other grades carry differentials similar to those in table. New Jersey prices must be computed on basis of all-rail. At Boston the maximum is $15.05 for No. 1 f.o.b. cars, f.a.s. vessel or loaded on trucks. Shipments from a New England shipping point to a consumer outside New England carry maximum transportation charge of $6.66 per ton.

SWITCHING CHARGES: Deductions for shipping points within basing point (cents per gross ton) are: Chicago, 84c.; Pittsburgh, Brackenridge, 55c.; Detroit, 53c.; Midland, Johnstown, Sharon, Youngstown, Warren, Weirton, Cleveland, Toledo, Los Angeles, San Francisco, Pittsburg, 42c.; Seattle, 38c.; Buffalo, Claymont, Harrisburg, 36c.; Atlanta, Birmingham, 32c.; Butler, Monessen, Canton, Steubenville, Cincinnati*, Portsmouth, Ashland, Coatesville, Phoenixville, Bethlehem, Kokomo, Duluth and St. Louis, 28c.; Alabama City, Ala., 26c.; Minnequa, Colo., 22c.; Middletown, 14c.; Conshohocken, Sparrows Point, 11c.

*Basic open hearth and foundry grades, and auto springs and crankshafts, deduct 80c. per ton.

BASING POINT includes switching districts of city named.

Basing point	Switching districts:
Pittsburgh	Bessemer, Homestead, Duquesne, Munhall, McKeesport
Cincinnati	Newport
St. Louis	Granite City, E. St. Louis, Madison, Ill.
Chicago	Gary
Claymont	Chester, Pa.
San Francisco	So. San Francisco, Niles, Oakland

MAXIMUM SHIPPING POINT PRICE: Where shipment is wholly or partially by rail or vessel, or combination of rail and vessel, the scrap is at shipping point when placed f.o.b. railroad or f.a.s. vessel. For motor vehicle shipments scrap is at shipping point when loaded. Then maximum shipping point price shall be: (a) For shipping point located within a basing point, prices shown in above table for scrap at basing point in which shipping point is located, minus applicable switching charge deduction shown in paragraph above labeled "Switching Charges." (b) For shipping points outside basing point, price listed in above table hereof for scrap at most favorable basing point, minus lowest charge for transportation from shipping point to such basing point by rail or water carrier or combination. Where vessel movement is involved, in lieu of established dock charge or any cost customarily incurred at the dock, 75c. per ton must be included as part of deduction in computing shipping point price; 50c. at Memphis; $1 at Great Lakes ports; and $1.25 at New England ports. If no established transportation rate exists for a portion of movement from shipping to basing point, actual charge or cost customarily incurred by shipper in such portion of movement shall be included as part of deduction in computing shipping point price. For exceptions see official order.

UNPREPARED SCRAP: For unprepared scrap, maximum prices shall be $3.50 (and in the case of the material from which No. 1, No. 2, and No. 3 bundles are made $4) less than maximum prices for the corresponding prepared scrap. In no case, however, shall electric furnace, acid open hearth and foundry grades be used as the corresponding prepared scrap. A preparation-in-transit charge for unprepared scrap is provided.

NEW LISTED GRADES: Priced in dollars per gross ton less than No. 1 heavy melting steel. Pit scrap, ladle skulls, slag reclaim, etc., of 85% or more Fe priced less $2; 75 to 85% Fe less $4; under 75% Fe less $8 per ton. Mill scale less $8 per ton. Mill cinder and grindings, shipping point maximum price of $4 per gross ton at all U. S. shipping points.

CHEMICAL BORINGS: No. 1 (new, clean, containing not more than 1% oil), $1 less than No. 1 heavy melting; No. 2 (new, clean, containing not more than 1.5% oil), $2 less than No. 1 heavy melting. If loaded in box cars add 75c. mill scale, $8 less than No. 1 heavy melting.

Tool Steel Scrap Prices (MPR 379)

	SEGREGATED Solids Per Lb. Cont. W	SEGREGATED Turnings Per Lb. Cont. W
Type 1. 12% min. W, 1% max. Mo	$1.80	$1.60
Type 2. 5 to 12% W, 1% max. Mo	1.60	1.40
Type 3. 1 to 5% W, 1.5% max. Mo	1.25	1.25
*Type 4. 7% min. Mo, 2% max. W	0.125	0.105
*Type 5. 3.5 to 6% Mo, 4.5 to 6% W	0.135	0.115

UNSEGREGATED SOLIDS: $1.50 per lb. contained W if 5% or more. $1.15 per lb. contained W if 1 to 5%. $0.80 per lb. contained Mo if 1.5% or more.

UNSEGREGATED TURNINGS: $1.30 per lb. contained W if 5% or more. $1.00 per lb. contained W if 1 to 5%. $0.70 per lb. contained Mo if 1.5% or more.

If both W and Mo are within ranges, payment may be for both W and Mo content.

*Per lb. of scrap material.

If segregated, a premium of $1.50 per lb. of contained Co allowed if Co content is 3% or over. No scrap considered segregated if Co content ranges between 0.5 and 3%.

If Cu or Ni content over 0.2o%, price shall be reduced by 50%.

If 500 lb. or less is sold, either segregated or unsegregated, price shall be reduced 2c. per lb. of scrap material.

Price schedules on railroad scrap and cast iron scrap will be carried in the last issue of each month.

The various basing points for finished and semi-finished steel are listed in the detailed price tables, pages 171-183.

Composite Prices . . .

Starting with the issue of April 22, 1943, the weighted finished steel price index was revised for the years 1941, 1942 and 1943. See explanation of the change on page 90 of the April 22, 1943, issue.

	FINISHED STEEL	PIG IRON	SCRAP STEEL
March 23, 1944	2.25513c. a Lb.	$23.61 a Gross Ton	$19.17 a Gross Ton
One week ago	2.25513c. a Lb.	$23.61 a Gross Ton	$19.17 a Gross Ton

Weighted index based on steel bars, beams, tank plates, wire, rails, black pipe, hot and cold-rolled sheets and strip, representing 78 per cent of the United States output. Index recapitulated in Aug. 28, 1941, issue.

Based on averages for basic iron at Valley furnaces and foundry iron at Chicago, Philadelphia, Buffalo, Valley and Southern iron at Cincinnati.

Based on No. 1 heavy melting steel scrap quotations to consumers at Pittsburgh, Philadelphia and Chicago.

. . . Prices of Finished Iron and Steel

Steel prices shown here are f.o.b. basing points, in cents per lb., unless otherwise indicated. Extras apply. Delivered prices do not reflect 3% tax on freight. (1) Mill run sheet, 10c. per 100 lb. under base; primes 25c. above base. (2) Unassorted 8-lb. coating. (3) Widths up to 12-in. (4) 0.25 carbon and less. (5) Applies to certain width and length limitations. (6) For merchant trade. (7) For straight length material only from producer to consumer. Discount of 25c. per 100 lb. to fabricators. (8) Also shafting. For quantities of 20,000 to 29,999 lb. (9) Carload lot in manufacturing trade. (10) Prices do not apply if rail and water is used. (12) Boxed. (13) Portland and Seattle price, San Francisco 2.50c. (14) This base price to be used in figuring annealed, bright finish wires, commercial spring wire.

EXCEPTIONS TO PRICE SCHED. NO. 6

Slabs—Andrews Steel Co. $41 basing pts.; Wheeling Steel Corp. $34 Portsmouth, Ohio; Empire Sheet & Tin Plate Corp. $41; Phoenix Iron Co. (rerolling) $41, (forging) $47; Granite City Steel Co. $47.50.

Blooms—Phoenix Iron Co. (rerolling) $41, (forging) $47.

Sheet Bar—Empire Sheet & Tin Plate Co. $39 mill; Wheeling Steel Corp. $38 Portsmouth, Ohio.

Billets, Forging—Andrews Steel Co. $50 basing pts.; Follansbee Steel Corp. $49.50 Toronto; Phoenix Iron Co. $47.00 mill.

Billets, Rerolling—Continental Steel Corp. may charge Acme Steel in Chicago switching area $34 plus freight from Kokomo, Ind.; Northwestern Steel & Wire Co. (Lend-Lease) $41 mill; Wheeling Steel Corp. (small) $36 Portsmouth, Ohio; (blooming mill sizes) applicable base, f.o.b. Portsmouth, Ohio; Stanley Works may sell Washburn Wire Co. under allocation at $39 Bridgeport, Conn.; Keystone Steel & Wire Co. may sell Acme Steel Co. at Chicago base, f.o.b. Peoria; Phoenix Iron Co. $41 mill; Continental Steel Corp. (1¾ x 1¾) $39.50, (2 x 2) $40.60 Kokomo, Ind. (these prices include $1 size extra); Keystone Steel & Wire Co. $36.40 Peoria; Connors Steel Co. $50.69 Birmingham; Ford Motor Co. $34 Dearborn, Mich.

Structural Shapes—Phoenix Iron Co. $2.35 basing pts., (export) $2.50 Phoenixville; Knoxville Iron Co. $2.30 basing pts.

Bar Size Shapes—(Angles) W. Ames & Co., 10 tons or over, $3.10 mill.

Rails—Sweet Steel Co. (rail steel) $50 mill; West Virginia Rail Co. (lightweight) on allocation based Huntington, W. Va.; Colorado Fuel & Iron Corp. $45 Pueblo.

Hot Rolled Plate—Granite City Steel Co. $2.65 mill; Knoxville Iron Co. $2.25 basing pts.; Kaiser Co. $3.20 Pacific Ports.

Merchant Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Eckels-Nye Steel Corp., $2.50 basing pts. (rail steel) $2.40; Phoenix Iron Co. $2.40 basing pts.; Sweet Steel Co. (rail steel) $2.35 mill; Joslyn Mfg. & Supply Co. $2.35 Chicago; Central Iron & Steel Co. $2.20 basing pts.; Granite City Steel Co. $2.35 Granite City; Calumet Steel Div., Borg Warner Corp. (8 in. mill bars) $2.35 Chicago; Knoxville Iron Co. $2.30 basing pts. Laclede Steel Co., sales to LaSalle Steel granted Chicago base, f.o.b. Madison, Ill.

Reinforcing Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Sweet Steel Co. (rail steel) $2.35 mill; Columbia Steel Co. $2.50 Pacific Ports.

Cold Finished Bars—Keystone Drawn Steel Co. on allocation, Pittsburgh c.f. base plus c/l freight on hot rolled bars Pittsburgh to Spring City, Pa.; New England Drawn Steel Co. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to Massfield, Mass., f.o.b. Massfield.; Empire Finished Steel Corp. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to plants f.o.b. plant; Compressed Steel Shafting Co. on allocation outside New England, Buffalo base plus c/l freight Buffalo to Readville, Mass. f.o.b. Readville; Medart Co. in certain areas, Chicago c.f. base plus c/l freight Chicago to St. Louis, f.o.b. St. Louis.

Alloy Bars—Texas Steel Co. for delivery except Texas and Okla. Chicago base, f.o.b. Fort Worth, Tex.; Connors Steel Co. shipped outside Ala., Mississippi, Louisiana, Georgia, Florida, Tenn., Pittsburgh base, f.o.b. Birmingham.

Hot Rolled Strip—Joslyn Mfg. & Supply Co. $2.30 Chicago; Knoxville Iron Co. $2.25 basing pts.

Hot Rolled Sheets—Andrews Steel Co., Middletown base on shipments to Detroit or area; Parkersburg Iron & Steel Co., $2.25 Parkersburg.

Galvanized Sheets—Andrews Steel Co., $3.75 basing pts.; Parkersburg Iron & Steel Co. $3.85 Parkersburg; Apollo Steel Co. $3.75 basing pts.; Continental Steel Co., Middletown base on Kokomo, Ind., product; Superior Sheet Steel Co., Pittsburgh base except for Lend-Lease.

Pipe and Tubing—South Chester Tube Co. when priced at Pittsburgh, freight to Gulf Coast and Pacific Ports may be charged from Chester, Pa., also to points lying west of Harrisburg, Pa.

Black Sheets—Empire Sheet and Tinplate Co., maximum base price mill is $2.45 per 100 lb., with differentials, transportation charges, etc., provided in RPS. No. 6.

WAREHOUSE PRICES

Delivered metropolitan areas per 100 lb. These are zoned warehouse prices in conformance with latest zoning amendments to OPA Price Schedule 49.

*Recommended for large sections only. Note: The extras shown are in addition to a base price of 2.70c. per 100 lb., on finished products and $54 per gross ton on semi-finished steel major basing points and are in cents per 100 lb. and dollars per gross ton in semi-finished. When acid open-hearth is specified and acceptable add to basic open hearth alloy differential 0.25c. per lb. for bars and bar strip, $5.00 per gross ton for billets, blooms and slabs. The ranges shown above are restricted to sizes 100 sq. in. or less or equivalent cross sectional area 18 in. wide or under with a max. individual piece weight of 7000 lb.

BASE QUANTITIES

Standard unless otherwise keyed on prices.

HOT ROLLED: Sheets, strip, plates, shapes and bars, 400 to 1999 lb.

COLD ROLLED: Sheets, 400 to 1499 lb.; strip, extras on all quantities; bars, 1500 lb. base; NE alloy bars, 1000 to 39,999 lb.

EXCEPTIONS: (1) 150 to 499 lb. (2) 150 to 1499 lb. (3) 400 to 1499 lb. (4) 450 to 1499 lb. (5) 500 to 1499 lb. (6) 0 to 1999 lb. (7) 400 to 1999 lb. (8) 1000 to 1999 lb. (9) 450 to 3749 lb. (10) 400 to 3999 lb. (11) 300 to 4999 lb. (12) 300 to 10,000 lb. (13) 400 to 14,999 lb. (14) 400 lb. and over. (15) 1000 lb. and over. (16) 1500 lb. and over. (17) 2000 lb. and over. (18) 3500 lb. and over.

(a) Philadelphia: Galvanized sheets, 25 or more bundles.

Extra for size, quality, etc., apply on above quotations.

*Add 0.271c. for sizes not rolled in Birmingham.

**City of Philadelphia only. Applicable freight rates must be added to basing point prices to obtain delivered price to other localities in metropolitan area.

LAKE SUPERIOR ORES

(51.50% *Fe, Natural Content, Delivered Lower Lake Ports)**

	Per Gross Ton
Old range, bessemer, 51.50	$4.75
Old range, non-bessemer, 51.50	4.60
Mesaba, bessemer, 51.50	4.60
Mesaba, non-bessemer, 51.50	4.45
High phosphorus, 51.50	4.35

*Adjustments are made to indicate prices based on variance of Fe content of ores as analyzed on a dry basis by independent laboratories.

FLUORSPAR

Maximum price f.o.b. consumer's plant, $30 per short ton plus either (1) rail freight from producer to consumer, or (2) rail freight from Rosiclare, Ill., to consumer, whichever is lower.

Exception

When the WPB Steel Division certifies in writing the consumer's need for one of the higher grades of metallurgical fluorspar specified in the table below the price shall be taken from the table plus items (1 and 2) from paragraph above.

Effective CaF_2 Content:	*Base price per short ton*
70% or more	$33.00
65% but less than 70%	32.00
60% but less than 65%	31.00
Less than 60%	30.00

PRICES

SEMI-FINISHED STEEL

Ingots, Carbon, Rerolling

Base per gross ton, f.o.b. mill.... $34.00
Exceptions: Phoenix Iron Co. may charge $38.75; Kaiser Co., $43.00 f.o.b. Pacific Coast Ports; Empire Sheet & Tinplate Co., $34.25.

Ingots, Carbon, Forging

Base per gross ton, f.o.b. Birmingham, Buffalo, Chicago, Cleveland, Gary, Pittsburgh, Youngstown $36.00
Exceptions: Phoenix Iron Co. may charge $43.00; Empire Sheet & Tinplate Co., $39.25, f.o.b. Mansfield, Ohio; West Coast producers, $48.00, f.o.b. Pacific Coast Ports.

Ingots, Alloy

Base per gross ton, f.o.b. Bethlehem, Buffalo, Canton, Coatesville, Chicago, Massillon, Pittsburgh $45.00
Exceptions: C/L delivered Detroit add $2.00; delivered East Michigan add $3.00. Connors Steel Co. may charge $45.00 f.o.b. Birmingham.

Billets, Blooms and Slabs

Pittsburgh, Chicago, Gary, Cleveland, Youngstown, Buffalo, Birmingham, Sparrows Point (rerolling only). Prices delivered Detroit are $2.00 higher; delivered E. Michigan, $3 higher; f.o.b. Duluth, billets only, $2.00 higher; billets f.o.b. Pacific ports are $12 higher. Delivered prices do not reflect three per cent tax on freight rates.

	Per Gross Ton
Rerolling	$34.00
Forging quality	40.00

For exceptions on semi-finished steel see the footnote on the page of finished steel prices.

Alloy Billets, Blooms, Slabs

Pittsburgh, Chicago, Canton, Massillon, Buffalo, or Bethlehem, per gross ton 54.00
Price delivered Detroit $2.00 higher; E. Michigan $3.00 higher.

Shell Steel

	Per Gross Ton
8 in. to 12 in.	$52.00
12 in. to 18 in.	54.00
18 in. and over	56.00

Basic open hearth shell steel, f.o.b. Pittsburgh, Chicago, Buffalo, Gary, Cleveland, Youngstown and Birmingham.
Prices delivered Detroit are $2.00 higher; E. Michigan, $3 higher.
Note: The above base prices apply on lots of 1000 tons of a size and section to which are to be added extras for chemical requirements, cutting, or quantity.

Sheet Bars

Pittsburgh, Chicago, Cleveland, Youngstown, Buffalo, Canton, Sparrows Point.

	Per Gross Ton
Open hearth or bessemer	$34.00

Skelp

Pittsburgh, Chicago, Youngstown, Coatesville, Pa., Sparrows Point, Md.

	Per Lb.
Grooved, universal and sheared	1.90c.

Wire Rods

(No. 5 to 9/32 in.)

	Per Lb.
Pittsburgh, Chicago, Cleveland	2.00c.
Worcester, Mass.	2.10c.
Birmingham	2.00c.
San Francisco	2.50c.
Galveston	2.25c.

9/32 in. to 47/64 in., 0.15c. a lb. higher. Quantity extras apply.

TOOL STEEL

(F.o.b. Pittsburgh, Bethlehem, Syracuse)

	Base per lb.
High speed	67c.
Straight molybdenum	54c.
Tungsten-molybdenum	57½c.
High-carbon-chromium	43c.
Oil hardening	24c.
Special carbon	22c.
Extra carbon	18c.
Regular carbon	14c.

Warehouse prices east of Mississippi are 2c. a lb. higher; west of Mississippi 1c. higher.

UNISHEARS Cut Sheet Metal *Faster!*

Stanley Unishears cut sheet materials as fast as you feed, up to 15 feet per minute – follow any line accurately, straight, curved or angle – leaving smooth, clean edges with no waste of material. Plenty rugged for tough production or maintenance use.

Portable Unishears are made in four models – for 18 gauge, 16 gauge, 14 gauge and 12 gauge hot rolled steel or galvanized iron. Stationary Unishears are also available to cut 14 gauge and 10 gauge sheets. Write for literature. Stanley Electric Tool Division, The Stanley Works, New Britain, Connecticut.

Stanley Unishears No. 214 – Cutting capacity 14 gauge hot rolled steel.

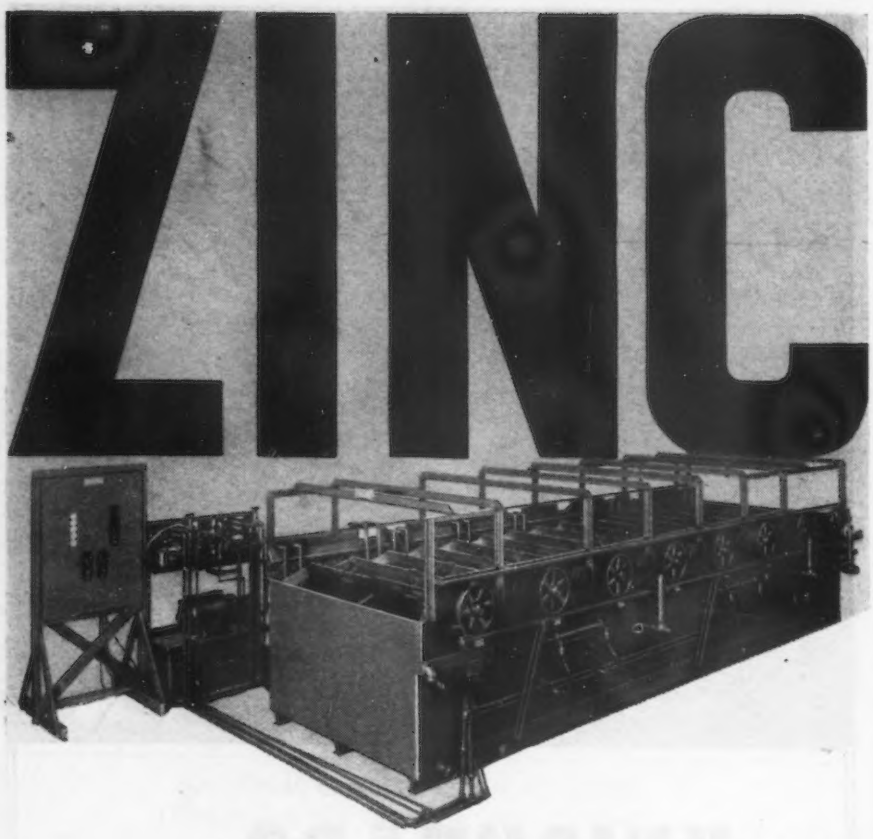
Electrically Driven Metal Shears



BY UDYLITE

Udylite's years of experience with this practical, inexpensive, protective coating is yours for the asking.

We have the process, nationally known for its efficiency and performance; the equipment, for both plating and dichromating; and the supplies, from chemicals to the efficient ball anode which is an exclusive Udylite development.

The above automatic dichromating machine is a Udylite development for the processing of large quantities of small parts through the complete cycle, from initial rinse to ultimate heat treat. The machine is capable of handling approximately 10 cu. ft. of volume per hour, with excellent uniformity and a minimum of scarring.

Investigate "Zinc by Udylite"—your inquiry will receive our prompt attention.

THE UDYLITE CORPORATION

1651 E. Grand Blvd., Detroit 11, Mich.

Chicago 12, 1943 Walnut Street | Long Island City 1, N. Y., 11-16 44th Drive | Cleveland 3, 4408 Carnegie Ave.

PRICES

WELDED PIPE AND TUBING

Base Discounts, f.o.b. Pittsburgh District and Lorain, Ohio, Mills

(F.o.b. Pittsburgh only on wrought pipe)
Base Price—$200 per Net Ton

	Black	Galv.
Steel (Butt Weld)		
⅛ in.	63½	51
¼ in.	66½	55
⅜ to 3 in.	68½	57½
Wrought Iron (Butt Weld)		
⅛ in.	24	3½
¼ in.	30	10

GRAY FORGE IRON: Valley or Pittsburgh furnace $23.50

(1) Pittsburgh Coke & Iron Co. (Sharpsville, Pa., furnace only) and the Struthers Iron and Steel Co., Struthers, Ohio, may charge 50c. a ton in excess of basing point prices for No. 2 foundry, basic, bessemer and malleable. Struthers Iron and Steel Co. may add another $1.00 per gross ton for iron from Struthers, Ohio, plant.

(2) Price shown is for low-phosphorous iron; high phosphorous sells for $28.50 at the furnace.

(3) E. & G. Brooke Co. Birdsboro, Pa., permitted to charge $1.00 per ton extra.

(4) Pittsburgh Ferromanganese Co. (Chester furnace only) may charge $2.25 a ton over maximum basing point prices.

Basing point prices are subject to switching charges; Silicon differentials (not to exceed 50c. a ton for each 0.25 per cent silicon content in excess of base grade which is 1.75 to 2.25 per cent); Phosphorus differentials, a reduction of 38c. per ton for phosphorus content of 0.70 per cent and over; Manganese differentials, a charge not to exceed 50c. per ton for each 0.50 per cent manganese content in excess of 1.00 per cent. Effective March 3, 1943, $2 per ton extra may be charged for 0.5 to 0.75 per cent nickel content and $1 per ton extra for each additional 0.25 per cent nickel.

METAL POWDERS

Prices are based on current market prices of ingots plus a fixed figure. F.o.b. shipping point, c. per lb., ton lots.

Copper, electrolytic, 150 and 200 mesh	21⅛ to 23½c.
Copper, reduced, 150 and 200 mesh	20½ to 25½c.
Iron, commercial, 100 and 200 mesh, 96 + % Fe	13½ to 15c.
Iron, crushed, 200 mesh and finer, 90 + % Fe	4c.
Iron, hydrogen reduced, 300 mesh and finer, 98½ + % Fe	63c.
Iron, electrolytic, unannealed, 300 mesh and coarser, 99 + % Fe	30 to 33c.
Iron, electrolytic, annealed minus 100 mesh, 99 + % Fe	42c.
Iron, carbonyl, 300 mesh and finer, 98-99.8 + % Fe	90c.
Aluminum, 100 and 200 mesh	*23 to 27c.
Antimony, 100 mesh	20.6c.
Cadmium, 100 mesh	$1
Chromium, 150 mesh	$1.03
Lead, 100, 200 & 300 mesh, 11½ to 12½c.	
Manganese, 150 mesh	51c.
Nickel, 150 mesh	51½c.
Solder powder, 100 mesh, 8½c. plus metal	
Tin, 100 mesh	58¾c.
Tungsten metal powder, 98%-99%, any quantity, per lb.	$2.60
Molybdenum power, 99%, in 200-lb. kegs, f.o.b. York, Pa., per lb.	$2.60
Under 100 lb.	$3.00

*Freight allowed east of Mississippi.

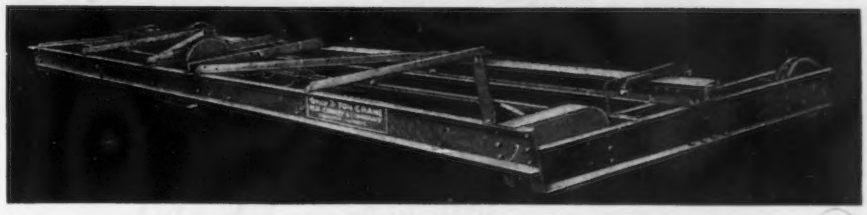
ELECTRICAL SHEETS
(Base, f.o.b. Pittsburgh)

	Per Lb.
Field grade	3.20c.
Armature	3.55c.
Electrical	4.05c.
Motor	4.95c.
Dynamo	5.65c.
Transformer 72	6.15c.
Transformer 65	7.15c.
Transformer 58	7.65c.
Transformer 52	8.45c.

F.o.b. Granite City, add 10c. per 100 lb. on field grade to and including dynamo. Pacific ports add 75c. per 100 lb. on all grades.

CONCO 3-Motor Single Girder CAB OR FLOOR OPERATED ELECTRIC CRANE . . .



● Available in capacities of one through five tons for floor or cab operation. Simply, ruggedly designed for low first cost and maintenance. Used with Low Headroom Type Hoist, provides for maximum space coverage horizontally and vertically. Effective in even a minimum space. Write for Bulletin 2000.

Write for Bulletin 26000 describing the Torpedo Hoist shown. Three capacities 250 lb. — $139.50, 500 lb. — $149.50, 1000 lb. — $159.50. Heavily, simply built, with Push Button Control. Outstanding in CONCO'S complete line of hand-powered and electric Cranes, Hoists, Trolleys.

HEAT-TREATED STEEL SHOT

We manufacture shot and grit for endurance

A shot or grit that will blast fast with a clean finish.

This is the only reason why so many operators are daily changing to our shot and grit, from Maine to California.

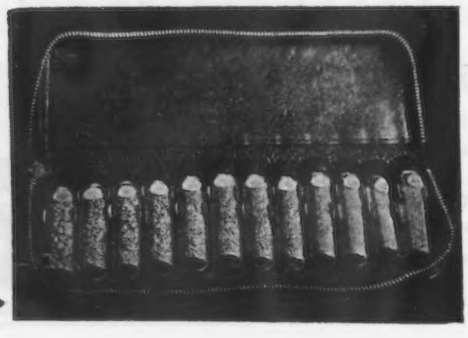
The unprecedented demand for our—

Heat-Treated Steel Shot and Heat-Treated Steel Grit

has enabled us to expand our production and maintain a quality that is more than satisfactory to our hundreds of customers all over the country.

HARRISON ABRASIVE CORPORATION

Manchester, New Hampshire



HEAT-TREATED STEEL GRIT

PRICES

Ferromanganese

78-82% Mn, maximum contract base price per gross ton, lump size, f.o.b. car at Baltimore, Bethlehem, Philadelphia, New York, Birmingham, Rockdale, Rockwood, Tenn.

Carload lots (bulk) $135.00
Carload lots (packed) 141.00
Less ton lots (packed) 148.50

Premium, $1.70 for each 1% above 82% Mn; penalty, $1.70 for each 1% below 78%.

Manganese Metal

Contract basis, lump size, per lb of metal, f.o.b. shipping point with freight allowed. Spot sales add 2c. per lb.

96-98% Mn, .2% max. C, 1% max. Si, 2% max. Fe.

Carload, bulk ..... 36c.
L.c.l. lots ..... 38c.

95-97% Mn, .2% max. C, 1.5% max. Si, 2.5% max. Fe.

Carload, bulk ..... 34c.
L.c.l. lots ..... 35c.

Spiegeleisen

Maximum base, contract prices, per gross ton, lump, f.o.b. Palmerton, Pa.

	16-19% Mn 3% max. Si	19-21% Mn 3% max. Si
Carloads	$35.00	$36.00
Less ton	47.50	48.50

Electric Ferrosilicon

OPA maximum base price cents per lb. contained Si, lump size in carlots, f.o.b. shipping point with freight allowed to destination.

	Eastern Zone	Central Zone	Western Zone
50% Si ...	6.65c.	7.10c.	7.25c.
75% Si ...	8.05c.	8.20c.	8.75c.
80-90% Si ...	8.90c.	9.05c.	9.55c.
90-95% Si ...	11.05c.	11.20c.	11.65c.

Spot sales add: 45c. per lb. for 50% Si, .3c. per lb. for 75% Si, .25c. per lb. for 80-90% and 90-95% Si.

Silvery Iron

(Per Gross Ton, base 6.00 to 6.50 Si)

F.o.b. Jackson, Ohio $29.50*
Buffalo 30.75*

For each additional 0.50% silicon add $1 a ton. For each 0.50% manganese over 1% add 50c. a ton. Add $1 a ton for 0.75% phosphorous or over.

*OPA price established 6-24-41.

Bessemer Ferrosilicon

Prices are $1 a ton above silvery iron quotations of comparable analysis.

Silicon Metal

OPA maximum base price per lb. of contained Si, lump size, f.o.b. shipping point with freight allowed to destination, for l.c.l. above 2000 lb., packed. Add .25c. for spot sales.

	Eastern Zone	Central Zone	Western Zone
96% Si, 2% Fe.	13.10c.	13.55c.	16.50c.
97% Si, 1% Fe.	13.45c.	13.90c.	16.80c.

Ferrosilicon Briquets

OPA maximum base price per lb. of briquet, bulk, f.o.b. shipping point with freight allowed to destination. Approximately 40% Si. Add .25c. for spot sales.

	Eastern Zone	Central Zone	Western Zone
Carload, bulk	3.35c.	3.50c.	3.65c.
2000 lb.-carload	3.8c.	4.2c.	4.25c.

Silicomanganese

Contract basis lump size, per lb. of metal, f.o.b. shipping point with freight allowed. Add .25c. for spot sales. 65-70% Mn, 17-20% Si, 1.5% max. C.

Carload, bulk ..... 6.05c.
2000 lb. to carload ..... 6.70c.
Under 2000 lb. ..... 6.90c.
Briquets, contract, basis carlots, bulk freight allowed, per lb..... 5.80c.
2000 lb. to carload ..... 6.30c.
Less ton lots ..... 6.55c.

Ferrochrome

(65-72% Cr, 2% max. Si)

OPA maximum base contract prices per lb. of contained Cr, lump size in carload lots, f.o.b. shipping point, freight allowed to destination. Add .25c. per lb. contained Cr for spot sales.

	Eastern Zone	Central Zone	Western Zone
0.06% C	23.00c.	23.40c.	24.00c.
0.10% C	22.50c.	22.90c.	23.50c.
0.15% C	22.00c.	22.40c.	23.00c.
0.20% C	21.50c.	21.90c.	22.50c.
0.50% C	21.00c.	21.40c.	22.00c.
1.00% C	20.50c.	20.90c.	21.50c.
2.00% C	19.50c.	19.90c.	21.00c.
66-71% Cr. 4-10% C	13.00c.	13.40c.	14.00c.

Other Ferroalloys

Ferrotungsten, Standard grade, lump or ¼X down, packed, f.o.b. plant at Niagara Falls, New York, Washington, Pa., York, Pa., per lb. contained tungsten. 10,000 lb. of more... $1.90

Ferrovanadium, 50-55%, contract basis, f.o.b. producer's plant, usual freight allowances, per lb. contained Va.
- Open Hearth $2.70
- Crucible $2.80
- Primos $2.90

Cobalt, 97% min., keg packed, contract basis, f.o.b. producer's plant, usual freight allowances, per lb. of cobalt metal $1.50

Vanadium pentoxide, 88%-92% V_2O_5 technical grade, contract basis, any quantity, per lb. contained V_2O_5. Spot sales add 5c. per lb. contained V_2O_5 ..... $1.10

Ferroboron, contract basis, 17.50% min. Bo, f.o.b. producer's plant with usual freight allowances, per lb. of alloy.
- 2000 lb. to carload $1.20
- Under 2000 lb. 1.30
- Per lb. alloy $1.20
- Ton lots $1.25

Silcaz No. 3, contract basis, f.o.b. producer's plant with usual freight allowances, per lb. of alloy. (Pending OPA approval)
- Carload lots ..... 25c.
- 2000 lb. to carload ..... 26c.

Silvaz No. 3, contract basis, f.o.b. producer's plant with freight allowances, per lb. of alloy (Pending OPA approval)
- Carload lots ..... 58c.
- 2000 lb. to carload ..... 59c.

Grainal No. 1, f.o.b. Bridgeville, Pa., freight allowed 50 lb. and over, max. based on rate to St. Louis, per lb. ..... 87.5c.

Bortram, f.o.b. Niagara Falls
- Ton lots, per lb. ..... 45c.
- Less ton lots, per lb. ..... 50c.

Ferrocolumbium, 50-60%, contract basis, f.o.b. plant with freight allowances, per lb contained Cb.
- 2000 lb. lots $2.25
- Under 2000 lb. lots $2.30

Ferrotitanium, 40%-45%, f.o.b. Niagara Falls, N. Y., ton lots, per lb. contained titanium ... $1.23
- Less ton lots $1.25

Ferrotitanium, 20%-25%, 0.10 C max., ton lots, per lb. contained titanium $1.35
- Less ton lots $1.40

High-carbon ferrotitanium, 15%-20%, 6%-8% carbon, contract basis, f.o.b. Niagara Falls, N. Y., freight allowed East of Mississippi River, North of Baltimore and St. Louis, per carload $142.50

Ferrophosphorus, 18% electric or blast furnace, f.o.b. Anniston, Ala., carlots, with $3 unitage freight equaled with Rockdale, Tenn., per gross ton $58.50

Ferrophosphorus, electrolytic 23-26%, carlots, f.o.b. Monsanto (Siglo), Tenn., $3 unitage freight equalized with Nashville, per gross ton $75.00

Ferromolybdenum, 55-75%, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained molybdenum ..... 95c.

Calcium molybdate, 40%-45%, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained Mo ..... 80c.

Molybdenum oxide briquettes, 48%-52% Mo, f.o.b. Langeloth, Pa., per lb. contained Mo ..... 80c.

Molybdenum oxide, in cans, f.o.b. Langeloth and Washington, Pa., per lb. contained Mo ..... 80c.

Zirconium, 35-40%, contract basis, f.o.b. producer's plant with freight allowances, per lb. of alloy. Add ¼c. for spot sales
- Carload lots ..... 14c.

Zirconium, 12-15%, contract basis, lump, f.o.b. plant with usual freight allowances, per lb. of alloy
- Carload, bulk ..... 4.6c.

Alsifer (approx. 20% Al, 40% Si and 40% Fe), contract basis, f.o.b. Niagara Falls, carload, bulk ..... 6.5c.
- Ton lots ..... 7.25c.

Simanal (approx. 20% Si, 20% Mn, 20% Al), contract basis, f.o.b. Philo, Ohio, with freight not to exceed St. Louis rate allowed, per lb.
- Car lots ..... 8.75c.
- Ton lots ..... 9.25c.

NATIONAL
ALUMINUM MFG. CO., PEORIA, ILL.

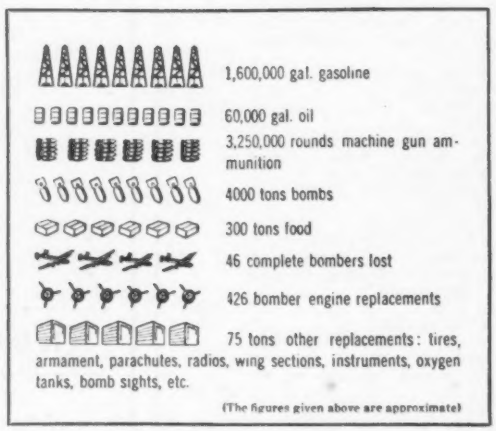
This advertisement is one of a series which is appearing in national magazines and newspapers as Consolidated Vultee's contribution toward a clearer public understanding of transportation's role in the war, and its postwar opportunities and responsibilities.

As a Liberator pilot put it:

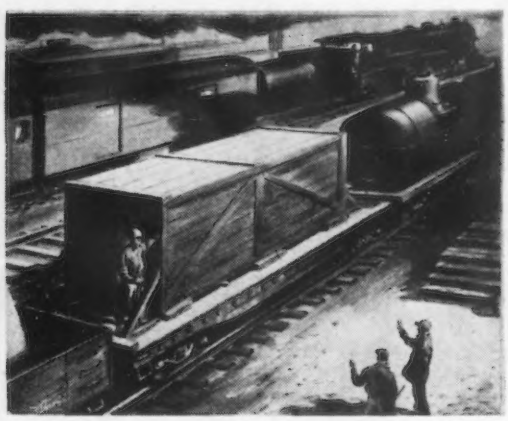
"One of their cities is missing!"

1, 40 minutes ago, there were Nazi factories down there building Focke-Wulf 190's and machine guns. Now there are no factories. Not even a city. For the last of 1000 Allied bombers has just dropped its block busters and is heading for home.

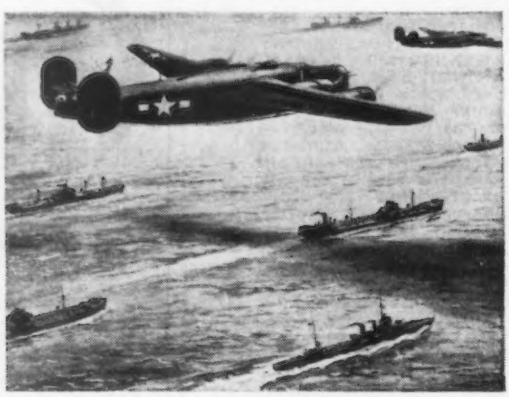
Back of this 1000-bomber sweep is a story not many people know—a story quite apart from that of the heroism and sacrifice of the bomber crews. It has to do with the terrific problem of supply in waging aerial warfare. For example...



2, Above, you get a rough idea of the cost, *in material alone,* to send 1000 4-engine bombers over Germany. How can Bomber Command get *another* 300 tons of food...*1 day's supply for the 150,000 men it takes to put 1000 bombers over the target?* Another 160 tank cars of aviation gasoline? Another 4000 tons of bombs? Not just for tomorrow, but for the next day, and the next. *Answer:* That's where Air Power's three teammates come into the picture—the train, truck, and ship . . .



3, If your sleeper is shunted to a siding, remember this: It is probably being held up to let a fast freight streak through — tank cars of gasoline, cars loaded with spare bomber parts, engines, crates of nested bombs, tons of food, ammunition, and all the rest. Getting Bomber Command's supplies from factory to seaboard is the first lap in a 1000-bomber attack on Germany. And in this relay race to Victory, the railroads of America are doing a magnificent job!



4, Slogging along at a snail's pace, protected by anti-submarine Liberators, a never-ending convoy of cargo ships and tankers becomes the life stream of Air Power. They bridge the Atlantic with supplies and replacements to *keep* the bombers fanning out over Germany. This link in the chain of supply must never be broken. If a cargo is sunk on the way over, Air Service Command and the Navy move heaven and earth to get an exact duplicate cargo loaded into another ship and on its way within 48 hours!

CONSOLIDATED VULTEE
